Uses.—Rhatany is an active astringent, and may be advantageously given in *chronic diarrhea.* It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. In the form of infusion, tincture, or extract, rhatany has been used locally in *fissure of the anus, prolapsus ani,* and *leucorrhea.*

Dose, of the powder, twenty to thirty grains (1.3–2.0 Gm.).

LACTUCARIUM. U. S.

LACTUCARIUM Lactucar.

(lăc-tū-cā′rĭ-ŭm)

"The dried milk-juice of *Lactuca virosa* Linné (Fam. *Compositæ*)." *U. S.*

Lactucarium Anglicum, Lactucarium Germanicum; Strong-scented Lettuce, Green Endive; Lactucarium, *Fr. Cod.;* Giftlattichsaft, *G.;* Lactucario, *Sp.*

The plants of this genus yield when wounded a milky-juice, to which, indeed, they owe their generic name. The juice from *L. sativa, L. virosa,* and *L. altissima* Bieberstein has been supposed to possess narcotic properties.

Lactuca sativa or *garden lettuce* is an annual plant. The stem, which rises above two feet, is erect, round, simple below, and branching in its upper part. The lower leaves are obovate, undulate and rounded at the summit; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green color. The flowers are pale yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland pellucid juice, has little taste or odor, and is much used as a salad for the table, but during the period of inflorescence it abounds in a milky juice, which readily escapes from incisions in the stem. The juice is more abundant in the wild than in the cultivated plants. The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and flourishes equally in hot and temperate latitudes. Some botanists suppose that *L. virosa* of the old continent is the parent of all the varieties of the cultivated plant.

Lactuca virosa, the *acrid* or *strong-scented lettuce*, is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong-ovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bracts are cordate and pointed. The flowers are numerous, of a sulphur-yellow color, and disposed in a panicle. The plant is a native of Europe.

It is lactescent, and has a strong disagreeable odor like that of opium, and a bitterish, acrid taste.

Lactucarium is cultivated in Scotland, Germany, Austria and France. According to Fairgrieve (*P. J.*, 1873, iii, p. 972) the plant cultivated in Scotland is the *L. virosa*, var. *montana*. From May to August, or even as late as September, the collectors spread over the field cutting the head of each stalk and scraping the flow into their vessels. This is repeated several times daily until the plants are exhausted. The method of cultivation in the Mosel Valley, Germany, is described by Kieffer (*Ph. Zeit.*, i, p. 143), who states that the drug of Germany is shipped to England and later imported into the United States via San Francisco, where it is supposedly used in the adulteration of opium. The cultivation in France is described by Van Italie (*J. P. C.*, 1913, viii, p. 449).

For various plans which have been suggested for collecting the drug, see 14th ed., *U. S. D.*

Lactucarium, as brought from England, is in small, irregular lumps, about the size of a pea or larger, of a reddish-brown color externally, and of a narcotic odor and bitter taste. As prepared near Edinburgh, it is commonly in roundish, compact, and rather hard masses, weighing several ounces. (Christison.) A variety known in our market as *German lactucarium* is in pieces about 4 cm. long by 2.5 cm. in thickness, four-sided, with one side convex and the three others flat, or slightly concave from shrinking, as if quarter sections of a saucer-shaped cake which had been divided before it was quite dry. The color on the outer or convex surface is darkish brown, that of the cut surfaces light yellowish-brown. From experiments by Parrish and Bakes, the German appears to be inferior to the English, as 44 per cent. of spirituous extract was obtained from the latter, and only 36 per cent. from the former, while the two extracts were about equal in their sensible properties. (*A. J. P.*, 1860, p. 226.) French lactucarium resembles the German, except in being in circular cakes about 4 cm. in diameter. The official description is as follows: "Usually in quarter sections of hemispherical masses, or in irregular, angular pieces; externally dull reddish- or grayish-brown; fracture tough, waxy; internally light brown or yellowish; somewhat porous; odor distinctive, opium-like; taste bitter. Lactucarium is partly soluble in alcohol and ether and, when triturated with water, it yields a turbid mixture. Treat Lactucarium with boiling water and filter; the filtrate is clear while hot; on cooling it becomes turbid but clears upon the addition of ammonia water or alcohol; it is not colored blue by iodine T.S. (*starch*). An alcoholic solution of Lactucarium gives not more than a faint green color upon the addition of a drop of ferric chloride T.S. (*tannin*). The powder is grayish-brown to dark brown, consisting almost entirely of irregular fragments without any cellular structure: when mounted in hydrated chloral T.S., the fragments become clear, showing granular fragments, and from this deposit, numerous rod-shaped crystals and broad monoclinic prisms as well as aggregates of these, all of which polarize light. In the preparation of powdered Lactucarium, dry the crude drug at a temperature not exceeding 70° C. (158° F.). Lactucarium contains not more than 15 per cent. of moisture, and yields not more than 10 per cent. of ash." *U. S.*

The *thridace* of François, at one time supposed to be identical with lactucarium, is in all probability nothing more than the inspissated expressed juice of lettuce, and, indeed, was directed as such in the French Codex of 1837, the leaves being rejected, and the stalks alone, near the flowering period, being subjected to pressure.

The drug of commerce usually has a growth of mold on the surface. If it has penetrated the drug to any extent it reduces its quality. Occasionally specimens are met with that are moldy throughout, and these should be rejected. In color, taste, and odor, lactucarium bears considerable resemblance to opium, and has sometimes been called *lettuce opium*. It does not attract moisture from the air. It yields nearly half its weight to water, with which it forms a deep-brown infusion. It is partly soluble in ether and alcohol. From its resemblance in some of its properties and to opium, it was conjectured to contain morphine, or some analogous principle, but this conjecture is false. There is no doubt as to the complexity of the composition of lactucarium, but so feeble are its properties that it has largely gone out of active use, and its chemistry is of little practical importance. Buchner, Aubergier, and Walz claim severally to have discovered the active principle, which has been named *lactucin*, but the substances obtained by these different chemists are not exactly identical in properties, and the lactucin of Walz and Aubergier is considered by Lenoir as owing its bitterness to impurities, separated from which it is without taste and inert. For a full account of the earlier analyses of lactucarium, see 16th edition, *U. S. D.* Ludwig found, in 100 parts, 48.63 of substances insoluble in water, and 51.37 of substances soluble in water. Of the insoluble matter 42.64 parts were of *lactucerin* or *lactucon*, in snow-white aggregated granules, dissolving in strong hot alcohol which deposits it on cooling, readily soluble in ether but insoluble in water, incapable of saponification by potassium hydroxide, and therefore not properly a fat, and in alcoholic solution faintly reddening litmus paper. On

the other hand, Hesse states that lactucon which, according to Massner, has the composition $C_{28}H_{44}O_2$, is a mixture of esters, of which one, $C_{36}H_{58}O_2(C_2H_3O)_2$, is a diacetyl ester yielding, when saponified, *α-lactucerol,* $C_{36}H_{60}O_2$, and acetic acid, while the other is a mono-acetyl ester, $C_{36}H_{59}O_2(C_2H_3O)$. Of the 51.37 parts soluble in water, 6.98 were albumen, 1.75 lactucerin, held in solution by other substances, 27.68 bitter extract soluble in water and in alcohol, and 14.96 aqueous extract insoluble in alcohol of 0.830. The former of these extracts was found to contain a peculiar acid substance called *lactucic acid,* and the lactucin of Aubergier. *Lactucic acid* is of difficult crystallization, light yellow, strongly bitter, without sour taste, of an acid reaction, and readily soluble in alcohol and water. It has as much claim as any other discovered substance to be considered the active principle of lactucarium.

The assertion sometimes made that *Lactuca virosa* contains a mydriatic alkaloid has been denied by J. C. Braithwaite and H. E. Stevenson, *P. J.*, 1903, 148. Farr and Wright (*P. J.*, 1904, p. 16) claim, however, to have definitely established the presence of a mydriatic alkaloid, giving alkaloidal reactions with Mayer's and Thresh's reagents, and producing a powerful mydriatic effect upon the eye.

Kromayer (*Ann. Ch. Ph.*, cv, p. 3) found also *lactucopikrin,* $C_{44}H_{32}O_{21}$, a brown, amorphous, and very bitter substance of weak acid reaction. It is easily soluble in water and alcohol. Ludwig's lactucic acid Kromayer considers to be an oxidation product of lactucopikrin.

Hesse (*Handwörterbuch,* iv, p. 8) prepared *lactucerin,* and finds it to crystallize in white needles, fusing point 210° C. (410° F.), soluble in hot ligroin, chloroform, and benzene. On fusion with potassium hydroxide it yields acetic acid and *lactuceryl alcohol,* $C_{18}H_{30}O$, which forms white needles, fusing at 162° C. (323.6° F.), and is easily soluble in ether, chloroform, and hot alcohol. Hesse has since (*Ann. Ch. Ph.*, 234, p. 243) determined that lactucarium contains the acetates of *α-* and *β-lactucerol,* $C_{18}H_{30}O$. These compound ethers are saponified with alcoholic potash and water added, which precipitates *α-* and *β-*lactucerol. These are washed, dried in the air, and taken up with boiling alcohol. On cooling, *α-*lactucerol separates out first and can be purified by recrystallization, while the *β-*lactucerol is obtained from the mother liquor. The acetate of *α-*lactucerol fuses at 210° C. (410° F.), while that of *β-*lactucerol fuses at 230° C. (446° F.). For an examination of *Russian lactucarium,* by L. Schiperovitch, see *Ph. Z. R.*, or *D. C.*, 1886.

Uses.—The ancients believed that lettuce had soporific properties, and many years ago J. R. Coxe, of Philadelphia, first proposed the employment of the inspissated milky juice as a medicine. It was chiefly, however, through the recommendation by Duncan, Sr., of Edinburgh, that the medicine came into use and was adopted as official in various pharmacopœias. It is claimed for it that it has, although in a very much inferior degree, the anodyne and calming properties of opium, without its disposition to derange the digestive organs. It has been employed in this country to some extent to allay *cough* and quiet *nervous irritation,* but we believe that the general experience is in accord with our own in finding it to be almost devoid of narcotic properties. We have never been able to obtain any good results from its use. Water distilled from lettuce (*eau de laitue*) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasm. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use. (See *Syrupus Lactucarii.*)

Dose, ten to twenty grains (0.65–1.3 Gm.), but much larger quantities may be given without obvious effects.

Off. Prep.—Syrupus Lactucarii (from Tincture), *U. S.;* Tinctura Lactucarii, *U. S.*

LAMELLÆ.

DISCS

(lą-mĕl'læ)

Gelatina Medicata in Lamellis; Medicated Gelatin Disks; Disques de Gélatine, *Fr.;* Gelatinlamellen, Gelatinplättchen, *G.*

Under this head are included in the British Pharmacopœia minute *gelatin discs* which contain traces of alkaloids, and which are designed to be inserted by oculists under the eyelid, in order to produce, through solution in the tears, such effects as they desire. A hot solution of gelatin containing the alkaloid in proper proportion is poured on a slightly greased or waxed glass or porcelain plate, cooled and dried, and then cut into discs, which, by previous calculation, will be found to contain the requisite quantity of medicament. A little glycerin is added to keep them from getting too hard and dry.

In Appendix X, British Pharmacopœia, a general formula is inserted as follows:

"Process for Preparation of Discs (Lamellæ), Br.—Discs are prepared by the following process:—Gelatin, 18 *grammes;* Glycerin, 2 *grammes;* Distilled Water, 88 *grammes.* Mix the Glycerin with the Distilled Water, allow the Gelatin to soak in the mixture till soft, and then dissolve by a gentle heat; cool the basis so produced. Take the prescribed quantity of the above basis, melt it by a gentle heat, add the prescribed quantity of medicament, dissolve and mix. Pour the melted and medicated basis upon a sheet of plate glass 10 centimetres square, previously thinly coated with White Beeswax, in such a manner that the solution is evenly distributed. Dry at a temperature not exceeding 36° C. (96.8° F.), and from the film thus obtained cut discs 3 millimetres (nearly ⅛ inch) in diameter."

LAMELLÆ ATROPINÆ. Br.

DISCS OF ATROPINE

(lą-mĕl'læ ăt-rǫ-pī'næ)

Disques d'Atropine, *Fr.*; Atropinplättchen, *G.*

"Discs of Atropine are discs of Gelatin with Glycerin, each weighing about 1.3 milligrams (1/50 grain) and containing 0.013 milligram (1/5000 grain) of Atropine Sulphate. Prepare as directed in Appendix X, employing 0.016 gramme of Atropine Sulphate and 8.8 grammes of *basis*." *Br.*

LAMELLÆ COCAINÆ. Br.

DISCS OF COCAINE

(lą-mĕl'læ cō-cą-ī'næ)

Disques de Cocaine, *Fr.*; Cocainplättchen, *G.*

"Discs of Cocaine are discs of Gelatin with Glycerin, each weighing about 3.5 milligrams (1/20 grain) and containing 1.3 milligrams (1/50 grain) of Cocaine Hydrochloride. Prepare as directed in Appendix X, employing 1.65 grammes of Cocaine Hydrochloride and 15 grammes of *basis*." *Br.*

LAMELLÆ HOMATROPINÆ. Br.

DISCS OF HOMATROPINE

(lą-mĕl'læ hō-măt-rǫ-pī'næ)

Disques d'Homatropine, *Fr.*; Homatropinplättchen, *G.*

"Discs of Homatropine are discs of Gelatin with Glycerin, each weighing about 2.1 milligrams (1/32 grain) and containing 0.65 milligram (1/100 grain) of Homatropine Hydrobromide. Prepare as directed in Appendix X, employing 0.82 gramme of Homatropine Hydrobromide and 10.1 grammes of *basis*." *Br.*

Lucas (*C. D.*, 1899, 959) furnishes an improved formula for these discs; it is as follows: Gelatin, 30 gr.; Glycerin, 3 gr.; Distilled Water, 150 gr.; Homatropine hydrobromide, 10 gr. Dissolve and pour on to a waxed plate, so as to produce a film exactly 4 inches square. When dry, but still supple, punch out discs 1-7 inch diameter.

The product is about 784 discs, the remainder of the film being wasted. Each disc will weigh rather less than 1-20 gr. No inconvenience has been found in using discs weighing 1-15 gr., as, owing to their extreme tenuity, they soften as soon as they are inserted beneath the eyelid.

LAMELLÆ PHYSOSTIGMINÆ. Br.

DISCS OF PHYSOSTIGMINE [Discs of Eserine]

(lą-mĕl'læ phȳ-sǫ-stĭg-mī'næ)

Disques d'Ésérine, *Fr.*; Physostigminplättchen, *G.*

"Discs of Physostigmine are discs of Gelatin with Glycerin, each weighing about 1.3 milligrams (1/50 grain) and containing 0.065 milligram (1/1000 grain) of Physostigmine Sulphate. Prepare as directed in Appendix X, employing 0.082 gramme of Physostigmine Sulphate and 8.45 grammes of *basis*." *Br.*

LAUROCERASI FOLIA. Br.

CHERRY-LAUREL LEAVES

(lâų'rō-cĕr'ą-sī fō'lĭ-ą)

"Cherry-Laurel Leaves are the fresh leaves of Prunus Laurocerasus, *Linn.*" *Br.*

Cherry Bay; Laurier-cerise, *Fr. Cod.*; Kirschlorbeer, *G.*; Lauroceraso, *It.*; Laurel-cerezo (Hoja de), *Sp.*

Prunus Laurocerasus is a small evergreen tree, rising 15 or 20 feet, with long, spreading branches, which, as well as the trunk, are covered with a smooth, blackish bark. The leaves are oval-oblong, petiolate, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit is an oval drupe, very similar in shape and structure to a small black cherry. The cherry-laurel is a native of Asia Minor, but is cultivated in Europe, both for medicinal use and for the beauty of its shining evergreen foliage. Almost all parts of it have more or less of the odor of hydrocyanic acid.

In their recent and entire state cherry-laurel leaves have scarcely any odor; but, when bruised, they emit the characteristic odor of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the flavor of the peach kernel. They are officially described as "thick, coriaceous, on short, strong petioles, oblong or somewhat obovate, from twelve to eighteen centimetres long, tapering towards each end, recurved at the apex, distantly but sharply serrate and slightly revolute at the margins; dark green, smooth and shining above, much paler beneath; midrib prominent, with one or two glandular depressions on the under surface near its base. Inodorous, but emitting when bruised an odor resembling that of prussic acid." *Br.*

Cherry-laurel leaves are sometimes substituted by the leaves of other species of *Prunus*. These are readily distinguished in that they do not possess the characteristic glandular hairs which occur on the basal portion of the leaves and petioles of *P. Laurocerasus*. (*B. P. G.*, 1907, p. 325.)

Cherry-laurel leaves yield a volatile oil containing benzaldehyde and hydrocyanic acid by distillation with water, which they strongly impregnate with their flavor. One pound, avoirdupois, of the fresh leaves yields 40.5 grains of the oil. (*Ph. Cb.*, 1855, 205.) The oil resembles that of bitter almonds, for which it is said to be sometimes sold in Europe, where it is employed to flavor liquors and various culinary preparations, but, as the glucoside of cherry-laurel leaves is decomposed more slowly than ordinary crystallized amygdalin, it is liable to hold hydrocyanic acid, and hence to be poisonous. The glucoside referred to has been termed *laurocerasin*, or "amorphous amygdalin." It is decomposed by emulsin into hydrogen cyanide, benzaldehyde, and sugar, but more slowly

than ordinary amygdalin. Its optical activity also differs from that of ordinary amygdalin. (Jacobsen, *Die Glykoside,* 25.) That the oil exists already formed, to a certain extent, in the fresh leaves, is rendered probable by the fact, stated by Winckler, that they yield it in considerable quantity when distilled without water. (*J. P. C.,* xxv, 195.) The fresh leaves are used to flavor milk, cream, etc., and more safely than the oil, though they also are poisonous, when too largely employed.

Uses.—The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid, and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it deteriorates by age, and therefore, as kept by pharmacists, must be of variable strength. J. Bröker, a Dutch pharmacologist, has satisfied himself, by numerous experiments, that the proportion of hydrocyanic acid in the leaves varies with the season, the age of the plant, the character of the soil and of the weather, and thinks that, in consequence of this variability, they are inferior for medicinal use to bitter almonds, which in this respect have a more uniform composition. He found the proportion of the acid in the leaves greatest in July, and least in February. (*B. F. M. R.,* Oct., 1868, p. 517.) It is not, therefore, to be regretted that the want of the plant in this country has prevented the general introduction of so variable a remedy as the distilled water. (See *Aqua Laurocerasi.*)

Off. Prep.—Aqua Laurocerasi, *Br.*

LIMONIS CORTEX. U. S., Br.

LEMON PEEL Limon. Cort.

(lĭ-mō'nĭs cŏr'tĕx)

"The outer rind of the fresh ripe fruit of *Citrus medica Limonum* (Risso) Hooker filius (Fam. *Rutaceæ*)." *U. S.* "Lemon Peel is the fresh outer part of the pericarp of the fruit of Citrus medica, *Linn.,* var. β Limonum, *Hook. f.*" *Br.*

Limonis Pericarpium; Ecorce (Zeste) de Citron, de Limon, *Fr. Cod.;* Cortex Citri Fructus, *P. G.;* Citronenschale, Limonenschale *G.;* Scorza di Limone, *It.*

For some general remarks on the genus *Citrus,* see *Aurantii Cortex.*

Citrus medica, or lemon tree, closely resembles *Citrus Aurantium,* before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is different in appearance from the orange. There are several varieties of *Citrus medica,* which some botanists consider as distinct species, but which scarcely differ except in the character of their fruits. Those particularly deserving of notice are the citron, lemon, and lime. 1. In the *citron, C. medica genuina* (*Bentley & Trimen,* p. 53), the fruit is very large, sometimes six inches in length, ovoid, with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick and spongy. It is divided in the interior into nine or ten loculi, filled with small oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves to which it is adapted by its thickness. The fruit is called *cédrat* by the French. 2. The *lemon, C. medica,* var. *Limonum* (*Citrus Limonum* of Risso) (*Bentley & Trimen,* p. 54) is smaller than the preceding, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy, acid pulp. In other respects it closely resembles the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. 3. The *lime* is still smaller than the lemon, with a smoother and thinner rind, oval, rounded at the extremities, of a pale-yellow or greenish-yellow color, and abounding in a very acid juice, which renders it highly useful for the purposes to which the lemon is applied. It is the product of *C. medica acida.* According to E. M. Holmes the West India limes are much richer in acid than are those produced in the South of Europe; the juice of the spineless variety was found to contain 37.73 grains per ounce; the ordinary West India lime 36.15 grains per ounce; the Sicily lime 30.32 grains per ounce. Lime juice is recognized by the N. F. IV under the name *Succus Citri.*

The *Citrus medica,* like the orange-tree, is a native of Asia. It is now known to grow wild in Northern India, and was introduced into Europe from Persia or Media. It was first cultivated in Greece, afterwards in Italy, as early as the second century, and has now spread over the whole civilized world, being raised by artificial heat where the climate is too cold to admit of its exposure during winter to the open air.

Properties.—The exterior rind of the lemon has a fragrant odor, and a warm, aromatic bitter taste, somewhat similar to that of the orange, though less agreeable. It is usually found in narrow, thin bands, with very little of the spongy, white, inner layer adhering to it, and is officially described as follows: "The outer, lemon-yellow or dark yellow layer, recently separated by grating or paring and consisting of an epidermal layer, numerous parenchyma cells containing yellow chromoplastids, and large oil reservoirs with globules of the volatile oil; odor highly fragrant, distinctive; taste pungent, aromatic. Under the microscope, sections of the rind, mounted in a fixed oil, show an epidermal layer composed of small tabular cells, a hypodermal layer containing numerous plastids, a mesocarp with colorless, thin-walled parenchyma and large, elliptical oil reservoirs; parenchyma cells containing a layer of granular protoplasm adhering to the walls and occasionally membrane crystals of calcium oxalate,

which are irregularly polygonal in shape, and from 0.015 to 0.025 mm. in diameter." *U. S.*

"Outer surface pale yellow and more or less rough; with only a small amount of the white spongy part of the pericarp on the inner surface; in transverse section numerous large oil-glands below the epidermis. Strong, characteristic and fragrant odor; taste aromatic and bitter." *Br.*

It contains a bitter principle, and yields, by expression or distillation, an essential oil, which is much used for its flavor. Both this and the rind itself are recognized in the Pharmacopœias. (See *Oleum Limonis.*) When the white, spongy portion of the rind is boiled in water, and the decoction evaporated, crystals are deposited of a substance called *hesperidin.* This is a glucoside, and has the formula $C_{22}H_{26}O_{12}$, and is decomposed by diluted acids into *hesperetin,* $C_{16}H_{14}O_6$, and glucose, $C_6H_{12}O_6$. It turns dingy black when gently warmed with alcoholic solution of ferric chloride. It is bitter, but as it is found most largely in the spongy and comparatively tasteless part of the rind, it may be doubted whether it is entitled to be considered as the active bitter principle. (See *A. J. P.,* xxvi, 553.) Lemon peel yields its virtues to water, wine, and alcohol. E. G. Clayton (*An.,* xix, 134) calls attention to the distinction between lemon peel and orange peel when moistened by strong hydrochloric acid. Orange peel under these circumstances changes in color from a yellow to a rich dark green color, while lemon peel retains its hue or assumes a dingy yellowish-brown tint.

The German Pharmacopœia under the title of *Cortex Citri Fructus* requires that the lemon peel be derived from the completely developed but not fully ripe fruits of *Citrus medica* L.

Uses.—The rind of the lemon is sometimes used to qualify the taste and increase the power of stomachic infusions and tinctures.

Off. Prep.—Tinctura Limonis Corticis, *U. S.* (*Br.*); Infusum Aurantii Compositum, *Br.;* Syrupus Limonis, *Br.*

LINIMENTA

LINIMENTS

(lĭn-ĭ-mĕn'tą)

Embrocations; Liniments, Embrocations, *Fr.;* Linimenta, Linimente, Einreibungen, *G.*

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand.

LINIMENTUM ACONITI. Br.

LINIMENT OF ACONITE

(lĭn-ĭ-mĕn'tŭm ăc-ǫ-nī'tī)

"Liniment of Aconite contains in 100 millilitres 0.2 gramme of the ether-soluble alkaloids of Aconite Root." *Br.*

Liniment d'Aconit, *Fr.;* Akonitliniment, *G.*

"Aconite Root, in No. 40 powder, 500 *grammes;* Camphor, Alcohol (90 per cent.), of each, *a sufficient quantity.* Moisten the Aconite Root with part of the Alcohol, pack in a percolator, and percolate with more of the Alcohol until the Root is exhausted. Reserve the first seven hundred and fifty *millilitres* of the percolate; evaporate the remainder to a syrup and add it to the reserved portion. Determine the weight of ether-soluble alkaloids in fifteen *millilitres* of the tincture thus obtained by the process described under 'Aconiti Radix.' Add to the remainder of the tincture sufficient of the Camphor and of the Alcohol to produce a Liniment of Aconite containing in 100 millilitres 0.2 gramme of the ether-soluble alkaloids of Aconite Root and 3 grammes of Camphor. Examined by the foregoing process Liniment of Aconite is found to contain in 100 *millilitres* 0.2 gramme of the ether-soluble alkaloids of Aconite Root. *Limit of error* 0.01 gramme in excess or defect." *Br.*

This preparation of the British Pharm., 1914, is now made of a definite strength through the introduction of an assay process. It is a very strong tincture of aconite root with camphor; that of the U. S. P., 1870, was almost equivalent to a fluidextract of aconite.

Uses.—Either may be applied alone by means of a camel's-hair pencil, or in connection with two parts or more of soap liniment or chloroform liniment, by rubbing it on the part affected. It must be used with caution lest sufficient aconite be absorbed through the skin to cause poisoning.

(lĭn-ĭ-mĕn'tŭm ąm-mō'nī-æ)

Liniment of Ammonia, Linimentum volatile, Linimentum ammoniacale; Liniment ammoniacal (volatil), *Fr. Cod.;* Savon ammoniacal, *Fr.;* Linimentum Ammoniatum, *P. G.;* Flüchtiges Liniment, Flüchtige Salbe, *G.;* Linimento ammoniacale, *It.;* Linimento amoniacal, *Sp.*

* "Ammonia Water, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Sesame Oil, *seven hundred and fifty mils* [or 25 fluidounces, 173 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Agitate the ammonia water with the sesame oil until a uniform mixture is obtained." *U. S.*

"Solution of Ammonia, 250 *millilitres;* Almond Oil, 250 *millilitres;* Olive Oil, 500 *millilitres.* Shake together." *Br.*

The process of the U. S. Pharmacopœia IX differs from that of the U. S. P. VIII not only in the proportion of ammonia water, which has been slightly reduced, but in the substitution of sesame oil for cottonseed oil. The British preparation is made with almond oil and olive oil with the proviso that "in India, and in the Eastern, African, Australasian, and North American Divisions of the Empire, Arachis Oil or Sesame Oil, but no other oil or fat, may be employed in making the official

Liniments, Plasters, Ointments, and Soaps for which Olive Oil is directed to be used." *Br.*

The U. S. and British Pharmacopœias agree at present very nearly in the strength of this liniment. In the process, the ammonia reacts with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, with the added advantage of being relatively inexpensive, in *inflammatory affections of the throat,* in *catarrhal and other pectoral complaints of children,* and in *rheumatic pains.* It is applied by rubbing it, or placing a piece of flannel saturated with it, over the affected part. Should it occasion too much inflammation, it must be diluted with oil.

LINIMENTUM BELLADONNÆ. U. S., Br.

BELLADONNA LINIMENT Lin. Bellad.

(lĭn-ĭ-mĕn'tŭm bĕl-la-dŏn'næ)

Liniment of Belladonna; Liniment de Belladone, *Fr.;* Belladonnaliniment, *G.*

* " Camphor, *fifty grammes* [or 1 ounce av., 334 grains]; Fluidextract of Belladonna Root, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Camphor in about *eight hundred mils* [or 27 fluidounces, 24 minims] of the Fluidextract, and then add enough of the latter to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

" Liquid Extract of Belladonna, 500 *millilitres;* Camphor, 50 *grammes;* Distilled Water, 100 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Camphor in three hundred *millilitres* of the Alcohol; add the Liquid Extract of Belladonna, the Distilled Water, and sufficient of the Alcohol to produce the required volume. Set aside for twenty-four hours; filter." *Br.*

The two liniments are not identical in strength. The U. S. P. fluidextract of belladonna representing in 100 mils 0.45 Gm. of mydriatic alkaloids, while the British Pharm., 1914, requires liquid extract of belladonna to contain 0.75 Gm. of mydriatic alkaloids; but it will be observed that in the British liniment the liquid extract of belladonna is diluted with alcohol and water, so that the difference in strength will not be important for a preparation to be used externally.

The process for this liniment in both Pharmacopœias has been improved by using an assayed fluidextract.

LINIMENTUM CALCIS. U. S., Br.

LIME LINIMENT Lin. Calc. [Carron Oil]

(lĭn-ĭ-mĕn'tŭm căl'cĭs)

Liniment of Lime; Liniment calcaire, *Fr. Cod.;* Savon calcaire, *Fr.;* Kalkliniment, *G.;* Linimento de calce, *It.;* Linimento Oleo-calcareo, *Sp.*

* " Solution of Calcium Hydroxide, *five hundred mils* [or 16 fluidounces, 435 minims]; Linseed Oil, *five hundred mils* [or 16 fluidounces, 435 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix them by agitation." *U. S.*

" Solution of Lime, 500 *millilitres;* Olive Oil, 500 *millilitres.* Shake together." *Br.*

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the British Pharmacopœia, is often substituted for that of flaxseed, which was originally used, but it possesses no other advantage than that of having a less unpleasant odor and of being somewhat less expensive. The use of cottonseed oil in the U. S. P., 1880, did not meet the expectations of those who proposed it, and the U. S. P., 1890, reinstated linseed oil. This is a very useful application in recent *burns* and *scalds,* when smeared thickly upon lint or cotton batting. It is sometimes called *Carron oil,* from having been much employed at the Carron iron works in Scotland. It relieves the pain by excluding the air and restoring alkalinity in the burnt area.

LINIMENTUM CAMPHORÆ. U. S., Br.

CAMPHOR LINIMENT Lin. Camph. [Camphorated Oil]

(lĭn-ĭ-mĕn'tŭm căm'phŏ-ræ)

" *One hundred grammes* of Liniment of Camphor yields not less than 19.5 Gm. nor more than 20.5 Gm. of Camphor. This preparation is not intended for hypodermic use." *U. S.*

Liniment of Camphor, Linimentum Camphoratum; Huile camphrée, *Fr. Cod.;* Liniment camphré, *Fr.;* Kampherliniment, Kampheröl, *G.*

* " Camphor, in coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Cottonseed Oil, *eight hundred grammes* [or 28 ounces av., 96 grains], to make *one thousand grammes* [or about two pints]. Introduce the cottonseed oil into a suitable flask or bottle, heat it on a water bath, introduce the camphor and stopper the container securely. Dissolve the camphor by agitation without the further application of heat.

" **Assay.**—Weigh 25 Gm. of Camphor Liniment into a tared 150 mil flask and connect this flask with a 500 mil distillation flask containing 275 mils of alcohol. Adjust the tube from the distillation flask so that it reaches to within 0.5 cm. of the bottom of the flask containing the Liniment and connect the latter flask with a condenser. Now heat both flasks on sand baths and regulate the temperature so that the alcohol vapors will pass rapidly through the Liniment without condensing. Receive the distillate in a flask graduated to 250 mils and continue the distillation until at 25° C. (77° F.) the distillate measures 250 mils. Fill a 200 mm. polariscope tube with the distillate and take the mean of four or more readings of the rotation, beginning at zero each time. The temperature correction for each degree is half a minute, additive if above, subtractive if below

25° C. (77° F.). Place about 20 Gm. of the Camphor Liniment in an evaporating dish, 9 cm. in diameter, and cover it with an inverted funnel 8 cm. in diameter. Place the dish on wire gauze, 10 cm. above a Bunsen burner having a flame 4 cm. high. When the camphor has all sublimed, dissolve 0.5 Gm. of the sublimate in sufficient alcohol to make exactly 25 mils at 25° C. (77° F.), and take the mean of four or more polariscope readings as before. The minutes of rotation of the distillate divided by the minutes of rotation of the control test just made, and this multiplied by 20, will give the number of grammes of camphor in 100 Gm. of Camphor Liniment." *U. S.*

"Camphor, in flowers, 200 *grammes;* Olive Oil, 800 *grammes.* Dissolve the Camphor in the Olive Oil in a closed vessel." *Br.*

S. D. Wetterstroem prefers cold solution to the official method, thus avoiding any loss of camphor. (*West. Drug.,* 1897, 68.) For methods of assaying camphor liniment, see *C. D.,* 1900, 338; *P. J.,* 1898, 545; *P. J.,* 1902, 106; *Am. Drug.,* 1905, 345.

Uses.—This liniment is a very popular counter-irritant embrocation in *sprains, bruises, rheumatism, acute bronchitis,* and various other inflammatory states. Camphor liniment should not be confounded with camphorated oil of the German Pharmacopœia which is much weaker (1 in 10).

For fatal case of poisoning from swallowing this liniment, see Barker, *B. M. J.,* 1910, ii, p. 921.

The term "camphorated oil" is sometimes applied to the solution of camphor in olive oil intended for hypodermic use; the liniment of camphor must not be used for this purpose.

Off. Prep.—Linimentum Chloroformi, *Br.;* Linimentum Hydrargyri, *Br.;* Linimentum Terebinthinæ Aceticum, *Br.;* Ceratum Camphoræ, *N. F.*

LINIMENTUM CAMPHORÆ AMMONIATUM. Br.

AMMONIATED LINIMENT OF CAMPHOR

(lĭn-ĭ-mĕn'tŭm căm'phŏ-ræ ăm-mŏ-nī'ă-tŭm)

Compound Liniment of Camphor, *Br.;* Liniment ammoniacal camphré, *Fr. Cod.;* Linimentum ammoniato-camphoratum, *P. G.;* Flüchtiges Kampherliniment, Ammoniak- und Kampher-Liniment, *G.;* Linimento ammoniacale canforato, *It.;* Linimento amoniacal alcanforado, *Sp.*

"Camphor, 125 *grammes;* Oil of Lavender, 5 *millilitres;* Strong Solution of Ammonia, 250 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Camphor and Oil of Lavender in six hundred *millilitres* of the Alcohol; add the Strong Solution of Ammonia gradually, shaking frequently; finally add sufficient of the Alcohol to produce the required volume." *Br.*

This is inferior to the camphor liniment because the absence of a lubricant makes rubbing difficult.

LINIMENTUM CHLOROFORMI. U. S., Br.

CHLOROFORM LINIMENT Lin. Chlorof.

(lĭn-ĭ-mĕn'tŭm ȼhlō-rŏ-fōr'mī)

Liniment of Chloroform; Liniment au Chloroforme, *Fr. Cod.;* Chloroformliniment, *G.*

* "Chloroform, *three hundred mils* [or 10 fluidounces, 69 minims]; Soap Liniment, *seven hundred mils* [or 23 fluidounces, 321 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix them by agitation." *U. S.*

"Chloroform, 500 *millilitres;* Liniment of Camphor, 500 *millilitres.* Mix." *Br.*

A very great improvement was made in this preparation by the Committee of Revision of 1880, in the substitution of soap liniment for the olive oil. This change had been proposed in a previous edition of the Dispensatory, and it was desirable on account of the greasy residue which was left on the skin by the old preparation. The British Pharmacopœia has retained the oily vehicle. This is an excellent local application in painful affections. As the chloroform rapidly evaporates, it is desirable, in order to obtain its full counter-irritant effect, to guard against this by using waxed paper, or some other impermeable covering.

An accurate and expeditious method of assaying this liniment for its chloroform content is suggested by Jos. L. Mayer (*Proc. N. Y. S. P. Assn.,* 1912, p. 295), which consists in distilling the chloroform and collecting it in a graduated cylinder containing distilled water. The chloroform is measured when it ceases to come over and the calculation readily made.

LINIMENTUM CROTONIS. Br.

LINIMENT OF CROTON OIL

(lĭn-ĭ-mĕn'tŭm crŏ-tō'nĭs)

Linimentum Tiglii, *N. F. IV;* Liniment crotoné, *Fr.;* Krotonölliniment, *G.*

"Croton Oil, 120 *millilitres;* Oil of Cajuput, 440 *millilitres;* Alcohol (90 per cent.), 440 *millilitres.* Mix." *Br.*

This liniment is slightly weaker than that of the former British Pharmacopœia, but is almost identical with *Linimentum Tiglii* of N. F. IV (see Part III).

This is a pustulating preparation, the irritant influence of which has been increased by the substitution of the oil of cajuput and alcohol for the olive oil of the original formula. From ten to thirty minims (0.6–1.8 mils) may be rubbed upon a limited surface, and repeated twice a day or oftener until an eruption is produced.

LINIMENTUM HYDRARGYRI. Br.

LINIMENT OF MERCURY

(lĭn-ĭ-mĕn'tŭm hȳ-drăr'gy-rī)

Linimentum Mercuriale; Liniment mercuriel, *Fr.;* Quecksilberliniment, *G.*

"Ointment of Mercury, 50 *grammes;* Solution of Ammonia, 40 *millilitres;* Liniment of Camphor, 80 *millilitres.* Shake the Solution of Ammonia with the Liniment of Camphor, and

triturate the Ointment of Mercury with the mixture. This Liniment contains approximately three-fifths of the proportion of Mercury contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This is a stimulating liniment, employed for both its local and constitutional effects in *syphilitic pains,* in *glandular enlargements, swellings of the joints,* and to promote the absorption of fluid. It is said to be more likely to salivate than is mercurial ointment. One fluidrachm (3.75 mils) may be rubbed upon the affected part night and morning. It should be thoroughly agitated before being applied.

LINIMENTUM OPII. Br.

LINIMENT OF OPIUM

(lĭn-ĭ-mĕn'tŭm ō'pĭ-ī)

Anodyne Liniment; Liniment opiacé, *Fr.;* Opiumliniment, *G.*

"Tincture of Opium, 500 *millilitres;* Liniment of Soap, 500 *millilitres.* Mix; set aside for a few days; filter." *Br.*

We are informed that the preparation which has been commonly used under the name of *anodyne liniment* is that of the late London Pharmacopœia, as given in former editions of the *U. S. Dispensatory,* consisting of one part by measure of tincture of opium and three parts of soap liniment, and consequently having only half the opiate strength of the present British liniment. The use of this class of preparations is founded on error, as opium is not efficient as a local remedy.

LINIMENTUM POTASSII IODIDI CUM SAPONE. Br.

LINIMENT OF POTASSIUM IODIDE WITH SOAP

(lĭn-ĭ-mĕn'tŭm pŏ-tăs'sĭ-ī ī-ŏd'ĭ-dī cŭm sā-pō'nē)

Liniment savonneux ioduré, *Fr.;* Jodkalium-Seifenliniment, *G.*

"Curd Soap, recently prepared and in shavings, 40 *grammes;* Potassium Iodide, 30 *grammes;* Glycerin, 20 *millilitres;* Oil of Lemon, 2 *millilitres;* Distilled Water, 200 *millilitres.* Mix the Curd Soap with the Distilled Water and Glycerin in a tared porcelain dish on a water-bath; when the Soap is dissolved make up to the original weight with Distilled Water; pour the liquid into a mortar containing the Potassium Iodide, previously powdered; mix briskly by trituration; continue the trituration until the mixture is cold, set aside for an hour; then add the Oil of Lemon, and again triturate the gelatinous product." *Br.*

This preparation is apparently intended, by application to the surface, which may be attended with a gentle friction, to produce the absorption of the iodide, and thus to obtain its alterative and deobstruent effects through the circulation. The soap and glycerin act as demulcents, and thus obviate in some measure the local irritation of the salt.

LINIMENTUM SAPONIS. U. S., Br.

SOAP LINIMENT Lin. Sapon. [Liquid Opodeldoc]

(lĭn-ĭ-mĕn'tŭm sā-pō'nĭs)

Tinctura Saponis Camphorata, *U. S.* 1850; Spiritus Nervinus Camphoratus; Camphorated Tincture of Soap; Liniment savonneux camphré, *Fr.;* Linimentum saponato camphoratum, *P. G.;* Flüssiger Opodeldok, *G.;* Linimento di sapone con canfora, *It.*

* "Soap, dried and granulated or powdered, *sixty grammes* [or 2 ounces av., 51 grains]; Camphor, in small pieces, *forty-five grammes* [or 1 ounce av., 257 grains]; Oil of Rosemary, *ten mils* [or 162 minims]; Alcohol, *seven hundred mils* [or 23 fluidounces, 321 minims]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the camphor and the oil of rosemary in the alcohol, add the soap and sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Agitate the mixture until the soap is dissolved, set it aside in a cool place for twenty-four hours, and then filter." *U. S.*

"Soft Soap, 80 *grammes;* Camphor, 40 *grammes;* Oil of Rosemary, 15 *millilitres;* Distilled Water, 170 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Soap, Camphor, and Oil of Rosemary in six hundred *millilitres* of the Alcohol; add the Distilled Water and sufficient of the Alcohol to produce the required volume; set aside for a week; filter." *Br.*

This process is intended to furnish a saturated solution of Castile soap. The recommendation in the 16th edition of this Dispensatory, that granulated soap be used in preference to soap in shavings in this liniment, was adopted by the U. S. Pharmacopœia, Eighth Revision, for powdered soap does not vary greatly in the proportion of water left in it; the process is one recommended by Geo. W. Sloan, of Indianapolis, and if all the details are carefully followed it is a great improvement over that of the U. S. Pharmacopœia 1880. The improvement was made in the eighth revision of the U. S. P. of making a gelatinous mass of the soap by adding it to sufficient boiling water and heating it until dissolved; the soft mass easily dissolves in the alcoholic solution of the oils, but in the U. S. P. IX process the granulated or powdered soap is added to the alcohol and when the water is introduced solution occurs almost at once. The liquid should be cold before filtration to avoid precipitation in cold weather. The British preparation is now made with soft (potash) soap; this method was recommended by J. T. Hornblower. (*C. D.,* 1894, 571.) The liniment is said to be made more quickly and precipitation is avoided. Although olive oil contains a large percentage of olein, yet it has been proposed to substitute almond oil, for it is still richer. A formula for making almond oil soap on the small scale may be found in *P. J.,* 2d ser., xi, 417. The economy of this is, however, very doubtful. Castor oil has also been suggested. (*A. J. P.,* xliv, 529.) G. W. Barckhausen states that the potassa soaps are per-

fectly soluble in alcohol, and suggests rape seed oil as a good base. (*A. J. P.*, 1873, p. 17.)

Any pharmaceutical difficulty encountered in making a satisfactory preparation by the official formula can usually be attributed to the use of soap which is not in compliance with the official requirements.

The 1850 edition of the U. S. Pharmacopœia recognized under the title *Linimentum Saponis Camphoratum* a semi-solid preparation which had a wide popularity under the name *opodeldoc.* (See *N. F.*, Part III.) Older formulas for this preparation are well represented by the U. S. P., 1850, process as follows:

Opodeldoc.—"Take of Common Soap (made from animal oil), sliced, *three ounces;* Camphor *an ounce;* Oil of Rosemary, Oil of Origanum, each, *a fluidrachm;* Alcohol *a pint.* Digest the Soap with the Alcohol, by means of a sand-bath, till dissolved; then add the Camphor and Oils, and, when they are dissolved, pour the liquid into broad-mouthed bottles. This liniment has, when cold, the consistence of a soft ointment." *U. S. P.*, 1850.

This preparation differs from the official Linimentum Saponis chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made of olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary after the solution of the soap has been effected to pour the liquid into small wide-mouthed glass bottles, containing about four fluidounces, in which it concretes into a soft, translucent, uniform, yellowish-white mass. This liniment melts with the heat of the body.

Soap liniment is much used, as an anodyne and gently rubefacient embrocation, in *sprains, bruises,* and *rheumatic* or *gouty pains.*

Off. Prep.—Linimentum Chloroformi, *U. S.;* Linimentum Opii, *Br.;* Linimentum Aconiti et Chloroformi, *N. F.*

LINIMENTUM SAPONIS MOLLIS. U. S.

LINIMENT OF SOFT SOAP Lin. Sapon. Moll. [Tincture of Green Soap]

(lĭn-ĭ-mĕn'tŭm sā-pō'nĭs mŏl'lĭs)

Tinctura Saponis Virdis, *U. S. P.* 1880; Spiritus Saponis Kalini Hebra; Teinture de Savon vert, *Fr.;* Hebra's Seifenspiritus, *G.*

* "Soft Soap, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Oil of Lavender, *twenty mils* [or 325 minims]; Alcohol, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the oil of lavender with *three hundred mils* [or 10 fluidounces, 69 minims] of alcohol, dissolve in this the soft soap by stirring or agitation, and set the solution aside for twenty-four hours. Then filter it through paper, adding sufficient alcohol to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is the *tincture of green soap* of Hebra under a new name; it should never have been called Tinctura Saponis Viridis, as it belongs clearly in the class of liniments and is always used externally. C. E. Smith suggested the preparation of this liniment from the fixed oil directly, which has the advantage of convenience as well as of greater uniformity of strength. (See *U. S. D.*, 19th ed., p. 698.) If a green color is desirable in this preparation, it may be obtained by using hemp seed oil or Malaga olive oil. (See *Proc. A. Ph. A.*, 1903, 420.)

LINIMENTUM SINAPIS. Br.

LINIMENT OF MUSTARD

(lĭn-ĭ-mĕn'tŭm sĭ-nā'pĭs)

Linimentum Sinapis Compositus, *N. F.;* Liniment Sinapisé composé, *Fr.;* Zusammengesetztes Senfliniment, Senfliniment, *G.*

"Volatile Oil of Mustard, 35 *millilitres;* Camphor, 55 *grammes;* Castor Oil, 125 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Camphor and the Oils in the Alcohol." *Br.*

The N. F. preparation differs from the Br. in containing fluidextract of mezereum in addition to the mustard oil and camphor (see Part III). It affords a convenient method of applying the volatile oil of mustard, and may often be appropriately used as a substitute for sinapisms. The castor oil seems to be added in order to increase somewhat the consistence of the liniment, and was probably chosen from among oleaginous substances in consequence of its solubility in alcohol. The effect is increased if the liniment be applied on flannel, and volatilization guarded against by covering it with oiled silk.

LINIMENTUM TEREBINTHINÆ. U. S., Br.

TURPENTINE LINIMENT Lin. Terebinth. [Kentish's Ointment]

(lĭn-ĭ-mĕn'tŭm tĕr-ĕ-bĭn'thĭ-næ)

Linimentum Terebinthinatum; Liniment of Turpentine; Liniment térébenthiné, *Fr.;* Terpentinliniment, *G.*

* "Rosin Cerate, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Oil of Turpentine, *three hundred and fifty grammes* [or 12 ounces av., 151 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the Rosin Cerate, previously melted in a dish on a water-bath, in the Oil of Turpentine, and mix them thoroughly." *U. S.*

"Soft Soap, 75 *grammes;* Camphor, 50 *grammes;* Rectified Oil of Turpentine, 650 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Mix the Soft Soap with one hundred *millilitres* of the Distilled Water; dissolve the Camphor in the Oil of Turpentine; gradually add the latter solution to the former, triturating until the mixture becomes a thick creamy emulsion; add sufficient Distilled Water to produce the required volume." *Br.*

The U. S. preparation is the liniment originally proposed by Kentish, and subsequently so highly lauded as a remedy in *burns* and *scalds.* It should be applied as soon after the occurrence of the accident as possible, and

should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burnt or scalded surface with pledgets of gauze saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of *erysipelas*. The present British preparation, so far as regards its rubefacient operation, may be looked upon as almost undiluted oil of turpentine, the soft soap having little other effect than to give consistence to the liniment, and the camphor acting as an anodyne, and both being too small in bulk to dilute the oil materially.

LINIMENTUM TEREBINTHINÆ ACETICUM. Br.

LINIMENT OF TURPENTINE AND ACETIC ACID

(lĭn-ĭ-mĕn'tŭm tĕr-ĕ-bĭn'thĭ-næ ą-cĕt'ĭ-cŭm)

Linimentum Album; Acetic Turpentine Liniment, Stokes' Liniment; Liniment térébenthiné acétique, *Fr.*; Terpentin- und Essig-liniment, *G.*

"Glacial Acetic Acid, 110 *millilitres;* Liniment of Camphor, 445 *millilitres;* Rectified Oil of Turpentine sufficient to produce 1000 *millilitres.* Mix." *Br.*

Under this name the National Formulary IV (see Part III) contains a formula for *St. John Long's Liniment,* which unfortunately is not identical with the process of the British Pharm., 1914.

This is a powerful rubefacient liniment, combining the irritant properties of the oil of turpentine and acetic acid, though somewhat diluted by the camphor liniment. Glacial acetic acid was substituted for acetic acid in the 1885 revision in equivalent proportion; the change is an improvement pharmaceutically, as it now affords a clear solution.

LINUM. U. S. (Br.)

LINSEED [Flaxseed]

(lī'nŭm)

"The ripe seeds of *Linum usitatissimum* Linné (Fam. *Linaceæ*), without the presence or admixture of more than 3 per cent. of other seeds or foreign matter. Preserve it in tightly-closed containers and add a few drops of carbon tetrachloride or chloroform from time to time to prevent attack by insects." *U. S.* "Linseed consists of the dried ripe seeds of Linum usitatissimum, *Linn.*" *Br.*

Lini Semina, *Br.;* Semence de Lin, *Fr. Cod.;* Grains de Lin, *Fr.;* Semen Lini, *P. G.;* Leinsamen, Flachssamen, *G.;* Lino, Semi di Lino, *It.;* Lino (Semilla de), Linaza, *Sp.*

Off. Prep.—Lini Semina Contusa, *Br.;* Species Emollientes, *N. F.*

LINI SEMINA CONTUSA. Br.

CRUSHED LINSEED

(lī'nī sĕ-mī-ną cŏn-tū'są)

"Crushed Linseed is Linseed reduced to a coarse powder. It should be recently prepared." *Br.*

Linum Contusum, *Br.* 1898; Crushed Flaxseed.

Common *flax* is an annual plant, with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green color, sessile, and scattered alternately over the stem and branches. The flowers are terminal, and of a delicate-blue color. The calyx is persistent, and composed of five ovate, sharp-pointed, three-nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scalloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base, and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells. This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of Central Asia. It flowers in June and July, and ripens its seed in August.

The flax plant was cultivated for its fiber by the American colonists soon after the landing of Columbus. Soon thereafter it was grown for its seed and already in 1792 the United States exported nearly 300,000 bushels of flaxseed. Very early the linseed oil industry was developed in the United States and in 1810 there were nearly 300 linseed oil mills in the 14 states, more than half of them being in Pennsylvania. It is estimated that at the present time 12,000,000 bushels of seed are crushed annually for the oil. The annual crop of flaxseed in the United States approximates 30,000,000 bushels. A large quantity of seed is annually exported as well as oil-cake, the latter being extensively used as a cattle food.

Properties.—The official description of flaxseed is as follows: "Ovate or oblong-lanceolate, flattened, obliquely pointed at one end, from 3 to 5 mm. in length; externally chestnut-brown, very smooth and shiny, the raphe extending as a distinct, light-yellow ridge along one edge; easily cut with the finger-nail; internally olive-green; oily; odor slight; taste mucilaginous and oily. Under the microscope, transverse sections of Linseed when mounted in hydrated chloral T.S. show an epidermis with a mucilaginous layer from 0.01 to 0.03 mm. in thickness, covered by a very thin layer of cutin which is often more or less broken; two layers of parenchyma which overlie a continuous ring of stone cells having yellowish, porous walls and rather large lumina; a pigment layer, the cells having a reddish-brown content; an endosperm consisting of from 6 to 10 rows of cells surrounding the two large plano-convex cotyledons; the cells of both the endosperm and the cotyledons contain a fixed oil and aleurone grains, the latter being from 0.003 to 0.02 mm. in diameter." *U. S.*

"Seeds small, brown, glossy, nearly flat; from

about four to six millimetres long; ovate, somewhat obliquely pointed; surface glabrous and minutely pitted. Internally yellowish-white, with a narrow oily endosperm and two large oily cotyledons. Epidermal cells filled with mucilage which swells and dissolves in *water*. No odor; taste mucilaginous, oily." *Br.*

The linseeds in commerce have been divided by E. M. Holmes into two groups. The first group, characterized by the seeds being of sufficient size for six or seven to weigh a grain, contains Bombay, Bold Calcutta, Sicilian, and Ionian seed; in the group of small seeds (10 to 12 to the grain) are English, Dutch, Russian, and ordinary Calcutta varieties. An important practical point noticed by Holmes is that much of the drug of commerce is adulterated with weed seeds, which are nearly always smaller than the linseeds, and can therefore be separated by the sieve. When linseed meal is to be made for medicinal use, this separation should always be insisted upon, as many of the weed seeds are from Cruciferæ, and are irritating. For detailed information as to varieties of linseed, weed seeds, etc., the reader is referred to Holmes's paper. (*P. J.*, July, 1881; also *N. R.*, 1881.)

The ground seeds are found in commerce under the name of *flaxseed meal*. This is of a dark-gray color, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, much employed for luting by practical chemists. "The powder of flaxseed is lemon-yellow or light brown, consisting chiefly of large, oily globules and irregular fragments of endosperm and seed-coat; the seed-coat is characterized by the tabular pigment cells filled with a reddish-brown, insoluble content and the somewhat elongated stone cells with yellowish walls; mounts made from material from which the fixed oil has been removed show aleurone grains from 0.003 to 0.02 mm. in diameter, both free and in the cells of the endosperm and embryo. *Linseed Meal* or *Flaxseed Meal* is light olive-brown with reddish-brown fragments; the latter being very coarse and the cellular tissues are the same as those of the powder. Powdered Linseed or Flaxseed and Linseed Meal or Flaxseed Meal must be free from any unpleasant or rancid odor. The powder, upon extraction with purified petroleum benzin, yields not less than 30 per cent. of a fixed oil, at least 98 per cent. of which is saponifiable. Boil 1 Gm. of the fat-free Linseed or Flaxseed Powder or Meal, with 50 mils of water, cool and filter; the filtrate gives not more than a faint blue color, on the addition of iodine T.S. Linseed yields not more than 6 per cent. of ash." *U. S.*

Crushed flaxseed is "a coarse, brownish-yellow powder, with readily visible fragments of the brown seed-coats. Bland, not pungent or rancid, odor when mixed with warm *water*. Yields not less than 30 per cent. of oil when exhausted by *carbon disulphide;* the oil thus obtained responds to the tests described under 'Oleum Lini'; the residual powder exhibits no starch grains when examined under the microscope. Ash not more than 5 per cent." *Br.*

The average composition of linseed oil cake is thus given by Schaedler (*Technologie der Fette und Oele,* 1883): moisture, 10.56 per cent.; oil, 9.83 per cent.; non-nitrogenous fiber, 44.61 per cent.; ash, 6.5 per cent.; proteid matter, 28.5 per cent.

Much of the linseed meal of commerce is simply cake meal, which was, indeed, official in the former Br. Ph., but such meal is unfit for medicinal use, not only because it contains very little oil, but also because the oil which is in it has, through rupture of the cells and partial expression, been so exposed to the air as to become rancid. Linseed meal is sometimes adulterated with corn meal, or other meals containing starch, whose presence is at once revealed by the iodine test. It is sometimes found in the market adulterated with petroleum or other mineral oil, doubtless made by powerfully pressing the pure linseed meal and substituting for the linseed oil the less expensive product, petroleum. (*A. J. P.*, 1902, 31.)

The absolute value of a sample of crushed linseed can be determined by analysis. It should contain from 25 to 35 per cent. of oil, not more than 8 or 8.5 per cent. of husk, and less than 8 per cent. of ash. The following *test* is said to be sufficient for practical purposes: "Put half an ounce of the meal into a glass vessel, pour six ounces of boiling water over it, stir well, and allow it to stand for twelve hours. If first-class, it should absorb all the water, and show a thin scum of white glutinous liquid on the top, which will adhere closely to a glass rod or a wooden pencil dipped into it. If the meal does not absorb nearly all the water, it is of inferior quality. The amount of inferiority must be judged by the amount of water not absorbed, and by the character of the fluid on the top of the solution. If it is thin and non-glutinous, the meal is of inferior quality."

Meyer found in linseed fixed oil, wax, resin, extractive, tannin, gum, nitrogenous mucilage, starch, albumen, gluten, and various salts. Meurein could find no starch, but detected phosphates, which had escaped the notice of Meyer. (*J. P. C.*, 3e sér., xx, 97.) For some years there has been a discussion concerning the reaction for starch which is sometimes ascertained in commercial flaxseed. Apparently starch grains are not usually present, although it is stated that they may occur in appreciable quantities in the unripe seed. (*Ph. Ztg.*, li, p. 658.) Certain tissues of the seed coat beneath the mucilaginous epidermis may give a starch reaction, and it is stated that even the cells may contain starch. (*Proc. A. Ph. A.*, 1907, lv, p. 326.) Their investing coat abounds in a peculiar gummy matter or mucilage, which is readily imparted to hot water, forming a thick viscid fluid, that lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with lead subacetate. The viscid mucilage of linseed cannot be filtered until it has been boiled.

It contains in the dry state more than 10 per cent. of mineral substances; when freed from these and dried at 110° C. (230° F.), it has, like althæa mucilage, the formula $C_{12}H_{20}O_{10}$. The seeds by exhaustion with cold or warm water afford about 15 per cent. of this mucilage. By boiling with nitric acid, it yields crystals of mucic acid; by diluted mineral acids, it is broken up into dextrogyrate gum, sugar, and cellulose. (Kirchner and Tollens, *Ann. Ch. Ph.*, clxxv, 215.) For further information on the histology and pharmacognosy of the flaxseed, see Winton and Moeller, "The Microscopy of Vegetable Foods;" Kate B. Winton, *Bot. Gaz.*, lviii, p. 2445; Collin, *J. P. C.*, 1909, xxix, p. 369.

Jorissen and Hairs (*Drogues Simples*, t. ii, 685) obtained from the young plant a glucoside, to which they gave the name of *linamarin*, which crystallizes in colorless needles, melting at 134° C. (273.2° F.), without odor, but possesses a fresh and bitter taste. It differs from amygdalin in not being decomposed by emulsin, but diluted acids decompose it into sugar, hydrocyanic acid, and a third product which is volatile and possesses certain of the characters of the acetones. No benzaldehyde is formed. Linseed contains about 4 per cent. of nitrogen, corresponding to about 25 per cent. of proteid substances. After expression of the oil these substances remain in the cake, so that the latter contains 5 per cent. of nitrogen and constitutes a very important article for feeding cattle and is termed *cake meal*. The interior of the seed, or nucleus, is rich in a peculiar oil, which is separated by expression, and extensively employed in the arts on account of its drying properties. (See *Oleum Lini.*)

Uses.—Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in *catarrh, dysentery, nephritic* and *calculous complaints, strangury,* and other inflammatory affections of the mucous membrane of the lungs, intestines, and urinary passages. The whole seed is occasionally given in tablespoonful doses as a laxative. By decoction, water extracts a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

LIQUOR ACIDI ARSENOSI. U. S. (Br.)

SOLUTION OF ARSENOUS ACID Liq. Acid. Arsen. [Hydrochloric Solution of Arsenic Solution of Arsenic Chloride]

(lĭ'quŏr ăç'ĭ-dī är-sē-nō'sī)

"An aqueous solution, containing arsenous acid equivalent to not less than 0.975 per cent. nor more than 1.025 per cent. of As_2O_3 (197.92)." *U. S.*

Liquor Arsenici Hydrochloricus, *Br.;* Liquor Arsenici Chloridi, *U. S. P.* 1870; Soluté d'Acide Arsénieux, *Fr. Cod.*; Liqueur de Boudin, Liqueur arsénicale hydrochlorique, *Fr.*; Chlorarsenik-Lösung, *G.*

* "Arsenic Trioxide, *ten grammes* [or 154 grains]; Diluted Hydrochloric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the diluted hydrochloric acid with *two hundred and fifty grammes* [or 8 ounces av., 358 grains] of distilled water, in a tared flask, add the arsenic trioxide, and boil until the arsenic trioxide is completely dissolved. Then allow it to cool, add enough distilled water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains] and filter." *U. S.*

"Arsenious Anhydride, in powder, 10 *grammes;* Hydrochloric Acid, 12 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Dissolve the Arsenious Anhydride and the Hydrochloric Acid in five hundred *millilitres* of Distilled Water by the aid of heat; cool; add sufficient Distilled Water to produce the required volume." *Br.*

This solution is stronger than the *Liquor Arsenici Chloridi* of the U. S. P., 1870. The name has also been changed, as the former title was a misnomer. The hydrochloric acid does not enter into combination with the arsenic trioxide; it merely aids in its solution. True arsenic chloride, As_2Cl_6, cannot exist in aqueous solution but is immediately hydrolized into arsenous and hydrochloric acids. The British title is, in our opinion, to be preferred, because the U. S. name does not indicate the presence of the hydrochloric acid.

Properties.—"Solution of Arsenous Acid is a clear, colorless liquid, odorless, having an acidulous taste and an acid reaction. Hydrogen sulphide T.S., added to Solution of Arsenous Acid, produces a lemon-yellow precipitate of arsenic trisulphide which is completely soluble in ammonium carbonate T.S.

"**Assay.**—Dilute about 20 mils of Solution of Arsenous Acid, accurately weighed, with about 50 mils of distilled water, dissolve 2 Gm. of sodium bicarbonate in this solution and titrate with tenth-normal iodine V.S., using starch T.S. as indicator. It shows not less than 0.975 per cent. nor more than 1.025 per cent. of As_2O_3.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.004948 Gm. of As_2O_3. Each gramme of Solution of Arsenous Acid corresponds to not less than 1.97 nor more than 2.07 mils of tenth-normal iodine V.S." *U. S.*

According to the British Pharmacopœia, it is "a colorless liquid; acid to *litmus*. 25 millilitres diluted with *water* discharge the color of 50.4 millilitres of *N/10 solution of iodine,* the presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation. This Solution contains 1 gramme of Arsenious Anhydride in 100 millilitres; 110 minims contain 1 grain." *Br.*

Uses.—The medicinal properties of this solution are the same as those of Fowler's solution, with which it corresponds in strength, being

nearly three times as strong as the former London solution of arsenic chloride.

Dose, from two to eight minims (0.12–0.5 mil).

LIQUOR ACIDI CHROMICI. Br.

SOLUTION OF CHROMIC ACID

(lĭ'quŏr ăç'ĭ-dī ȼhrō'mĭ-cī)

Soluté d'Acide Chromique, *Fr. Cod.;* Chromsaurelösung, *G.*

"Chromic Anhydride, 25 *grammes;* Distilled Water sufficient to produce 100 *millilitres.* Dissolve." *Br.*

This was officially described in the British Pharm., 1898, as "an orange-red, inodorous, caustic, strongly acid liquid. Specific gravity, 1.185. It should respond to the tests described under 'Acidum Chromicum.'"

It is simply a definite solution of chromic anhydride (25 per cent.), and will probably be found convenient as a caustic application. (See *Chromii Trioxidum,* p. 330.) It is not used internally.

LIQUOR ADRENALINI HYDROCHLORICUS. Br.

HYDROCHLORIC SOLUTION OF ADRENALIN

(lĭ'quŏr ăd-rĕn-ą-lī'nī hȳ-drọ-ȼhlō'rĭ-cŭs)

Solution of Adrenalin Hydrochloride; Solution of Epinephrine hydrochloride.

"Adrenalin, 1 *gramme;* Chloroform, 5 *millilitres;* Sodium Chloride, 9 *grammes;* Diluted Hydrochloric Acid, 3 *millilitres;* Distilled Water, recently boiled and cooled, sufficient to produce 1000 *millilitres.* Dissolve the Chloroform and the Sodium Chloride in nine hundred *millilitres* of the Distilled Water, add the Diluted Hydrochloric Acid, dissolve the Adrenalin in the mixture, and add sufficient Distilled Water to produce the required volume. Preserve the Solution in amber glass bottles." *Br.*

Solution of adrenalin hydrochloride devised by Dr. Jokichi Takamine is a protected preparation marketed by Parke, Davis & Co., of Detroit, and has had a large sale throughout the world. The U. S. P. IX could not make it official under the name of adrenalin because it is a proprietary preparation. The British Pharmacopœia, 1914, however, with the consent of the firm introduced the "hydrochloric solution of adrenalin." This solution contains free acid and sodium chloride with a little chloroform to act as a preservative. Care should be used to avoid the presence of iron in compounding prescriptions as it is incompatible. Steel spatulas must not be brought in contact with adrenalin solutions. In fact, it is desirable to prescribe the solution without admixture, and in original containers. C. P. Beckwith in the *Bulletin of Pharmacy,* 1915, page 129, gives an excellent résumé of the incompatibilities of adrenalin solution. (See *Adrenalin,* page 94.)

When adrenalin is to be incorporated with ointments or with oily nasal sprays it is recommended that the oily solution known as *adrenalin inhalent* be used; it contains the same per cent. of adrenalin as the solution. The use of metallic spatulas or containers must be avoided in dispensing such ointments.

For uses of this solution, see *Adrenalinum.*

Dose, five to twenty minims (0.3–1.3 mils).

LIQUOR AMMONII ACETATIS. U. S., Br.

SOLUTION OF AMMONIUM ACETATE Liq. Ammon. Acet. [Spirit of Mindererus]

(lĭ'quŏr ąm-mō'nī-ī ăç-ę-tā'tĭs)

"An aqueous solution containing not less than 7 per cent. of $NH_4C_2H_3O_2$ (77.07), with small amounts of acetic and carbonic acids." *U. S.*

Spiritus Mindereri; Liquor Ammoniæ Acetatis; Acétate d'Ammoniaque liquide, *Fr. Cod.;* Esprit de Mindérérus, *Fr.;* Liquor Ammonii Acetici, *P. G.;* Ammoniumacetatlösung, Essigsaure Ammoniumlösung, *G.*

* "Ammonium Carbonate, *five grammes* [or 77 grains]; Diluted Acetic Acid, *one hundred mils* [or 3 fluidounces, 183 minims]. Add the ammonium carbonate (which must be in hard translucent pieces), gradually to the cold diluted acetic acid, and stir until it is dissolved. This preparation must not be dispensed unless it has been recently prepared." *U. S.*

"Acetic Acid, 162.5 *millilitres;* Ammonium Carbonate, 50.0 *grammes,* or a sufficient quantity; Distilled Water sufficient to produce 1000.0 *millilitres.* Mix the Acetic Acid with five hundred *millilitres* of the Distilled Water; neutralise with Ammonium Carbonate; add sufficient Distilled Water to produce the required volume." *Br.*

This preparation is an aqueous solution of ammonium acetate. The U. S. process by which it is formed involves the decomposition of ammonium carbonate by diluted acetic acid. The formula of commercial ammonium carbonate is complex, but the reaction is expressed by the following equation:

$$CO(OH)ONH_4.CO(NH_2)ONH_4 + 3(C_2H_3O_2.H) = 3(C_2H_3O_2.NH_4) + H_2O + 2CO_2$$

Distilled vinegar was formerly used, but it was replaced by diluted acetic acid, which is much to be preferred. The quantity of ammonium carbonate necessary to saturate a given weight of the acid of average strength cannot be laid down with precision, on account of the variable quality of the salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopœia, contains about 7 per cent. of ammonium acetate. It is more convenient to add the salt to the acid than to add the acid to the salt, as the point of saturation is thus more easily attained. In ascertaining this point by test paper, the alkaline reaction will begin, though a portion of free acetic acid may still remain, a little of it being insufficient to overcome the natural alkaline reaction of the salt. A complication is caused by the presence of

free carbon dioxide, which may be expelled from the liquid towards the end of the saturation by warming it.

The formula of the U. S. P., 1890, differed from that formerly official in dropping what has been called the "mixed solution process," and the U. S. P. IX has retained the 1890 process without change. It is to be regretted that the official process does not direct the preparation of two solutions, one of acetic acid, the other of ammonium carbonate, these solutions to be mixed in equal volumes to prepare the official solution of ammonium acetate. The separate solutions keep well, and the rapidity and ease with which this preparation can be made by the pharmacist, are advantages which at once recommend its exclusive use, while the physician is more likely to secure a fresh preparation, and one which usually retains a quantity of carbon dioxide to render the preparation grateful to the patient.

As some pharmacists will prefer to make solution of ammonium acetate in this way, the following procedure is suggested: Ammonium Carbonate, *ten grammes* [or 1 ounce av., 293 grains]; Acetic Acid (36 to 37 per cent.), *thirty-four mils* [or 5 fluidounces, 211 minims]; Distilled Water, sufficient to make *two hundred mils* [or two pints]. Dissolve the Ammonium Carbonate in sufficient Distilled Water to make *one hundred mils* [or 1 pint], and filter the solution. Then to the Acetic Acid add enough Distilled Water to make *one hundred mils* [or 1 pint]. Keep the solutions in separate, well-stoppered bottles, and when solution of ammonium acetate is to be dispensed measure equal quantities of each solution and mix them.

The present British process does not differ essentially from ours; in the older Br. Pharmacopœias the strong solution of ammonia was used instead of the carbonate, and the ammonia combined directly with the acetic acid, without other reaction. There was an advantage in this process in the use of ammonia instead of its carbonate, as the difficulty of ascertaining the precise point of saturation arising from carbon dioxide was avoided, but in this solution, as in the neutral mixture, a great benefit remedially is gained by the presence of carbonic acid, which reconciles the stomach to the medicine, and sometimes even allays vomiting in febrile diseases. With this view of the subject it is better to use ammonium carbonate; the change has been made in the present Br. Pharmacopœia, but the advantages are practically lost because the solution is nearly always made in advance of actual use, and official solution of ammonium acetate is rarely sparkling, but as generally dispensed it has a flat, mawkish taste, quite in contrast with that made by the "mixed solution process."

Properties.—Solution of ammonium acetate is "a clear, colorless liquid, free from empyreumatic odor and having a mildly saline, acidulous taste, and an acid reaction. It is volatile when heated. Not more than 0.003 Gm. of ash remains on evaporating 20 mils of the Solution and igniting the residue. When Solution of Ammonium Acetate is heated with potassium hydroxide T.S., ammonia is evolved. Add 1 mil each of sulphuric acid and alcohol to 5 mils of the Solution and boil the mixture; ethyl acetate is formed, recognizable by its odor.

"**Assay.**—Dilute about 25 mils of Solution of Ammonium Acetate, accurately weighed, with 100 mils of distilled water, transfer it to a distilling flask, render it alkaline with potassium hydroxide T.S. and distil the liquid until all of the ammonia has been driven over (about 100 mils of distillate), receiving the distillate under the surface of 50 mils of normal sulphuric acid V.S, contained in a flask. Then titrate with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows not less than 7 per cent. of $NH_4C_2H_3O_2$.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.07707 Gm. of $NH_4C_2H_3O_2$. Each gramme of Solution of Ammonium Acetate corresponds to not less than 0.91 mil of normal sulphuric acid V. S." *U. S.*

"Specific gravity 1.016. Mixed with an equal volume of a saturated aqueous solution of *hydrogen sulphide* not more than the slightest darkening in color results (limit of heavy metals). Solution of Ammonium Acetate should be preserved in a vessel free from lead." *Br.*

When it contains an excess of alkali, its taste is bitterish. It should be freshly prepared at short intervals, as its acid becomes decomposed and a portion of ammonium carbonate is generated. When pure it is not precipitated by barium chloride.

Ammonium acetate is a salt of difficult crystallization, and very deliquescent. It may be obtained by sublimation from a mixture of equal parts of dry potassium or calcium acetate and ammonium chloride, or, according to Berthelot, by dissolving glacial acetic acid in ammonia water, keeping the retort cool, and adding enough water to prevent the crystallization of the salt during the neutralization; the solution is then evaporated in a current of dry, gaseous ammonia until the liquid solidifies on cooling. It is then introduced into a large dish, and this placed upon caustic lime, under a large bell glass, into which a considerable quantity of ammonia gas is injected. After a few days the crystalline mass is broken, and the dish replaced as before upon lime in an ammoniacal atmosphere, under the bell glass. When this operation has been repeated several times, a perfectly pure ammonium acetate is obtained, which crystallizes in large needles, like potassium nitrate, and resembles ammonium formate; it is extremely soluble in water, and does not possess an acid reaction. (*A. J. P.*, 1875, p. 25.) It is formed by the union of one molecule of acetic acid, $H.C_2H_3O_2$, with one group, NH_4, from $NH_4.OH$, the hydroxide, or $(NH_4)_2CO_3$, the carbonate. When evaporated to dryness, however, it readily yields an acid salt, $C_2H_3O_2.NH_4 + C_2H_3O_2.H$.

Uses.—Solution of ammonium acetate is used as a saline diaphoretic and diuretic, especially in febrile conditions.

Dose, from half a fluidounce to a fluidounce and a half (15–45 mils) every three or four hours, mixed with water and sweetened with sugar.

Off. Prep.—Liquor Ferri et Ammonii Acetatis, *U. S.*

LIQUOR AMMONII CITRATIS. Br.

SOLUTION OF AMMONIUM CITRATE

(lĭ'quŏr ăm-mō'nĭ-ī cĭ-trā'tĭs)

Citrate d'Ammoniaque liquide, *Fr.;* Ammoniumcitratlösung, Citronensaure Ammoniak-Flüssigkeit, *G.*

"Citric Acid, 125.0 *grammes;* Ammonium Carbonate, 87.5 *grammes,* or a sufficient quantity; Distilled Water sufficient to produce 1000.0 *millilitres.* Dissolve the Citric Acid in five times its weight of Distilled Water; neutralise with Ammonium Carbonate; add sufficient Distilled Water to produce the required volume. Specific gravity, 1.057. Mixed with an equal volume of a saturated aqueous solution of *hydrogen sulphide* not more than the slightest darkening in color results (limit of heavy metals). Solution of Ammonium Citrate should be preserved in a vessel free from lead." *Br.*

This solution is also official in the N. F. IV. (See Part III.)

This solution may be used for the same purposes as *Solution of Ammonium Acetate.*

Dose, from two to six fluidrachms (7.5–22.5 mils).

LIQUOR ARSENI ET HYDRARGYRI IODIDI. U. S. (Br.)

SOLUTION OF ARSENOUS AND MERCURIC IODIDES

Liq. Arsen. et Hydrarg. Iod. [Donovan's Solution]

(lĭ'quŏr ăr'sẹ-nī ĕt hy-drär'gy-rī ī-ŏd'ĭ-dī)

"An aqueous solution containing not less than 0.95 per cent. nor more than 1.05 per cent. of AsIs (455.72) and not less than 0.95 per cent. nor more than 1.05 per cent. of HgI_2 (454.44)." *U. S.*

Liquor Arsenii et Hydrargyri Iodidi, *Br.,* Solution of Arsenious and Mercuric Iodides; Liquor Arsenici et Hydrargyri Iodidi, *Br.* 1867, *U. S.* 1870; Solution of Hydriodate of Arsenic and Mercury; Solutio Donovani; Soluté d'Iodo-arsénite de Mercure, Liqueur de Donovan, *Fr.;* Jodquecksilber Arseniklösung, Donovansche Tropfen, *G.*

* "Arsenous Iodide, *ten grammes* [or 154 grains]; Red Mercuric Iodide, *ten grammes* [or 154 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the arsenous iodide and red mercuric iodide together in a mortar, add *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of distilled water, and continue the trituration until solution is effected. Filter the solution, and pass sufficient distilled water through the filter to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Mix thoroughly. Preserve it in well-filled, amber-colored bottles. It must not be dispensed if darker than pale yellow." *U. S.*

"Arsenious Iodide, 10 *grammes;* Red Mercuric Iodide, 10 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Triturate the Arsenious Iodide and Red Mercuric Iodide with two hundred and fifty *millilitres* of the Distilled Water until dissolved; filter; pass through the filter sufficient Distilled Water to produce the required volume. This Solution contains the equivalent of 1 gramme of Arsenious Iodide and 1 gramme of Red Mercuric Iodide in 100 millilitres; 110 minims contain the equivalent of 1 grain of each salt." *Br.*

This solution was introduced to the notice of the medical profession in 1839 by Donovan, of Dublin, as a therapeutic agent combining the medicinal virtues of its three ingredients, and was adopted as an official preparation in the U. S. and Dublin Pharmacopœias of 1850. It was dropped from the British Pharmacopœia of 1867, but reintroduced in the 1885 revision, and fortunately made to correspond in strength with the U. S. preparation—namely, 1 per cent. of each of the active ingredients. The formula of the U. S. Pharmacopœia is the simplified one of Procter, which consists essentially in dissolving equal weights of arsenic triiodide and mercuric iodide (red iodide) in a measured quantity of distilled water.

Properties.—"Solution of Arsenous and Mercuric Iodide is a clear, colorless or pale yellowish liquid, without odor, and having a disagreeable metallic taste. One mil of Solution of Arsenous and Mercuric Iodide, mixed with 10 mils of distilled water, to which a few drops of lead acetate T.S. have been added, produces a bright yellow precipitate. Add a few drops of Solution of Arsenous and Mercuric Iodide to a mixture of about 0.5 Gm. of zinc and 5 mils of diluted hydrochloric acid in a test tube, and cover the mouth of the test tube with a filter paper which has been moistened with mercuric chloride T.S. and dried; a yellow stain appears upon the inner surface of the filter paper within one minute.

"**Assay for Arsenous Iodide.**—Introduce about 25 mils of Solution of Arsenous and Mercuric Iodide into a flask, weigh accurately, dilute with 25 mils of distilled water, then dissolve 2 Gm. of sodium bicarbonate in this solution and titrate it with tenth-normal iodine V.S., using starch T.S. as indicator. It shows not less than 0.95 per cent. nor more than 1.05 per cent. of AsIs.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.022786 Gm. of AsIs. Each gramme of Solution of Arsenous and Mercuric Iodide corresponds to not less than 0.42 mil nor more than 0.46 mil of tenth-normal iodine V.S.

"**Assay for Mercuric Iodide.**—Introduce about 25 mils of Solution of Arsenous and Mercuric Iodide into a flask, weigh accurately, add 5 mils of potassium hydroxide T.S. and 5 mils of solution of formaldehyde, and warm the mix-

ture on a water bath until the mercuric salt has been completely reduced to metallic mercury. Carefully decant the clear, supernatant liquid from the residue of metallic mercury and wash the mercury carefully by decantation, with two successive portions of 25 mils each of distilled water. Dissolve the residue of metallic mercury in 5 mils of nitric acid, dilute the solution with 50 mils of distilled water, add 2 mils of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium sulphocyanate V.S. to the formation of a permanent pink color. It shows not less than 0.95 per cent. nor more than 1.05 per cent. of HgI_2.

"Each mil of tenth-normal potassium sulphocyanate V.S. corresponds to 0.022722 Gm. of HgI_2. Each gramme of Solution of Arsenous and Mercuric Iodide corresponds to not less than 0.42 mil nor more than 0.46 mil of tenth-normal potassium sulphocyanate V. S." *U. S.*

Uses.—This preparation has been found decidedly useful as an alterative in various chronic diseases of the skin, such as in the later stages of *syphilis,* especially with "night pains;" in certain cases of *lymphadenitis* and in some forms of chronic joint disease.

Dose, from one to five minims (0.06–0.3 mil), three times a day, given preferably in distilled water.

LIQUOR ATROPINÆ SULPHATIS. Br.

SOLUTION OF ATROPINE SULPHATE

(lĭ'quŏr ăt-rŏ-pī'næ sŭl-phā'tĭs)

Soluté de Sulfate d'Atropine, *Fr.;* Schwefelsaure Atropin-lösung, *G.*

"Atropine Sulphate, 1 *gramme;* Distilled Water, recently boiled and cooled, sufficient to produce 100 *millilitres.* Dissolve. This Solution should be freshly prepared. It contains 1 gramme of Atropine Sulphate in 100 millilitres; 110 minims contain 1 grain." *Br.*

This solution contains 1 per cent. of atropine sulphate. Camphor water was substituted for distilled water on account of its antiseptic properties at the 1885 revision. Salicylic acid and distilled water were used (1898) with the same object in view, but the British Pharm., 1914, discarded preservatives.

Dose, one-half to one minim (0.03–0.06 mil).

LIQUOR BISMUTHI ET AMMONII CITRATIS. Br.

SOLUTION OF BISMUTH AND AMMONIUM CITRATE

(lĭ'quŏr bĭs-mū'thī ĕt ăm-mō'nī-ī cĭ-trā'tĭs)

Liquor Bismuthi; Solution of Bismuth, Liquid Bismuth; Soluté de Citrate de Bismuth ammoniacal, *Fr.;* Citronensaure Wismuth-Ammoniak-Lösung, Wismuth-Ammoniakcitratlösung, *G.*

"Bismuth Oxynitrate, 70 *grammes;* Citric Acid, 52 *grammes;* Solution of Ammonia, Distilled Water, of each, *a sufficient quantity.* Powder the Citric Acid and mix it in a mortar with the Bismuth Oxynitrate and twenty *millilitres* of Distilled Water. Allow the mixture to stand, with occasional stirring, for half an hour, or until a small portion is completely soluble in Solution of Ammonia. Transfer to a beaker, using four hundred *millilitres* of Distilled Water to rinse the mortar. Allow the precipitate to settle, remove the clear liquid by decantation, and wash the precipitate with three successive quantities, each of four hundred *millilitres,* of Distilled Water. Add to the washed precipitate, while moist, just sufficient Solution of Ammonia to dissolve it, and then add sufficient Distilled Water to produce one thousand *millilitres* of the Solution." *Br.*

Some years since, a secret preparation was made and sold by Schacht, of Clifton, England, under the name of *Liquor Bismuthi,* which was shown by Tichborne (*P. J.,* 1864, 301) to contain bismuth oxide, ammonia, and citric acid. Various formulas for a similar solution have been suggested (see *U. S. D.,* 17th ed., 794, and 19th ed., 706), but that official is probably as good as any.

The British Pharmacopœia describes this preparation as "a colorless liquid, freely miscible with *water;* taste somewhat metallic; slightly alkaline to *litmus.* Evolves ammonia when heated with *solution of sodium hydroxide.* 10 millilitres, evaporated to dryness and the residue ignited, yield not less than 0.5 gramme of bismuth oxide." *Br.*

Bismuth and ammonium citrate, obtained by Bartlett's process, is in fine, glossy, translucent, colorless scales, of a slightly acidulous, somewhat metallic, not disagreeable taste, very soluble in water, but not deliquescent, and of an acid reaction. (See page 236.) From an analysis by Bartlett, it appears to possess the formula $Bi,C_6H_5O_7.NH_3 + 3H_2O$. Rother, however (1876), considers that the formula should be written $C_6H_5O_7(NH_4)_3Bi(OH)_3$.

Uses.—This preparation is much more astringent than are the insoluble salts of bismuth, and is at the same time irritant, and not possessed of the peculiar medicinal properties which grow out of insolubility of the subnitrate or subcarbonate. It is, therefore, not a substitute for these, and is adapted to the treatment of *diarrheas* of relaxation rather than of irritation.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

LIQUOR CALCIS. U. S., Br.

SOLUTION OF CALCIUM HYDROXIDE Liq. Calc. [Lime Water]

(lĭ'quŏr căl'cĭs)

"An aqueous solution containing not less than 0.14 per cent. of $Ca(OH)_2$ (74.09) at 25° C. (77° F.). Preserve it in well-filled, tightly-stoppered bottles. The percentage of calcium hydroxide varies with the temperature at which the solution is prepared, being about 0.17 per cent. at 15° C. (59° F.), and diminishing as the temperatures rises." *U. S.*

Aqua Calcariæ Ustæ, Calcaria Soluta, Aqua Calcis; Solution of Calcium Hydrate, Solution of Lime; Eau (Solutè) de Chaux, *Fr. Cod.*; Aqua Calcariæ, *P. G.*; Kalkwasser, *G.*; Acqua di calce, *It.*; Agua de cal, *Sp.*

* "Lime, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *a sufficient quantity.* Slake the lime by the very gradual addition of *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of distilled water, and agitate it occasionally during half an hour. Allow the suspended particles to subside, decant the supernatant liquid and reject it. Transfer the magma of calcium hydroxide to a filter and wash it repeatedly with boiling distilled water, until the washings, after acidulation with nitric acid, show not more than a faint cloudiness with silver nitrate T.S. (*chloride*). Return the magma to a suitable container, add *five thousand mils* [or 169 fluidounces, 33 minims] of distilled water, agitate it thoroughly, allow the mixture to stand for twenty-four hours, agitate again, and, when the coarser particles of solid matter have subsided pour the liquid, holding the undissolved calcium hydroxide in suspension, into a bottle having a tight stopper. From time to time shake the bottle to insure a saturated solution. Pour off the clear liquid when required for use. The undissolved calcium hydroxide must not be used for making additional quantities of Solution of Calcium Hydroxide unless the product is found to be of full strength when assayed." *U. S.*

"Calcium Hydroxide, 50 *grammes;* Distilled Water, *a sufficient quantity.* Wash the Calcium Hydroxide with Distilled Water until free from chlorides; then shake it with five thousand *millilitres* of Distilled Water in a stoppered green glass bottle for two or three minutes; set aside until clear. The clear Solution may be drawn off with a siphon as required for use, and should then be transferred to a green glass bottle." *Br.*

A solution of calcium hydroxide, $Ca(OH)_2$, in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to both Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved hydroxide, which causes it always to be saturated whatever may be the temperature and to whatever extent it may be exposed to the air. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. The employment of distilled water as the solvent may seem a useless refinement, but in many places the common water is very impure. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than when cold. Hence the propriety of employing cold water in the process. According to Phillips, a pint of water (the wine pint of the U. S. P., 1870) at 100° C. (212° F.) dissolves 5.6 grains of lime, at 15.5° C. (60° F.) 9.7 grains. For Green's automatic device for dispensing lime water in excellent condition, see *Proc. A. Ph. A.*, 1893, 474; see also 1904, 66.

The practice of using the undissolved lime indefinitely by refilling the bottle with water, is reprehensible, as notwithstanding the excess, its tendency to become carbonated and insoluble is great, and lime water is often dispensed deficient in strength; it is much safer to use the lime but once or twice than to run the risk of dispensing a liquid of insufficient strength.

Properties.—Lime water is "a clear, colorless liquid without odor, and having an alkaline taste. It is strongly alkaline to litmus. It absorbs carbon dioxide from the air, a pellicle of calcium carbonate forming on the surface of the liquid. On being heated it becomes turbid, due to the separation of calcium hydroxide which redissolves when the liquid is cooled. The alkaline reaction of the Solution entirely disappears after it has been saturated with carbon dioxide and subsequently boiled (*alkalies and their carbonates*).

"**Assay.**—Titrate 50 mils of Solution of Calcium Hydroxide with tenth-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator; it shows not less than 0.14 per cent. of $Ca(OH)_2$.

"Each mil of tenth-normal sulphuric acid V.S. used corresponds to 0.0037045 Gm. of $Ca(OH)_2$. Each mil of Solution of Calcium Hydroxide corresponds to not less than 0.38 mil of tenth-normal sulphuric acid V.S." *U. S.*

"Twenty-four millilitres require for neutralisation 10 millilitres of *N/10 solution of sulphuric acid.* Yields no characteristic *reactions* for lead or chlorides. This Solution contains the equivalent of rather more than 0.1 gramme of Lime, CaO, in 100 millilitres; 110 minims contain the equivalent of 1/10 grain." *Br.*

Exposed to the air it attracts carbon dioxide, and becomes covered with a pellicle of insoluble calcium carbonate, which, subsiding after a time, is replaced by another, and so on successively until the whole of the lime is precipitated. Hence the necessity of keeping lime water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime.

Uses.—Lime water is mildly antacid, and astringent, often useful in *dyspepsia* with acidity of stomach or *diarrhea.* Mixed with from one to three measures of milk, which completely covers its offensive taste, it is of service in *nausea* and *vomiting* dependent on irritability of stomach. It is often added to milk to prevent the formation of hard curds, and thus increase its digestibility. In severe repeated vomiting with loss of digestive power a diet exclusively of lime water and milk (one to six) is often very effectual. Having been found to possess the property of dissolving false membrane, it has naturally been employed as a local remedy in *pseudo-membranous croup.* It may be applied by directing lime water spray, produced by the atomizer, so that it shall be inhaled by the patient. When employed to allay *nausea,* it is

usually given in the dose of a tablespoonful mixed with the same quantity of milk, and repeated at intervals of half an hour, an hour, or two hours.

Dose, one to four fluidounces (30–120 mils).

Off. Prep.—Linimentum Calcis, *U. S., Br.*

LIQUOR CALCIS CHLORINATÆ. Br.

SOLUTION OF CHLORINATED LIME

(lĭ'quŏr căl'cĭs ȼhlō-rĭ-nā'tæ)

Soluté d'Hypochlorite de Chaux, *Fr. Cod.;* Chlorure de Chaux liquide, *Fr.;* Chlorkalklösung, Chlorkalk-Flüssigkeit, *G.*

"Chlorinated Lime, 100 *grammes;* Distilled Water, 1000 *millilitres.* Mix; transfer the mixture to a stoppered bottle; set aside for three hours, shaking occasionally; filter through calico. Preserve the filtrate in a stoppered bottle in a cool dark place." *Br.*

For the properties and uses of this preparation, see *Calx Chlorinata.* The British Pharmacopœia gives the following tests: "If 2 *millilitres* are added to a solution of 1 gramme of *potassium iodide* in 25 *millilitres* of *water,* acidified with 2 *millilitres* of *hydrochloric acid,* a brownish-red solution is obtained which requires for decolorisation not less than 11.7 *millilitres* of *N/10 solution of sodium thiosulphate* (presence of not less than 2 per cent. of available chlorine). When freshly prepared, this Solution yields about 3 per cent. of available chlorine." *Br.*

This determines its strength in chlorine, by ascertaining the quantity of iodine which the chlorine contained in it is capable of separating from potassium iodide. Notwithstanding, however, that a test of its character is thus given by the Pharmacopœia, its strength must vary according to the quality of the chlorinated lime employed. It is one of the best antidotes against poisoning by hydrogen sulphide, ammonium sulphydrate, potassium sulphide, and hydrocyanic acid. For external application the solution may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections.

Dose, for internal use, from ten to thirty minims (0.6–1.9 mils).

LIQUOR CALCIS SACCHARATUS. Br.

SACCHARATED SOLUTION OF LIME

(lĭ'quŏr căl'cĭs săc-ȼhă-rā'tŭs)

Syrupus Calcis (*U. S. VIII*); Syrup of Lime; Syrup of Calcium Hydroxide; Syrupus Calcariæ; Syrup of Calcium Hydroxide; Sirop de Chaux, *Fr.;* Kalksyrup, *G.*

"Calcium Hydroxide, 50 *grammes;* Refined Sugar, in powder, 100 *grammes;* Distilled Water, 1000 *millilitres.* Mix the Calcium Hydroxide with a solution of the Refined Sugar in the Distilled Water. Set aside in a stoppered green glass bottle for a few hours, shaking occasionally; separate the clear Solution by means of a siphon, avoiding unnecessary exposure to air. Specific gravity, 1.055. Twenty millilitres require for neutralisation 13.2 millilitres of *N/1 solution of sulphuric acid.* Yields no characteristic *reactions for lead.* This Solution contains the equivalent of nearly 2 grammes of Lime, CaO, in 100 millilitres; 110 minims contain nearly 2 grains." *Br.*

Properties.—Syrup of Lime is not official in the U. S. P. IX. It was described in the U. S. P. VIII as "a transparent, pale yellow liquid, of alkaline taste and reaction. Specific gravity: about 1.145 at 25° C. (77° F.). The addition of a solution of an alkali carbonate produces a white precipitate, soluble in acids with effervescence. The addition of ammonium oxalate T.S. produces a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

The British saccharated solution of lime differs from the U. S. P. VIII syrup in containing a smaller proportion of sugar and of lime.

Sugar forms with lime certain definite compounds which may be looked upon as sucrates. According to M. S. Benedikt (*J. P. C.,* 4e sér., xix, 96), there are at least four of these combinations. Some, if not all, of them are much more soluble than the lime itself, so that in this way a much stronger solution of lime can be obtained than by the instrumentality of water alone. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered.

Uses.—Syrup of lime is an active antacid and astringent, which may be used as a substitute for lime water in all cases in which that preparation is suitable. Twenty minims of it (1.3 mils) are equal to a fluidounce of lime water.

Dose, fifteen to sixty minims (0.9–3.75 mils).

LIQUOR CRESOLIS COMPOSITUS.

U. S. (Br.)

COMPOUND SOLUTION OF CRESOL Liq. Cresol. Co.

(lĭ'quŏr crẹ-sō'lĭs cọm-pŏs'ĭ-tŭs)

Liquor Cresol Saponatus, *Br.;* Solution of Cresol with Soap; Soluté de Crésol composé, *Fr.;* Liquor Cresoli saponatus, *P. G.;* Kresolseifenlösung, *G.*

* "Cresol, *five hundred grammes* [or 17 ounces av., 279 grains]; Linseed Oil, *three hundred grammes* [or 10 ounces av., 255 grains]; Potassium Hydroxide, *eighty grammes* [or 2 ounces av., 360 grains]; Alcohol, *thirty mils* [or 1 fluidounce, 7 minims]; Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Heat the linseed oil in a tared vessel of a capacity equal to about four times the bulk of the ingredients, on a water bath to a temperature of 70° C. (158° F.). Dissolve the potassium hydroxide in 50 mils of water and warm the solution to 70° C. (158° F.), add it to the linseed oil and mix thoroughly; then incorporate the alcohol

and continue to heat the mixture without stirring until a small portion is found to be soluble in boiling water without the separation of oily drops. While yet warm add the cresol and mix thoroughly, maintaining the temperature at about 70° C. (158° F.) until a clear solution is produced. Finally add sufficient water to make the finished product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Note: In this process the 80 Gm. of potassium hydroxide may be replaced by 54 Gm. of sodium hydroxide." *U. S.*

"Cresol, 500 *grammes;* Castor Oil, 350 *grammes;* Potassium Hydroxide, 80 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix the Cresol with the Castor Oil and heat to 80° C. (176° F.). Dissolve the Potassium Hydroxide in seventy *millilitres* of the Distilled Water. Mix the two solutions and heat the mixture until one volume of it forms a clear liquid with ten volumes of Distilled Water. Cool, and add sufficient Distilled Water to produce the required volume." *Br.*

Compound Solution of Cresol was introduced into the U. S. P. (8th Rev.) to supply the demand for an antiseptic solution which mixes freely with water. With some samples of cresol there has been experienced some difficulty in securing immediately a clear solution, showing that combination has not been effected, but by allowing the mixture to stand with occasional stirring, the solution will become clear. LaWall and Cook (*A. J. P.,* 1906, 169) suggested a modification of the manipulation which secures a clear solution immediately. It was adopted by the Committee of Revision of the U. S. P. IX. The official process permits the alternative use of sodium hydroxide, which produces a product identical in appearance and probably of equal value with the one made from potassium hydroxide and at a greatly reduced cost.

Uses.—This solution is intended as a substitute for the many commercial preparations of cresol on the market. Although it forms a clear solution with distilled water, with tap water it becomes cloudy, owing to precipitation of lime soaps. This change, however, does not appear to interfere with its therapeutic properties. It is a powerful germicidal mixture, at least twice as strong as phenol as a destroyer of micro-organisms. It is also less caustic than phenol, but the statement that it is much less poisonous has been shown to be untrue. The *Chemist and Druggist of Australasia* reports in 1911 (vol. xxvi, p. 299) fifty-six deaths from lysol—a widely used proprietary brand of this solution. It is especially useful for sterilizing instruments and the skin, its soapy nature making it peculiarly valuable for the latter purpose. It may be diluted with from 30 to 90 times its bulk of water (3 per cent. to 1 per cent. solution). It has been used to a small extent internally as an antiseptic in *fermentative gastritis.*

Dose, one to two minims (0.06–0.12 mil).

LIQUOR EPISPASTICUS. Br.

BLISTERING LIQUID

(lī'quŏr ĕp-ĭ-spăs'tĭ-cŭs)

Linimentum Cantharidis; Liqueur Vésicant, Huile de Cantharides térébenthinée, *Fr.;* Spanischfliegenliniment, Blasenziehende Flüssigkeit, *G.*

"Cantharidin, 4 *grammes;* Castor Oil, 25 *millilitres;* Resin, 12 *grammes;* Acetone sufficient to produce 1000 *millilitres.* Dissolve. This Blistering Liquid contains approximately the same proportion of Cantharidin as the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This liquid is used in making the British Blistering Collodion. (See p. 374.) Greenish and Wilson propose that the official blistering liquid be prepared by the following formula: Cantharidin, 1 part; castor oil, 6 parts; rosin, 3 parts; acetic ether, enough to make 300 fluid parts. The castor oil and rosin are added to replace the natural fat of the cantharides, and are necessary to aid the absorption of the cantharides by the skin. (*P. J.,* 1898, 259.)

Off. Prep.—Collodium Vesicans, *Br.*

LIQUOR ETHYL NITRITIS. Br.

SOLUTION OF ETHYL NITRITE

(lī'quŏr ĕ'thĭl nī-trī'tĭs)

"Solution of Ethyl Nitrite contains not less than 2.5 or more than 3 per cent. by weight of ethyl nitrite in a mixture of ninety-five parts by volume of Absolute Alcohol with five parts by volume of Glycerin. The ethyl nitrite may be obtained by the interaction of alcohol (90 per cent.), sodium nitrite, and diluted sulphuric acid, at a low temperature. Solution of Ethyl Nitrite should be stored in small bottles." *Br.*

Soluté de Nitrite d'Ethyle, *Fr.;* Aethylnitritlösung, *G.*

This was a new official preparation in the Br. Ph., 1898; it might be called improved spirit of nitrous ether; it is difficult to explain the reason for its introduction without the dismissal of spirit of nitrous ether; the strength is very slightly greater than that of the British spirit (less than the U. S. spirit of nitrous ether), and a choice should be made between them. The addition of glycerin as a preservative and the substitution of absolute alcohol for rectified spirit, are relied upon to make a permanent solution. This method was proposed by Dunstan and Dymond (*P. J.,* 1888, 861), who believe that ethyl nitrite is the *sole* valuable constituent in spirit of nitrous ether; glycerin prevents loss of the very volatile ethyl nitrite, while the absence of water is secured by the use of absolute alcohol, water in the alcohol being shown to be the principal cause of decomposition and loss of ethyl nitrite. Solution of ethyl nitrite was strongly recommended by Leech, and the advantage claimed for it is that it is free from aldehyde. The increased cost, due to the use of absolute alcohol, will be apt to prevent the extensive use of the solution.

It is described as "a nearly colorless transparent liquid, of characteristic apple-like odor and taste. Specific gravity 0.823 to 0.826. When poured on an acidified strong solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids. Does not effervesce when shaken with *sodium bicarbonate* (absence of acid). 10 millilitres, mixed with 5 millilitres of *N/1 solution of sodium hydroxide* and 5 millilitres of *water*, do not assume a yellow color (absence of acetaldehyde). 1 volume, shaken briskly at intervals during five minutes in a brine-charged nitrometer with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid*, yields at 15.5° C. (60° F.), and normal pressure, not less than 6.5 or more than 7.8 volumes of nitric oxide gas." *Br.*

This preparation affords a means of giving ethyl nitrite internally.

Dose, from twenty to sixty minims (1.3–3.75 mils). (See *Spiritus Ætheris Nitrosi.*)

LIQUOR FERRI CHLORIDI. U. S. (Br.)

SOLUTION OF FERRIC CHLORIDE Liq. Ferr. Chlor. [Solution of Iron Perchloride]

(lĭ′quŏr fĕr′rī ȼhlō′rı̤-dī)

"An aqueous solution containing ferric chloride [$FeCl_3 = 162.22$], corresponding to not less than 10 per cent. nor more than 11 per cent. of Fe. Preserve it in glass-stoppered bottles protected from light." *U. S.*

"This Solution contains 20 grammes of Iron in 100 millilitres; 110 minims contain 20 grains." *Br.*

Liquor Ferri Perchloridi Fortis, *Br.;* Liquor Ferri Muriatici Oxydati, Strong Solution of Ferric Chloride, Solution of Chloride of Iron; Chlorure Ferrique dissous, *Fr. Cod.;* Soluté de Perchlorure de Fer, Chlorure Ferrique liquide, *Fr.;* Liquo-Ferri Sesquichlorati, *P. G.;* Flüssiges Eisenchlorid, Eisen chloridlösung, *G.;* Solucion de Cloruro Ferrico, *Sp.*

* "Iron, in the form of fine, bright wire, and cut into small pieces, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Hydrochloric Acid, *six hundred and eighty grammes* [or 23 ounces av., 432 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the iron wire into a flask having a capacity of about *two thousand mils* [or 67 fluidounces, 301 minims], pour upon it a mixture of *four hundred and twenty grammes* [or 14 ounces av., 357 grains] of hydrochloric acid and *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of distilled water, and heat the mixture on a water-bath for not less than one hour and fifteen minutes, or until effervescence ceases; then boil the liquid, filter it through paper, and, having rinsed the flask and iron wire with a little hot distilled water, pass the rinsings through the filter. To the filtered liquid add *two hundred and twenty grammes* [or 7 ounces av., 333 grains] of hydrochloric acid, then add the mixture slowly and gradually, in a stream, to *sixty-five grammes* [or 2 ounces av., 128 grains] of nitric acid contained in a tared capacious porcelain vessel, and warm gently. If the solution has acquired a black color, continue the addition of nitric acid, drop by drop, until red fumes are no longer evolved and the solution assumes a clear, reddish-brown color. After effervescence ceases, heat on a sand bath, stirring occasionally until the liquid is free from nitric acid, as indicated by the test given below. During the heating add distilled water from time to time to maintain about the original volume. Finally, add the remaining *forty grammes* [or 1 ounce av., 180 grains] of hydrochloric acid and enough distilled water to make the solution weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

"Iron, 70 *grammes;* Hydrochloric Acid, 410 *millilitres;* Nitric Acid, 30 *millilitres;* Distilled Water, *a sufficient quantity*. Place the Iron in a flask; add a mixture of two hundred and fifty millilitres of Hydrochloric Acid and one hundred and forty millilitres of Distilled Water; expose to a moderate temperature until effervescence ceases; then boil; filter from undissolved Iron; rinse the flask and contents with a little Distilled Water; pour the rinsings over the filter; add to the filtrate one hundred and forty millilitres of Hydrochloric Acid; mix; pour the solution in a slow continuous stream into the Nitric Acid, chemical action being promoted if necessary by gently warming; evaporate the product until a precipitate begins to form; add twenty millilitres of Hydrochloric Acid, and sufficient Distilled Water to produce three hundred and fifty millilitres, or to make the resulting Solution respond to the following tests." *Br.* (See page 634.)

The strength of solution of ferric chloride U. S. P. (8th Rev.) was reduced from the former standard of 13 per cent. of iron (U. S. P., 1890) to 10 per cent. of iron, which corresponds to the solution of the German Pharmacopœia; this strength is sufficient for all purposes, and is more convenient for calculations. The U. S. P. IX strength is from 10 to 11 per cent. The British preparation contains 15.84 per cent. of iron. By the reaction between the hydrochloric acid and the iron, ferrous chloride is produced, which by the subsequent agency of the hydrochloric and nitric acids is converted into ferric chloride, or, as it is denominated in the British Pharmacopœia, perchloride of iron, this being retained in solution by the water with the excess of acid. This excess of acid is limited by a special test in the U. S. P. IX, because too great excess would complicate other formulas in which the tincture is used, such as the tincture of ferric citro-chloride. This solution was included in the original British Pharmacopœia, but was not official with us until 1870. The original British formula (1864) was defective in several respects. For an account of these, see the 13th edition of this book. The formula for the present British solution has been modelled after that of the U. S. Pharmacopœia.

When iron is treated with hydrochloric acid there is a copious evolution of hydrogen, and an emerald-green solution of ferrous chloride ($FeCl_2$) results. Green crystals having the composition $FeCl_2,4H_2O$ separate if the solution is permitted to rest. In the official process, water is added to the hydrochloric acid in order to retain the crystals in solution, and the mixture is heated while still in contact with the excess of iron, in order to hasten the complete conversion of all the hydrochloric acid into ferrous chloride. The action slackens very materially as the quantity of hydrochloric acid is gradually lessened in the mixture, but when it is brought, as officially directed, to the boiling point, a saturated solution is produced. After filtering from the excess of iron, half the original quantity of hydrochloric acid is added—this for the purpose of supplying the amount which is requisite to form the solution of ferric chloride—and the mixture is then gradually poured into nitric acid, which at once converts the solution of green ferrous chloride into the solution of red ferric chloride. Formerly the nitric acid was added to the solution; now the order is reversed, in accordance with the recommendation of C. L. Diehl, to prevent frothing. (See *A. J. P.*, 1867, p. 140.) The reaction between the acids and the solution may be thus expressed:

$$\underset{\text{Ferrous chloride.}}{6FeCl_2} + \underset{\text{Nitric acid.}}{2HNO_3} + \underset{\text{Hydrochloric acid.}}{6HCl} =$$

$$\underset{\text{Ferric chloride.}}{6FeCl_3} + \underset{\text{Nitrogen dioxide.}}{N_2O_2} + \underset{\text{Water.}}{4H_2O}$$

If the solution should have a black color, and not a clear ruby-red, it is due to the presence of a nitro-compound composed of a portion of ferrous chloride and nitrogen dioxide, $FeCl_2 + N_2O_2$. As this compound is easily decomposed, all that is necessary is to heat the liquid and add a few drops of nitric acid, when the black color soon disappears, nitrogen dioxide is liberated, and a ruby-red solution remains. Any excess of nitric acid is to be evaporated. The final addition of hydrochloric acid is to compensate for any loss which may have been suffered by heating the solution, and to secure an excess of the acid in the finished preparation; otherwise a reddish-brown deposit of oxychloride would gradually form, and precipitation would result upon dilution with alcohol in making the official tincture.

The use of chlorine instead of nitric acid for converting the ferrous chloride to the ferric condition is advocated by C. W. Weiss (*Ph. Ztg.; N. R.*, 1883, p. 247), and J. W. England devised a process, based upon such substitutions. (See *U. S. D.*, 19th ed., p. 714.)

The solution of ferric chloride, properly made, is "a reddish-brown liquid, having a faint odor of hydrochloric acid, an acid, strongly styptic taste, and an acid reaction. Specific gravity: from 1.29 to 1.32 at 25° C. (77° F.). Separate portions of an aqueous dilution of the Solution (1 in 10) yield a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in nitric acid, with silver nitrate T.S. Precipitate the iron completely from a weighed portion of about 2 mils of the Solution, previously diluted with 50 mils of distilled water, by adding an excess of ammonia water and filter. The filtrate is colorless, and does not yield a precipitate with hydrogen sulphide T.S. (*zinc, lead or copper*); nor does it leave on evaporation and ignition a fixed residue corresponding to more than 0.1 per cent. of the amount taken (*salts of the fixed alkalies*). Add a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of sulphuric acid and an aqueous dilution of the Solution (1 in 10); the crystal does not become brown nor does a brownish-black color develop around it (*nitric acid*). Add a few drops of freshly prepared potassium ferricyanide T.S. to an aqueous dilution of the Solution (about 1 in 20); a brown color is produced which does not at once turn green or greenish-blue (*ferrous salts*). To about 0.5 Gm. of Solution of Ferric Chloride, accurately weighed, add 10 mils of distilled water and 50 mils of tenth-normal silver nitrate V.S., shake it vigorously, then add 2 mils of nitric acid and sufficient distilled water to measure exactly 100 mils, and mix well. Filter the mixture through a dry filter (rejecting the first filtrate) and determine the excess of silver nitrate in 50 mils of the filtrate by titration with tenth-normal potassium sulphocyanate V.S. The percentage of chlorine found is not less than 3 per cent. nor more than 5 per cent. in excess of that required to combine with the iron present as ferric chloride. The percentage of iron found, multiplied by 1.9, gives the percentage of chlorine combined as ferric chloride (*free hydrochloric acid*). Each mil of tenth-normal silver nitrate V.S. corresponds to 0.003546 Gm. of Cl.

"**Assay.**—Transfer about 2 Gm. of Solution of Ferric Chloride to a flask, stopper and weigh accurately, then add 5 mils of hydrochloric acid, 25 mils of distilled water and about 3 Gm. of potassium iodide, securely stopper the flask and allow the mixture to stand for thirty minutes at a temperature of 40° C. (104° F.). Cool the liquid, dilute it with 100 mils of distilled water and then titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 10 per cent. nor more than 11 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Solution of Ferric Chloride corresponds to not less than 17.9 mils nor more than 19.7 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"An orange-brown solution with a strong styptic taste. Miscible with *water* and with *alcohol* (90 per cent.) in all proportions. Specific gravity about 1.49. Yields the *reactions* characteristic of ferric salts and of chlorides.

Yields no characteristic *reactions* for lead, copper, zinc, calcium, sodium, potassium, ammonium, or ferrous salts. On adding a clear crystal of *ferrous sulphate* to a cooled mixture of equal volumes of *sulphuric acid* and of the Strong Solution diluted with nine times its volume of *water* the crystal does not become brown, nor does a brownish-black color develop around it (limit of nitrates). *Arsenic limit* 10 parts per million. 5 millilitres diluted with 80 millilitres of *water* yield, upon the addition of an excess of *solution of ammonia,* a reddish-brown precipitate, which, when well washed and incinerated, weighs 1.42 grammes. This Solution contains 20 grammes of Iron in 100 millilitres; 110 minims contain 20 grains." *Br.*

Water and alcohol unite with it in all proportions. The British preparation (*Liquor Ferri Perchloridi Fortis*) is stronger than the U. S. official, the sp. gr. of the former being about 1.49 at 15.5° C. (60° F.), of the latter from 1.29 to 1.32 at 25° C. (77° F.). It should be remembered, however, that there is in the British Pharmacopœia, another solution of ferric chloride which is weaker; it has the sp. gr. 1.110 and is termed *Liquor Ferri Perchloridi.* (See page 636.)

From the experiments of Adrian it appears that sugar has the property when mixed in certain proportions with solution of ferric chloride of converting it partly into ferrous chloride. The alteration commences immediately on the addition of sugar, as shown by the deeper color of the liquid; after some hours potassium ferricyanide will indicate the presence of a ferrous salt, and after twenty-four hours the greater proportion of the ferric salt has undergone the change. (*B. M. S. J.,* March, 1868.)

Uses.—This preparation was brought prominently into notice by Pravaz, a surgeon of Lyons, who found that a few drops of a strong solution, injected into a blood vessel, produced coagulation of all the blood in the vessel for the extent of an inch or more. Its use as a styptic was the natural result of this observation. In arresting *hemorrhages* from cut surfaces or wounded vessels it has proved remarkably successful. It has also been found advantageous as an application to *nasal polypi, erectile tumors,* or *nævi materni* in infants, in *ulcers* about the nails, and in various cutaneous affections. Attempts have been made to cure *nævi materni* by the injection of the solution into the erectile tumor, but this proceeding is hazardous and has caused death. (*Ann. Thér.,* 1867, p. 117.) It has been used externally with asserted success in *varicose veins.* In *post-partum hemorrhage* it has been largely employed, a solution of it, varying in strength from a drachm to a half ounce to the pint, being thrown directly into the relaxed uterus. Garrett (*B. M. J.,* 1913, i) recommends the stronger solution of iron chloride *Br.* as a local application in *ringworm* of the scalp; he states that it must be applied full strength to get good results. Zeissl has used it as a local remedy in *acne rosacea.* Bourget has employed a gelatinized solution of ferric chloride in the treatment of *gastric ulcer.* (*Th. M.,* 1909, p. 353.) His solution consists of 100 grammes each of gelatin, glycerin, and water, and 50 grammes of the *liquor ferri perchloridi,* P. G.

Dose, one to five minims (0.06–0.3 mil).

Off. Prep.—Liquor Ferri Perchloridi, *Br.;* Tinctura Ferri Chloridi, *U. S.* (*Br.*); Gossypium Stypticum, *N. F.;* Tinctura Ferri Chloridi Ætherea, *N. F.;* Tinctura Ferri Citro-chloridi, *N. F.*

LIQUOR FERRI ET AMMONII ACETATIS. U. S.

SOLUTION OF IRON AND AMMONIUM ACETATE
Liq. Ferr. et Ammon. Acet. [Basham's Mixture]

(lĭ'quŏr fĕr'rī ĕt ăm-mō'nī-ī ăç-ē-tā'tĭs)

Mistura Ferri et Ammonii Acetatis, *U. S. P.* 1880.

* "Tincture of Ferric Chloride, *forty mils* [or 1 fluidounce, 169 minims]; Diluted Acetic Acid, *sixty mils* [or 2 fluidounces, 14 minims]; Solution of Ammonium Acetate, *five hundred mils* [or 16 fluidounces, 435 minims]; Aromatic Elixir, *one hundred and twenty mils* [or 4 fluidounces, 28 minims]; Glycerin, *one hundred and twenty mils* [or 4 fluidounces, 28 minims]; Distilled Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. To the solution of ammonium acetate (which must be slightly acid) add, successively, the diluted acetic acid, the tincture of ferric chloride, the aromatic elixir, and the glycerin, and lastly, enough distilled water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. This preparation must not be dispensed unless it has been recently prepared." *U. S.*

The official name of this preparation has been changed to "Liquor" in accordance with the views expressed in the 16th edition of this work, as it belongs to the class of solutions, and is not a mixture in the modern acceptation of the term. It is still, however, frequently prescribed under the old designation "*Mist. Basham.*" The formula has been improved by the addition of glycerin, which enables the solution to remain undecomposed somewhat longer. It should be borne in mind, however, that this was never intended to be a permanent solution, and in time precipitation and decomposition surely set in. Some pharmacists adopt the plan of keeping all the ingredients, except the tincture of ferric chloride and water, mixed together in advance, and when called upon to dispense the solution, to add the proper quantity of tincture and water; this saves time and enables them to dispense a clear solution.

"Solution of Iron and Ammonium Acetate is a clear, reddish-brown liquid, of a sweetish, saline and afterward slightly astringent taste; it possesses an aromatic odor. The Solution is acid to litmus. Specific gravity: about 1.039 at 25° C. (77° F.). The Solution yields a blue precipitate with potassium ferrocyanide T.S., but the addition of ammonia water produces no

precipitate. When Solution of Iron and Ammonium Acetate is heated with potassium hydroxide T.S., ammonia is evolved. Add 1 mil each of sulphuric acid and alcohol to 5 mils of the Solution and boil the mixture; ethyl acetate is formed, recognizable by its odor." *U. S.*

When freshly made, it is a transparent, bright red liquid. When cloudy, the absence of sufficient free acid is indicated. The iron is in the form of an acetate, while there is formed, as one of the products of decomposition, a small quantity of ammonium chloride, the larger proportion of ammonium acetate remaining undecomposed.

Basham's mixture is actively chalybeate, and also astringent, and is very largely used in *chronic Bright's disease.* There has arisen a popular superstition that it exercises a curative effect in nephritis, but its value is probably simply that of a hematinic and not superior to other forms of iron.

Dose, from one-fourth to one-half fluidounce (7.5–15 mils).

LIQUOR FERRI PERCHLORIDI. Br.

SOLUTION OF FERRIC CHLORIDE

(lĭ'quŏr fĕr'rī pĕr-ȼhlō'rĭ-dī)

Solution of Perchloride of Iron.

"Strong Solution of Ferric Chloride, 250 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix." *Br.*

This is one-fourth the strength of the *Liquor Ferri Perchloridi* of the Br. Pharmacopœia of 1864, which is the *Liquor Ferri Perchloridi Fortis* of the present edition. (See p. 633.) It is of the same ferruginous strength as the British Tincture of Ferric Chloride. The specific gravity of this solution is 1.110, and it may be substituted for the tincture of ferric chloride when alcohol is objectionable, as it has the same strength; it is very astringent.

Dose, from ten to thirty minims (0.6–1.8 mils), well diluted.

LIQUOR FERRI SUBSULPHATIS. U. S.

SOLUTION OF FERRIC SUBSULPHATE Liq. Ferr. Subsulph. [Solution of Basic Ferric Sulphate, Monsel's Solution]

(lĭ'quŏr fĕr'rī sŭb-sŭl-phā'tĭs)

"An aqueous solution containing basic ferric sulphate corresponding to not less than 13 per cent. nor more than 14 per cent. of Fe." *U. S.*

Solution of Subsulphate of Iron; Solution of Persulphate of Iron; Liquer hémostatique de Monsel, *Fr.;* Basisch-schwefelsaure Eisenoxydlösung, Monsel's Eisenlösung, Monselsche Eisenlösung, *G.*

* "Ferrous Sulphate, *six hundred and seventy-five grammes* [or 23 ounces av., 284 grains]; Sulphuric Acid, *sixty-five grammes* [or 2 ounces av., 128 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Add the sulphuric acid to *five hundred mils* [or 16 fluidounces, 435 minims] of distilled water in a tared capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), then add *seventy grammes* [or 2 ounces av., 205 grains] of nitric acid, and mix well. Divide the ferrous sulphate, coarsely powdered, into four approximately equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. If, after the ferrous sulphate has dissolved, the solution is of a black color, add nitric acid, a few drops at a time, with heating and stirring, until red fumes cease to be evolved. Boil the solution until it assumes a red color, and is free from nitric acid, as indicated by the test given below. During the heating add distilled water from time to time to maintain about the original volume. Lastly, add enough distilled water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter if necessary. Keep it in well-stoppered containers, in a moderately warm place (not under 22° C. or 71.6° F.), protected from light. This solution sometimes crystallizes, forming a semi-solid, whitish mass. When this occurs, the application of a gentle heat will restore the liquid condition." *U. S.*

This process is essentially that of E. R. Squibb. The object is to obtain in solution *Monsel's persulphate of Iron,* improperly so called, as it differs both in composition and in properties from the salt of iron properly named persulphate. The composition of the true persulphate (tersulphate) is $Fe_2(SO_4)_3$, and it is a neutral salt, while Monsel's persulphate has the composition $5Fe_2(SO_4)_3.Fe_2(HO)_6$, and is properly a subsalt, as it is very appropriately designated in the U. S. Pharmacopœia.

In its preparation the ferrous sulphate is converted into ferric sulphate at the expense of the nitric acid; but the sulphuric acid, mixed with the nitric, is in quantity insufficient to form the normal salt. The sesquioxide is therefore but partially saturated, and a subsalt results, having the constitution above mentioned.

J. Creuse offers the following formulas for the preparation of the solutions of *ferric sulphate* and *ferric subsulphate,* holding them to be superior to the official because they require no especial apparatus and generate no noxious vapors:

For the ferric sulphate, take of Ferrous Sulphate, in coarse powder, twelve troyounces; Sulphuric Acid two troyounces and sixty grains; Potassium Chlorate three hundred and forty-eight grains; Boiling Water twelve fluidounces. Dissolve the ferrous sulphate in the boiling water in a glass flask, or in any convenient bottle; add the sulphuric acid gradually, and, while the liquid is hot, add the potassium chlorate by small portions. When all is dissolved, filter, and complete twenty-four fluidounces. The following formula explains the reactions:

$$6FeSO_4 + 3H_2SO_4 + KClO_3 = 3Fe_2(SO_4)_3 + 3H_2O + KCl$$

For the subsulphate, take of the ingredients above enumerated, respectively, twelve troy-

ounces, one troyounce and thirty grains, three hundred and forty grains, ten fluidounces; proceed as before; evaporate to twelve fluidounces; filter. (*A. J. P.*, xliii, 169.) The solutions thus obtained contain some potassium chloride.

Properties.—The solution of ferric subsulphate is "a dark reddish-brown liquid, odorless or nearly so, of an acid, strongly styptic taste, an acid reaction and miscible with water and alcohol without decomposition. Specific gravity: about 1.548 at 25° C. (77° F.). Separate portions of an aqueous dilution of the Solution (1 in 20) yield a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in hydrochloric acid, with barium chloride T.S. Add a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of sulphuric acid and an aqueous dilution of the Solution (1 in 10); the crystal does not become brown nor does a brownish-black color develop around it (*nitric acid*). Add a few drops of freshly prepared potassium ferricyanide T.S. to 2 mils of an aqueous dilution of the Solution (1 in 20); a brown color is produced without a tinge of green or greenish-blue (*ferrous salt*).

"**Assay.**—Transfer about 1.5 Gm. of Solution of Ferric Subsulphate to a flask, stopper and weigh accurately, then add 5 mils of hydrochloric acid, 25 mils of distilled water, and 2 Gm. of potassium iodide, securely stopper the flask and allow the mixture to stand for thirty minutes at a temperature of 40° C. (104° F.). Cool the liquid, dilute it with 50 mils of distilled water, and then titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 13 per cent., nor more than 14 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Solution of Ferric Subsulphate corresponds to not less than 23.3 mils nor more than 25.1 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

A little sulphuric acid decolorizes the liquid in a considerable degree, and an excess of the same acid converts it into a white, soft, pasty solid, resembling plaster of Paris which has begun to solidify after mixture with water. This test, according to Squibb, is quite characteristic. (*N. Y. Journ. Med.*, 1860, p. 173.)

By evaporation, upon a glass surface, with a moderate heat, the solution yields ferric subsulphate or *Monsel's salt*, in the form of thin transparent scales, of a light reddish-brown color, deliquescent, and readily soluble in water. Attention was first called to the special styptic virtues of ferric sulphate by Monsel in 1852; but it was not until 1857 that he published the formula for the peculiar salt which now goes by his name, and the solution of which is the subject of the present article. (See *J. P. C.*, Sept., 1857; also *Ibid.*, Juillet, 1859.)

Uses.—In consequence of its deficiency of sulphuric acid, this salt is less irritant than the ferric sulphate, while it has at least equal, if not greater, astringency. It is very efficacious as a styptic, through its power of coagulating the blood. The solution may be applied by means of a small sponge or pencil of spun glass to the bleeding surface or vessel. It is an excellent styptic in *hemorrhage* from the stomach and bowels.

Dose, from two to five minims (0.12–0.3 mil), properly diluted, and repeated as often as necessary.

LIQUOR FERRI TERSULPHATIS. U. S. (Br.)

SOLUTION OF FERRIC SULPHATE Liq. Ferr. Tersulph. [Solution of Iron Tersulphate]

(lĭ'quor fĕr'rī tĕr-sŭl-phā'tĭs)

"An aqueous solution containing normal ferric sulphate [$Fe_2(SO_4)_3 = 399.89$], corresponding to not less than 9.5 per cent. nor more than 10.5 per cent. of Fe." *U. S.*

Liquor Ferri Persulphatis, *Br.;* Solution of Normal Ferric Sulphate, Solution of Tersulphate of Iron; Solution of Persulphate of Iron; Persulfate de Fer liquide, *Fr.;* Ferrisulfatlösung, Schwefelsaure Eisenoxydlösung, Flüssiges Schwefelsaures Eisenoxyd, *G.*

* "Ferrous Sulphate, *five hundred grammes* [or 17 ounces av., 279 grains]; Sulphuric Acid, *ninety-six grammes* [or 3 ounces av., 169 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Add the sulphuric acid to about *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of distilled water in a tared capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), then add *fifty-six grammes* [or 1 ounce av., 427 grains] of nitric acid and mix well. Divide the ferrous sulphate, coarsely powdered, into four approximately equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all of the ferrous sulphate is dissolved, if the solution has acquired a black color add nitric acid, a few drops at a time, heating and stirring until red fumes cease to be evolved, and the Solution assumes a clear reddish-brown color; then boil the liquid until it is free from nitric acid, as indicated by the test given below. During the heating add distilled water from time to time to maintain about the original volume. Lastly, add enough distilled water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter if necessary." *U. S.*

"Ferrous Sulphate, 400.0 *grammes;* Sulphuric Acid, 37.5 *millilitres;* Nitric Acid, 37.5 *millilitres;* Distilled Water, *a sufficient quantity.* Add the Sulphuric Acid to five hundred *millilitres* of the Distilled Water; dissolve the Ferrous Sulphate in the mixture with the aid of heat; mix the Nitric Acid with one hundred *millilitres* of the Distilled Water; add to this diluted acid, warmed, the solution of Ferrous Sulphate; concentrate by boiling, until, on the sudden disengagement of ruddy vapors, the

liquid ceases to be black and acquires a red color. If any ferrous salt remain in the solution, add a few drops of Nitric Acid, and boil again. When the solution is cold add, if necessary, sufficient Distilled Water to produce five hundred and fifty *millilitres*." *Br.*

The strength of this solution was increased in the U. S. Pharm. VIII. The U. S. P. (1890) required a strength equivalent to 8 per cent. of metallic iron, the present Pharmacopœia requires about 10 per cent. The ferrous sulphate is preferably in clear crystals, meaning by this "not effloresced," because when the crystals are coated with a whitish powder they have lost water of crystallization, and the proportion of iron present is variable. The nitric acid in the process gives up enough of its oxygen to convert it entirely into ferric sulphate, and the effervescence is owing to the escape of nitrogen dioxide; this becomes red nitrogen tetroxide by contact with the air. The conversion of the ferrous salt into ferric salt is incomplete until the effervescence ceases, and the color, instead of black, as it was at first, has become reddish-brown. Indeed, in order to convert the whole into ferric sulphate it is necessary to continue the heat until nitrous odor ceases to be evolved and thus the entire absence of nitric or nitrous acid from the solution is insured. In consequence of the higher oxidation of the iron the sulphuric acid of the sulphate is insufficient to saturate it. Enough sulphuric acid, therefore, is added to meet this demand. The process is completed by adding enough water to make a definite weight. The U. S. and British formulas are the same in principle.

Properties.—The solution, prepared according to the U. S. formula, is "a yellowish-brown liquid, almost odorless, having an acid, strongly styptic taste, and an acid reaction; it is miscible with water and alcohol. Specific gravity: about 1.432 at 25° C. (77° F.). Separate portions of an aqueous dilution of the Solution (1 in 20) yield a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in hydrochloric acid, with barium chloride T.S. Add a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of sulphuric acid and an aqueous dilution of the Solution (1 in 10); the crystal does not become brown, nor does a brownish-black color develop around it (*nitric acid*). Add a few drops of freshly prepared potassium ferricyanide T.S. to 2 mils of an aqueous dilution of the Solution (1 in 20); a brown color is produced without a tinge of green or greenish-blue (*ferrous salt*).

"**Assay.**—Transfer about 1.5 Gm. of Solution of Ferric Sulphate to a flask, stopper and weigh accurately, then add 5 mils of hydrochloric acid, 25 mils of distilled water, and 2 Gm. of potassium iodide, securely stopper the flask and allow the mixture to stand for thirty minutes at a temperature of 40° C. (104° F.). Cool the liquid, dilute it with 50 mils of distilled water and then titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 9.5 per cent. nor more than 10.5 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Solution of Ferric Sulphate corresponds to not less than 17 mils nor more than 18.8 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"A dark-red solution. Inodorous; very astringent. Miscible in all proportions with *alcohol* (90 per cent.) and *water*. Specific gravity about 1.441. Yields the *reactions* characteristic of ferric salts and of sulphates. Yields no characteristic *reactions* for ferrous salts. *Arsenic limit* 5 parts per million. 5 millilitres diluted with 80 millilitres of *water* yield, upon the addition of excess of *solution of ammonia*, a precipitate which, when well washed and incinerated, weighs 1.04 grammes." *Br.*

Procter found that a preparation containing 120 grains of sesquioxide to the fluidounce is apt to deposit the anhydrous sulphate on standing.

Uses.—This solution, though powerfully astringent, is too irritant for general use. The chief employment of it is in making other ferruginous preparations in which the ferric hydroxide is wanted, and it should always be kept on hand for the quick preparation of the antidote to arsenic.

LIQUOR FORMALDEHYDI. U. S., Br.

SOLUTION OF FORMALDEHYDE Liq. Formaldehyd.

(lĭ'quŏr fōrm-ăl-dē-hȳ'dī)

"An aqueous solution containing not less than 37 per cent. by weight of CH_2O or H.CHO (30.02), with varying amounts of methyl alcohol to prevent polymerization. Preserve it in a moderately warm place, protected from light." *U. S.* "Solution of Formaldehyde is an aqueous solution containing in 100 millilitres not less than 36 and not more than 38 grammes of formaldehyde, CH_2O. Formaldehyde may be obtained by the limited oxidation of methyl alcohol." *Br.*

Formol, Formalin; Soluté d'Aldehyde Formique, *Fr.*; Formaldehydum solutum, *P. G.*; Formaldehydlösung, *G.*; Formol, *Sp.*

Preparation.—*Formaldehyde* was first prepared in 1868 by Hofmann by passing a mixture of air and methyl alcohol vapor over heated platinum, and it is still practically obtained only from the oxidation of methyl alcohol. This is accomplished in "formaldehyde lamps," or on a larger scale in forms of apparatus, such as that described by G. L. Taylor (*A. J. P.*, 1898, 195) as follows: The methyl alcohol to be converted is contained in a circular steel tank, capable of resisting heavy pressure; in the bottom of this tank is placed a coil of copper pipe into which steam at a high temperature is admitted; by this means the alcohol in the tank is boiled, and the resulting vapor is confined until a pressure of 75 to 80 pounds is reached, when it is

allowed to escape into an air-mixer. This mixer is so constructed that an exactly determined quantity of air can be intimately combined with the methyl alcohol vapors. From the mixer the combination of air and vapor passes with great force and velocity through a fine tube into the converter, which has been brought to a dull red heat. This converter consists of two concentric copper tubes, the space between which is filled with broken coke or other material of a similar nature. The inner tube is finely perforated with many small holes. The alcohol vapor is admitted into this inner tube, and, escaping through the perforations, is oxidized by coming in contact with the heated coke and the copper surface of the outer tube. The gases so produced pass into the condenser, which consists of a cylindrical tank—which may be of copper; it contains a copper pipe, through which circulates a refrigerating mixture capable of reducing the temperature in the tank to about 0° C. (32° F.), at which temperature formic aldehyde condenses into a clear mobile liquid, which boils at –21° C. (–5.8° F.), and which polymerizes to paraformaldehyde at 20° C. (68° F.). After a certain process of purification, enough water is added to the formaldehyde so obtained to form a 40 per cent. solution; but this solution is not, strictly speaking, a solution of formaldehyde, as the pure formaldehyde polymerizes the moment the temperature rises above 20° C. (68° F.), and it is this property which renders the addition of water or alcohol necessary. Hence the aqueous solution of formaldehyde probably contains some paraformaldehyde and some unconverted methyl alcohol is always present which is allowed to remain because of the preservative effect it has in preventing polymerization. This change which sometimes occurs in commercial solutions of formaldehyde during the winter months is accompanied by the deposition of a white precipitate sometimes occupying a bulk equal to one-half of the original liquid and when it has occurred the only method of restoration is to acidify with sulphuric acid and redistil the liquid. The commercial products are always aqueous solutions, the common strength being the 37 per cent. solution; a 50 per cent. solution is not permanent.

Properties.—Solution of formaldehyde or "formaldehyde," as it is commonly called, is officially described as "a clear, colorless or nearly colorless liquid, having a pungent odor and a caustic taste; its vapor acts as an irritant upon mucous membrane. It is miscible with water or alcohol. On long standing, especially in the cold, Solution of Formaldehyde sometimes loses its transparency, the cloudiness being due to the separation of paraformaldehyde. Dilute 5 mils of Solution of Formaldehyde with 25 mils of distilled water and add 3 mils of silver ammonium nitrate T.S.; metallic silver is produced either in the form of a finely divided gray precipitate or as a bright metallic mirror adhering to the sides of the test tube. Add 2 drops of Solution of Formaldehyde to 5 mils of sulphuric acid in which a little salicylic acid has been dissolved, and warm the liquid very gently; a permanent deep red color appears. Not more than 1 mil of normal potassium hydroxide V.S. is required to neutralize 20 mils of Solution of Formaldehyde, to which 2 drops of phenolphthalein T.S. have been added (*free acids*).

"**Assay.**—Transfer 3 mils of Solution of Formaldehyde to a tared flask containing 10 mils of distilled water, tightly stopper and weigh accurately. Add to the contents of the flask 50 mils of normal potassium hydroxide V.S., and follow this immediately but slowly through a small funnel with 50 mils of solution of hydrogen dioxide which has previously been rendered neutral to litmus with potassium hydroxide. Now heat the mixture cautiously on a water bath for five minutes, shaking occasionally during this time; allow the mixture to cool, rinse the funnel and sides of the flask with distilled water and, after allowing it to stand thirty minutes, titrate with normal sulphuric acid V.S., using litmus T.S. as indicator. It shows not less than 37 per cent. of CH_2O, correction being made for free acid if present.

"Each mil of normal potassium hydroxide V.S. corresponds to 0.03002 Gm. of CH_2O. Each gramme of Solution of Formaldehyde corresponds to not less than 12.3 mils of normal potassium hydroxide V.S." *U. S.*

"A colorless liquid with a characteristic, pungent odor. Neutral or slightly acid to *litmus*. Miscible with *water* and with *alcohol* (90 per cent.) in all proportions. Caustic when applied to the skin. Specific gravity 1.079 to 1.081. Yields, when evaporated to dryness, a whitish, amorphous residue which leaves no appreciable ash on incineration. Yields with *solution of silver ammonio-nitrate* a precipitate of metallic silver. On the addition of 2 drops of the Solution to 5 millilitres of *sulphuric acid*, in which a little *salicylic acid* has been previously dissolved, a deep red coloration is produced. When 1 millilitre is mixed with 10 millilitres of *N/10 solution of iodine*, the mixture nearly decolorised with *solution of sodium hydroxide* and warmed, no yellow, crystalline precipitate is produced (absence of acetone). Diluted with four times its volume of *water* it yields no characteristic *reactions* for iron, copper lead, calcium, chlorides, or sulphates. Contains in 100 millilitres not less than 36 and not more than 38 grammes of formaldehyde, CH_2O, as determined by the following process:—To 50 millilitres of *N/1 solution of sodium hydroxide* add 3 millilitres of Solution of Formaldehyde and 50 millilitres of *solution of hydrogen peroxide* and warm on a water-bath; similarly mix 50 millilitres of *N/1 solution of sodium hydroxide* with 50 millilitres of *solution of hydrogen peroxide* and warm on a water-bath. When the reactions are complete and all effervescence has ceased, add a few drops of *solution of phenolphthalein* to each mixture and titrate with *N/1*

solution of sulphuric acid. The difference between the two titrations is not less than 36 and not more than 38 millilitres." *Br.*

Formaldehyde may be determined in aqueous solutions by treatment with excess of standard ammonia, which converts it into hexamethylenamine. The excess of ammonia may then be titrated with standard acid. The mixture of the formaldehyde solution and ammonia should stand for at least twelve hours. This method, however, has not been found in practice to be as accurate as the hydrogen dioxide method, which was therefore chosen by the Revision Committee as the basis of the official assay process. Because of the use of formaldehyde as a preservative of milk and food products the detection of small amounts of it is a matter of great importance. Several of the tests proposed are primarily applicable to milk only, being based on reactions which take place in the presence of milk proteids, so that if these tests are to be applied in testing other liquids for the presence of formaldehyde, the material must be mixed with an equal quantity of milk which has been shown previously to be free from formaldehyde. The principal tests may be divided into two groups, those in which a colored zone is obtained at the junction of two liquids, one of which has been superimposed upon the other, and those in which a color reaction is obtained in the body of the liquid tested. The first group includes the resorcinol-sulphuric acid test, the phenol-sulphuric acid test, and the sulphuric acid test of Hehner (carried out in the presence of milk). The method of application of the two tests first mentioned is as follows: To 5 mils of the liquid to be tested, one or two drops of a one per cent. aqueous solution of phenol or resorcinol are added, and this liquid is then allowed to flow gently down the inside of the test tube containing 2 or 3 mils of the sulphuric acid so as to form a layer above the acid without mixing. In the presence of formaldehyde a rose-colored zone is produced in extreme dilution, or in more concentrated solutions an opaque pinkish zone above the rose-colored one. In the Hehner test, the liquid to be tested is mixed with an equal volume of formaldehyde-free milk, and this mixture is allowed to flow down the inside of the test tube upon 2 or 3 mils of commercial sulphuric acid containing a trace of ferric chloride. A violet zone is formed in the presence of formaldehyde. The general color tests constituting the second group of tests are the phenylhydrazine test with its modifications, the phloroglucinol test, the resorcinol-soda test, and the hydrochloric acid test. (A full discussion and comparison of these tests by C. H. LaWall will be found in *Am. Drug.*, 1905, vol. xlvii, p. 33.)

The foregoing tests are all group tests for aldehydes and positive results will be obtained in the presence of furfurol, vanillin, and many other aldehydic bodies. The best specific test given by formaldehyde only is that of Rimini, and is carried out as follows: To 10 mils of the clear liquid or distillate is added 0.05 gramme phenylhydrazine hydrochloride followed by 3 drops of a 5 per cent. aqueous solution of sodium nitroprusside, and, finally, by 1 mil (or an excess) of a 10 per cent. sodium hydroxide solution. In the presence of formaldehyde a blue or greenish-blue color is immediately produced which, however, quickly changes to yellow and finally to red.

The test is so sensitive as to detect the substance in a solution containing but one drop of commercial formaldehyde solution in five gallons of water.

A. B. Lyons (*Proc. A. Ph. A.*, 1905, 326) proposes the use of *beef peptone* in place of milk (except when milk is under investigation) in Hehner's test (see above). He also suggests the use of morphine and sulphuric acid as a test for formaldehyde. (*Proc. A. Ph. A.*, 1905, 329.)

Uses.—Formaldehyde was introduced as a disinfectant by Trillat in 1888. It is remarkable among germicidal agents for the fact that its action in solution is less powerful than as a vapor. Its solutions are about equivalent in germicidal activity to those containing the same percentages of phenol. Burgess (*L. L.*, 1900, i, p. 1797) found that a 2 per cent. solution would kill the *B. coli communis* in five minutes and Slater and Rideal found that it required 50 minutes for a one per cent. solution to destroy various non-sporulating micro-organisms. Its action as an antiseptic, however, far exceeds that of phenol. In Slater and Rideal's experiments one part in five thousand absolutely inhibited, and one in twenty thousand greatly restrained the growth of bacteria. As regards the effects of formaldehyde vapor, it has been shown that as little as one part in three thousand parts of air will destroy many bacteria and, according to Kenwood, one or two per cent. will rapidly disinfect all surfaces. It should be remarked in this connection that the penetrating power of formaldehyde has been usually overestimated and that bundles of clothing or similar material are not effectually disinfected by such strengths of the gas.

Formaldehyde is an intense local irritant both to mucous membranes or if in sufficient concentration, to the skin. In strong solution it precipitates albumen or gelatin, but very minute quantities are asserted to prevent the coagulation of albumen by heat. When injected into the circulation in such dilutions as not to precipitate the proteins of the blood, or after its absorption through the gastro-intestinal mucosa, it exercises relatively slight effects on the vital functions. According to McGuigan (*J. A. M. A.*, 1914, lxii, p. 984) large quantities lower the blood pressure by a direct action upon the heart and vessel walls. Fleig states that it causes contraction of the renal vessels. It is rapidly oxidized in the system and appears in the urine as formic acid, so that after the administration of even relatively large doses no formaldehyde can be found in the excretions.

Formaldehyde is used in medicine chiefly for its disinfectant properties. Because of its local irritant influence it is rarely of service as a surgical application to the living body. It is occasionally used for the disinfection of surgical instruments and apparatus. For this purpose the vapor is more efficient than the solution. The most important use of formaldehyde is for the disinfection of rooms and various objects like books which might be injured by steam. Although it has a powerful effect on some forms of organic matter, things which are likely to come in contact with patients suffering from infectious diseases, such as clothing and the decorations in the sick room, are not injured by disinfectant strengths. Because of its affinity for ammonia and for hydrogen sulphide it has strong deodorizing properties. Various methods for the vaporization of formaldehyde are used in room disinfection; these include (1) direct generation by oxidizing methyl alcohol; (2) spontaneous evaporation of a solution sprinkled around the room; (3) evaporation of the official solution by means of heat; (4) vaporization of the official solution by oxidizing agents; and (5) decomposition of its polymer known as paraform. The first of these has been largely abandoned because of its cumbersomeness and the uncertainty of amount, the second because of its inefficiency and injurious effect upon the operators. The decomposition of paraform by heat is a convenient method for disinfecting small spaces, such as boxes containing surgical appliances, or closets, but is too expensive for general use; moreover, the presence of considerable amounts of aqueous vapor in the air is essential for best results with formaldehyde, and in most of the apparatuses using paraform insufficient provision is made for this. The method of evaporating aqueous solutions of formaldehyde with heat is the basis of a number of efficient apparatuses, but it is doubtful whether these have any real advantage over the cheap and handy method of volatilizing by means of oxidizing agents. The substances which have been used for the latter service include potassium permanganate, quick lime, barium peroxide, and sodium dichromate. The method recommended by the Pennsylvania State Board of Health, Dixon (*A. J. P.*, July, 1912) is as follows: For a thousand cubic feet of air space, one pint of the official solution of formaldehyde and eight ounces of potassium permanganate. Place the potassium permanganate in a bucket with at least ten times the capacity of the amount of disinfectant. Pour the formaldehyde on the permanganate. Eighty per cent. of the formaldehyde is liberated in the first five minutes. Doerr recommends the proportion of one part each of potassium permanganate, formaldehyde solution, and water. Hall and Roberts assert that seven parts of potassium permanganate to ten of formaldehyde solution is the most economical; this gives a liberation of 63 per cent. of the total formaldehyde. If water is added the percentage of liberation is lower, but the water is advantageous in aiding the disinfectant properties. It should be remembered that with careless use there is a possibility of setting fire to the room. In 1914, owing to the scarcity of potassium permanganate caused by the European war, a method was devised by LaWall (*J. A. M. A.*, 1914, lxiii, 1025) in which sodium dichromate takes the place of potassium permanganate. Notwithstanding some criticism of this process, as destroying a larger amount of the formaldehyde than the potassium permanganate method, tests made by the Pennsylvania Health Department bacteriologist, working under conditions such as are actually encountered in practical disinfection work, show all bacteria to be killed when the directions are carefully followed.

Inhalations of formaldehyde vapors have been tried in the treatment of pulmonary disorders, notably *phthisis*, with the idea of direct destructive action upon the bacteria, but they are so irritant to mucous membranes that the treatment has done more harm than good. Formaldehyde is also of service for the purpose of hardening the skin and of stopping excessive sweating in various forms of *hyperidrosis*. For this use the official solution should be diluted with from one to three parts of water. It is used in pharmacy for hardening gelatin capsules. (See page 511.)

Although its physiological action is comparatively slight, yet when swallowed it is a dangerous poison on account of its local irritant effects. The symptoms of formaldehyde poisoning are immediate severe abdominal pains with blood-stained vomiting, general collapse often with loss of consciousness, and albuminous, bloody or suppressed urine. Out of ten cases collated by McLoughlin (*Cleveland Med. Journ.*, 1909) three ended fatally. The smallest fatal dose of which we have any knowledge is the case reported by Eli (*J. A. M. A.*, liv) in which "a few drops of a 40 per cent. solution of formaldehyde" killed a three year old child with symptoms of edema of the larynx. The ordinarily fatal dose for an adult is about three fluidounces of the official solution. The diagnosis is usually easy from the odor of formaldehyde in the vomitus. The treatment requires an immediate evacuation of the stomach, the use of dilute ammonia water as an antidote, subsequently demulcents and symptomatic remedies as they may be indicated.

Formaldehyde is also used to harden gelatin capsules. (See p. 511.)

Festiform is a solution of formaldehyde solidified by the addition of soap. *Autan* is a mixture of paraform and barium peroxide which in the presence of water liberates formaldehyde gas. *Formysol* is a formalized soft soap as is also veroform. *Lysoform* is another saponaceous mixture containing formaldehyde.

Off. Prep.—Liquor Formaldehydi Saponatus, *Br.*

LIQUOR FORMALDEHYDI SAPONATUS. Br.

SOLUTION OF FORMALDEHYDE WITH SOAP

(lĭ'quŏr förm-ăl-dē-hī'dī să-pō-nā'tŭs)

"Soft soap, 400 *grammes;* *Alcohol* (90 per cent.), 300 *millilitres;* Solution of Formaldehyde, 200 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve the Soft Soap in the Alcohol; add the Solution of Formaldehyde and sufficient Distilled Water to produce the required volume." *Br.*

This solution was introduced into the British Pharm., 1914, for the first time. It is intended to be used externally and for surgical cleansing.

LIQUOR HYDRARGYRI NITRATIS ACIDUS. Br.

ACID SOLUTION OF MERCURIC NITRATE

(lĭ'quŏr hȳ-drär'gy-rī nī-trā'tĭs ăç'ĭ-dŭs)

Liquor Hydrargyri Nitratis, *N. F.;* Solution of Mercuric Nitrate; Solution of Nitrate of Mercury; Solution of Pernitrate of Mercury; Liquor Hydrargyri Nitrici Oxydati; Azotate Mercurique liquide, *Fr. Cod.;* Deutazotate (Pernitrate) de Mercure liquide, *Fr.;* Mercurnitratlösung, Quecksilberoxydnitratlösung, Flüssiges Salpetersaures Quecksilberoxyd, *G.*

"Mercury, 120 *grammes;* Nitric Acid, 150 *millilitres;* Distilled Water, 45 *millilitres.* Mix the Nitric Acid with the Distilled Water in a tared flask; dissolve the Mercury in the mixture without the application of heat; then boil gently until the Solution weighs three hundred and sixty *grammes.* Preserve it in a stoppered bottle not exposed to the light." *Br.*

The U. S. P. IX dismissed this solution, but the British Pharm. retained it. The National Formulary IV (see Part III) introduced the solution which was official in the U. S. P. VIII which was as follows:

"Red Mercuric Oxide, *forty grammes* [or 1 ounce av., 180 grains]; Nitric Acid, *forty-five grammes* [or 1 ounce av., 257 grains]; Distilled Water, *fifteen grammes* [or 231 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the Nitric Acid with the Distilled Water, and dissolve the Red Mercuric Oxide in the mixture. Keep the product in glass-stoppered bottles." *U. S. VIII.*

In the British process, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid mercuric nitrate, which is brought to a determinate bulk by evaporation. The proportion of nitric acid is sufficient not only to form mercuric nitrate, but also to furnish a large excess of acid.

Properties.—Solution of mercuric nitrate is a clear, nearly colorless, heavy liquid, having a faint odor of nitric acid, and a strongly acid reaction. "Specific gravity about 2.0. Yields no characteristic *reaction* for mercurous salts." *Br.*

Mercuric nitrate, the salt present in this preparation, can be obtained in large crystals of the composition $Hg(NO_3)_2 + 4H_2O$, when its solution is allowed to evaporate slowly over sulphuric acid. The same salt, which is very deliquescent, is obtained as a crystalline magma by adding strong nitric acid to the concentrated solution.

Uses.—This preparation is used as a caustic application to *cancers, lupus, ulcerations* of the *cervix, chancres,* etc. When a very free use is desired, it may be applied to the diseased surface by a camel's-hair brush, or preferably by a brush made of spun glass; usually, however, the application is made with a glass rod, or a match or similar fragment of wood. In *acne* and *boils,* a drop proportioned in size to the pustule applied to the apex is sometimes of service. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic. It is not used internally.

LIQUOR HYDRARGYRI PERCHLORIDI. Br.

SOLUTION OF MERCURIC CHLORIDE

(lĭ'quŏr hȳ-drär'gy-rī pĕr-ȼhlō'rĭ-dī)

Liquor Hydrargyri Bichloridi; Solution of Bichloride of Mercury; Solution of Corrosive Sublimate; Sublimatlösung, *G.*

"Mercuric Chloride, 1 *gramme;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve. This Solution should be kept protected from light. 100 millilitres contain 0.1 gramme of Mercuric Chloride; 110 minims contain 1/10 grain." *Br.*

This solution may be used as affording a convenient method of exhibiting corrosive sublimate. The ammonium chloride formerly used (Br. Ph., 1885) to aid in dissolving the mercuric chloride has been omitted in the process of the Br. Ph., 1914.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

LIQUOR HYDROGENII DIOXIDI. U. S. (Br.)

SOLUTION OF HYDROGEN DIOXIDE Liq. Hydrog. Diox. [Solution of Hydrogen Peroxide, Aqua Hydrogenii Dioxidi, U. S. P. VIII]

(lĭ'quŏr hȳ-drŏ-gē'nĭ-ī dī-ŏx'ĭ-dī)

"An aqueous solution containing not less than 3 per cent. by weight of H_2O_2 (34.02), corresponding to not less than 10 volumes of available oxygen. Preserve it in a cool place protected from light. Upon removing the stopper from the bottle, not more than a slight pressure should be observed." *U. S.* "Solution of Hydrogen Peroxide is an aqueous solution of hydrogen peroxide, H_2O_2, prepared by the interaction of water, barium peroxide, and a dilute mineral acid, at a temperature below 10° C. (50° F.)." *Br.*

Liquor Hydrogenii Peroxidi, *Br.,* Solution of Hydrogen Peroxide; Oxygenized Water, Oxygen Hydrate; Péroxide d'Hydrogène; Solutéofficinal d'eau oxygénée au dixiéme, *Fr. Cod.;* Wasserstoffhyperoxyd, Wasserstoffhyperoxidlösung, *G.;* Acqua ossigenata, *It.;* Agua oxigenada, *Sp.*

The extended use of this preparation, which was discovered by Thenard in 1818, has earned for it a place in the U. S. and British Pharmacopœias. It consists of water in which, by the presenting to it of oxygen in a nascent state, an additional atom of this element has combined with the hydrogen, forming the dioxide $(HO)_2$, or H_2O_2.

The U. S. P., 1890, process (see *U. S. D.*, 18th edition, p. 214) consisted in the decomposition of barium dioxide by phosphoric acid, barium phosphate being thrown down as a precipitate, hydrogen dioxide being found dissolved in the supernatant aqueous liquid; the barium phosphate is filtered out, and any trace of barium salt is finally removed by the cautious addition of sulphuric acid, which precipitates it as insoluble barium sulphate; the very fine precipitate which usually passes through the pores of filter paper is caught and held on the filter by the starch, and the clear solution may be adjusted to contain 3 per cent., *by weight*, of absolute hydrogen dioxide by assay.

Commercially it is usually made by a process essentially the same as that given above, the phosphoric acid being regenerated from the precipitate of barium phosphate by the addition of sulphuric acid which converts it into insoluble barium sulphate with the liberation of almost the original amount of phosphoric acid used. Another method is also used in which hydrofluoric acid is employed. This yields the comparatively insoluble barium fluoride as a by-product and the hydrofluoric acid may be regenerated from this also by the use of sulphuric acid. On the large scale it is necessary to reduce the temperature of the reaction by refrigeration of some kind in order to get any where near the full theoretical yield from the barium dioxide used. One of the important points is the preliminary hydration of the barium dioxide which is accomplished by allowing the dioxide to stand in contact with an excess of water until it attains a creamy consistence.

According to Crismer, a pure solution may be made by dissolving barium peroxide in a slight excess of diluted hydrochloric acid (sp. gr. 1.10), and shaking the solution with an equal volume of ether. The ethereal layer is separated and shaken with a little water, which will take up most of the hydrogen peroxide, after the separation of which the ether is again shaken with the above separated solution of barium peroxide, and then with water as before. These operations are repeated five or six times. It is possible in this way to obtain solutions containing from 0.8 to 0.9 per cent. of the peroxide, which are perfectly neutral and free from foreign substances. (*Bull. Soc. Chim.*, 1891, 24.) Horlin (*Zeit. angew. Chem.*, 1902, 600) prepares the solution by adding at a low temperature with caution, sodium dioxide to a solution of hydrofluoric acid; hydrogen dioxide and sodium fluoride are produced, the solution is treated with aluminum fluoride, which results in producing the insoluble double fluoride of aluminum and sodium, which separates out. The official Solution is strong enough for most practical uses, for, although it can readily be made stronger, the difficulties of preserving it largely increase with its increased strength, and hence the Committee of Revision wisely fixed the standard at *ten volumes of available oxygen*. The British Pharmacopœia requires that the Solution shall indicate a yield of from *nine to eleven volumes* of oxygen when tested by the nitrometer test. (See page 644.)

Properties.—Hydrogen dioxide was prepared by Regnault in a nearly pure state. As thus procured, it is a colorless liquid of a fluid consistence, of the sp. gr. 1.452, remaining liquid at zero, beginning to give out oxygen when heated above 15.5° C. (60° F.), and at a higher heat rapidly and sometimes explosively resolved into water and oxygen. But when diluted with water, with which it unites in all proportions, it is not decomposed under 37.7° C. (100° F.). It may be evaporated *in vacuo* at a gradually increasing temperature, a nearly pure hydrogen dioxide coming over at about 84° C. (183.2° F.). Wolffenstein states that he has prepared, after repeated fractioning, hydrogen peroxide (99.1 per cent.). (See *Ber. d. Chem. Ges.*, 1894, 3307. See also Schiloff's process, *Chem. News*, 1896, 38.) Crystallized hydrogen dioxide has been made by W. Staedel by applying a freezing mixture to a very strong solution of the dioxide, and collecting the separated columnar crystals; it is a very active body, being decomposed with explosive violence on coming in contact with manganese dioxide. (*Ph. Centralh.*, 1902, 546.) The great facility with which it parts with oxygen renders it a powerful oxidizer; and the simple contact with various substances, as platinum, gold and silver, causes it to be resolved into oxygen and water. On the contrary, certain other substances, even though ordinarily evincing a strong affinity for oxygen, as phosphorus, for example, are unaffected by it, and there are a number of bodies which have the property not only of being unaffected by it, but of restraining its oxidizing influence on other bodies, while some salts, like silver oxide, are actually reduced by it. Traces of impurities modify the stability of hydrogen dioxide; acids increase, alkalies decrease, its stability. Some manufacturers add a certain proportion of oxalic acid to the solution of hydrogen dioxide to raise the apparent value of the product, as shown by the permanganate assay; for a method of detecting this fraud, see a paper by G. Arth (*D. C.*, 1902, p. 141).

The official solution is described as "a colorless liquid, odorless or having an odor suggesting ozone, slightly acid to the taste and producing a peculiar sensation and froth in the mouth; prone to deteriorate upon keeping or upon protracted agitation, and rapidly decomposed by contact with many oxidizing as well as reducing substances. If the stopper of the bottle is coated with paraffin or replaced by a

pledget of purified cotton, deterioration is retarded. When exposed to the air at the ordinary temperature or when heated on a water bath at a temperature not exceeding 60° C. (140° F.), the solution loses chiefly water. When rapidly heated, it frequently decomposes suddenly. Solution of Hydrogen Dioxide is acid to litmus. Shake 1 mil of Solution of Hydrogen Dioxide with 10 mils of distilled water containing 1 drop of diluted sulphuric acid, and add 2 mils of ether. The subsequent addition of a drop of potassium dichromate T.S. produces a blue color in the aqueous layer. Upon agitation, this blue color passes into the ethereal layer. Not more than 0.03 Gm. of solid residue remains on evaporating 20 mils of the Solution to dryness on a water bath (*non-volatile matter*). It requires not more than 2 mils of tenth-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator, to neutralize 25 mils of Solution of Hydrogen Dioxide (*free acid*). Add 1 mil of ammonia water to 1 mil of the Solution and evaporate the liquid to dryness on a water bath; the residue meets the requirements of the Test for arsenic (see Part III, Test No. 1). Evaporate 1 mil of the Solution to dryness on a water bath and dissolve the residue in 10 mils of distilled water containing 1 mil of diluted hydrochloric acid; the liquid does not respond to the Test for heavy metals (see Part III, Test No. 3). Evaporate 50 mils of the Solution, previously rendered alkaline by the addition of sodium hydroxide T.S., to dryness on a water bath and transfer the dry residue to a platinum crucible. Moisten the residue with sulphuric acid, and cover the crucible with a watch glass, the convex side of which is coated with a thin layer of wax which is afterwards scratched so as to expose the glass. Cool the watch glass by placing water in the concave side and standing in this a small beaker which must be kept filled with cold water. Now heat the crucible and contents on a water bath for one hour; the surface of the watch glass after being cleaned shows no sign of corrosion (*hydrofluoric acid*). The addition of 2 drops of diluted sulphuric acid to 10 mils of the Solution produces no turbidity or precipitate within ten minutes (*barium*). Add 4 drops of sodium acetate T.S. to 10 mils of the Solution and follow with 4 drops of calcium chloride T.S.; no turbidity or precipitate is produced within ten minutes (*oxalic acid*). Shake out 100 mils of Solution of Hydrogen Dioxide in a separator with a mixture of three volumes of chloroform and two volumes of ether, using 50 mils, 25 mils, and 25 mils, respectively, and evaporate the combined solutions to dryness at room temperature in a tared glass dish. A residue may be obtained which weighs not more than 0.04 Gm. (*limit of preservative*)." *U. S.*

"A colorless and odorless liquid. Taste slightly acid. Decomposed by heat into water and oxygen. On adding a few drops to 10 millilitres of *water* mixed with a drop of *solution of potassium chromate*, 10 drops of *diluted sulphuric acid*, and 2 millilitres of *ether*, a blue layer appears between the ethereal and the aqueous liquid, and, after shaking, the *ether* also becomes blue. 2 millilitres vigorously shaken in a brine-charged nitrometer with 4 millilitres of *solution of copper ammonio-sulphate* liberate, at 15.5° C. (60° F.), and normal pressure, not less than 18 and not more than 22 millilitres of oxygen, corresponding to about 10 volumes of available oxygen in 1 volume of the Solution. 25 millilitres require for neutralisation not more than 2.5 millilitres of *N/10 solution of sodium hydroxide, solution of methyl orange* being used as indicator (limit of acidity). Yields no characteristic *reactions* for barium. Evaporated to dryness on a water-bath, not more than 1 per cent. of solid residue remains." *Br.*

"**Assay.**—Dilute about 2 Gm. of Solution of Hydrogen Dioxide, accurately weighed, with 20 mils of distilled water, then acidulate it with 20 mils of diluted sulphuric acid and titrate with tenth-normal potassium permanganate V.S. It shows not less than 3 per cent. of H_2O_2.

"Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.0017008 Gm. of H_2O_2, or to 0.0008 Gm. of oxygen. Each gramme of Solution of Hydrogen Dioxide corresponds to not less than 17.6 mils of tenth-normal potassium permanganate V.S." *U. S.*

Charles Rice suggests improvements in the method of assay which are practical. (See *Am. Drug.*, 1892, 30.) F. X. Moerk has proposed a rapid and effective method of assaying this solution (see *A. J. P.*, 1893, 65); J. F. Brown confirmed the value of Moerk's method (*P. J.*, 1896, 271). *Solution of hydrogen dioxide should be kept in a cool place, and not too tightly stoppered.* (A plug of absorbent cotton is often used.) Neglect of these precautions, particularly in hot weather, will be likely to result in an explosion and fracture of the bottle containing it, due to a brisk evolution of oxygen in a confined space, on account of the increased temperature.

Hydrogen dioxide solution is usually preserved at the present time by the use of acetanilid or some other equally efficacious agent for retarding its decomposition. The presence of acetanilid was first called attention to in pharmaceutical literature by LaWall (*A. J. P.*, 1906, p. 582). Boroglycerin, caffeine, and other substances have also been used for the purpose. When acetanilid is used the solution upon standing for some time occasionally acquires a disagreeable odor due to the formation of nitrobenzol and other decomposition derivatives of the acetanilid. The amount of acetanilid used as a preservative is very small, being about 0.05 per cent. A study of the effect of various preservatives was reported by A. M. Glover (*A. J. P.*, 1913, p. 538), who found acetanilid to be the best of all that were tried.

It has been claimed that its deterioration is often due to the alkalinity of the glass bottles

in which it is stored, and that if alkali-free glass containers be used it will keep for extended periods without a preservative.

Jordan (*J. A. Ph. A.*, 1913, ii, p. 344) finds that solutions of hydrogen dioxide kept in bottles stoppered with cotton, instead of a cork, retain their activity very much better, he believes, on account of the evaporation of the water. He also found that bottles protected from the light retained their activity better than those exposed to the light. Most of the samples examined were below pharmacopœial strength. One contained as little as 0.24 per cent. of H_2O_2, but the majority of them ranged from 2.5 to 3 per cent.

Uses.—Hydrogen peroxide in solution undergoes a slow process of reduction liberating a portion of its oxygen. Certain organic matters, however, among which may be mentioned pus and blood, exercise a powerful catalyzing action so that the oxygen is given off very rapidly. Evidently this nascent oxygen must have a powerful oxidizing effect and thereby destroy many forms of organic matter. It should be noted that in the presence of these reducing agents the antibacterial powers of the drug are greatly reduced. As long as there is effervescence caused by the application of hydrogen dioxide to a wound there is no great destruction of bacteria. Upon the system generally hydrogen peroxide does not, and cannot, exert any physiological action, because it cannot exist in the blood.

The most important use for this agent is as an antibacterial agent. The germicidal activity of hydrogen peroxide is generally greatly overestimated. Although in relatively dilute solution it will eventually destroy many of the pathogenic micro-organisms, its action is extremely slow, unless the solution be fairly concentrated. Gifford (*N. Y. M. R.*, 1888) found that a neutral solution containing 15 per cent. by volume of H_2O_2 (therefore stronger than the official solution) would destroy anthrax spores after five minutes' exposure, and pus cocci in one minute, but that the same solution when diluted with four parts of water did not kill the pus cocci after thirty minutes. Traugott found that 1 per cent. by weight killed typhoid bacilli in five minutes and staphylococci in fifteen to thirty minutes. In the presence of organic matter this compound is so rapidly broken down that it is even less efficient; as pointed out by Gifford, its germicidal action does not depend upon the liberated oxygen, but upon the hydrogen peroxide molecule. On the other hand, if allowed sufficient time relatively small quantities are highly efficient. Heinemann (*J. A. M. A.*, 1913, lx, p. 1603) reaches the conclusion from his experiments that three teaspoonfuls of the official solution after six hours' exposure will destroy 99 per cent. of the bacteria present in a liter of drinking water; this quantity makes about a one to one thousand solution of hydrogen peroxide.

The addition of hydrogen dioxide solution has at times been recommended as an emergency method for the preservation of milk. It effects a partial or complete sterilization of the milk and quickly disappears, being dissociated into H_2O and O. A paper dealing with the length of time during which the H_2O_2 persists in the milk has been published in the *Analyst*, 1915, p. 482, by M. E. Hines.

The solution of hydrogen dioxide is used in medicine as a means of cleansing infected *wounds*, freely suppurating *ulcers*, and the like. Its value in these conditions is probably more in destroying the organic matter which forms a breeding place for the micro-organisms than for its antibacterial action. Its styptic effect—probably due to the activation of the fibrin ferment of the blood and consequent more rapid coagulation—as well as its harmless nature make it a very popular antiseptic for household use. It is sometimes injected into deep cavities for the purpose of determining the presence of pus, which will be signalized by effervescence; the method, however, must be used with caution, as if there be not a free vent for the gas sufficient pressure may be generated within the cavity to cause serious results. Because of its lack of toxicity it is a favorite disinfectant for application to various mucous membranes, especially those of the nose and throat. In *diphtheria* or *tonsillitis* the official solution may be applied pure, either by means of an atomizer or cotton applicator. Diluted with equal parts of water it is often employed as a gargle in *pharyngitis*, or as a mouth wash in *stomatitis*, but it appears frequently to exercise an injurious effect upon the epithelium of the buccal mucous membrane. In slow *hemorrhages* it often exercises a styptic effect, perhaps through activating the specific ferments of the blood which lead to clot formation. Internally the solution of hydrogen dioxide has been used with success by Goodman (*Penna. M. J.*, 1910) and others, in the treatment of *hyperchlorhydria*. It is asserted that it diminishes the acidity of the gastric juice, increases the secretion of mucus and exercises an antiseptic action in the stomach.

One great disadvantage of the solution of hydrogen dioxide is the rapidity with which it deteriorates. The New Hampshire State Board of Health reported in 1912 that more than half of the samples examined were below the Pharmacopœial standard.

Solution of hydrogen dioxide is used in 10 or 15 per cent. aqueous solutions, for various commercial purposes, such as cleaning and bleaching old and stained engravings or oil paintings, or as an auricome for bleaching dark colored hair. It is employed, moreover, in increasing degree in the textile industries for bleaching. Lunge has proposed its use in the ready valuation of chlorinated lime or bleaching powder, which is decomposed by it with the simultaneous liberation of oxygen from both substances in equal amount.

Under the name of *perhydrol* a solution asserted to represent 100 volume per cent. (30 per cent. by weight) of hydrogen dioxide is upon the market.

Dose, one fluidrachm (3.75 mils).

LIQUOR HYPOPHYSIS. U. S.

SOLUTION OF HYPOPHYSIS Liq. Hypophysis [Solution of the Pituitary Body]

(lĭ'quŏr hȳ-pŏph'ȳ-sĭs)

"A solution containing the water-soluble principle or principles from the fresh posterior lobe of the pituitary body of cattle. Extract the finely minced material with slightly acidulated water, boil the solution for ten minutes and filter it. Sterilize this filtrate and preserve it in a sterile condition in glass containers. A transparent liquid, colorless or nearly so, having a faint, characteristic odor. One mil of Solution of Hypophysis, diluted 20,000 times, has the same activity on the isolated uterus of the virgin guinea-pig as a 1 to 20,000,000 solution of beta-iminazolyl-ethylamine hydrochloride when tested as directed by the United States Hygienic Laboratory." *U. S.*

Uses.—The solution of the posterior lobe of the pituitary body possesses the physiological action and therapeutic properties of this organ (see *Hypophysis Sicca*), but has the great advantage of being in a convenient form for administration, especially for hypodermic use. While it is probable that even when given by the mouth the pituitary exerts an effect upon the functions of the body, it is certainly more active when administered hypodermically and is today rarely exhibited orally. As it is impracticable for the retail pharmacist to prepare sterile solutions of the hypophysis of definite activity, the apothecary will ordinarily stock one of the commercial solutions. These preparations—which are sold under various trade names as *pituitrin, hypophysin, pituitary extract,* etc.—vary, however, greatly in their activity and rarely conform to the Pharmacopœial definition. According to Pittenger (*J. A. Ph. A.*, 1917, vi), the commercial solutions of hypophysis are from two to five times as strong as the standard given in the U. S. P.; a fact which it is important that both the physician and the druggist realize, as overdoses of this remedy are capable of much harm. The most frequent use of this drug is as a uterine stimulant, especially in *labor,* although it is sometimes used as a circulatory stimulant in surgical *shock.*

Dose, of the U. S. P. preparation, ten to thirty minims (0.6–1.8 mils).

LIQUOR IODI COMPOSITUS. U. S.

COMPOUND SOLUTION OF IODINE Liq. Iodi Co. [Lugol's Solution]

(lĭ'quŏr ī-ō'dī cŏm-pŏs'ĭ-tŭs)

"An aqueous solution containing not less than 4.8 per cent. nor more than 5.2 per cent. of I and not less than 9.8 per cent. nor more than 10.2 per cent. of KI. Preserve the solution in glass-stoppered bottles, protected from light." *U. S.*

Liquor Iodinii Compositus, *U. S.* 1870; Soluté ioduré de Lugol, *Fr.*; Lugolsche Jodlösung, *G.*

* "Iodine, *five grammes* [or 77 grains]; Potassium Iodide, *ten grammes* [or 154 grains]; Distilled Water, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the iodine and potassium iodide in a sufficient quantity of distilled water to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

In this solution iodine is dissolved in water with the assistance of potassium iodide. Iodine dissolves sparingly in water, but freely in a solution of this salt. In using potassium iodide to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine, and this is the proportion adopted in the U. S. formula. The preparation is a *concentrated* solution of iodine with potassium iodide, and is intended to facilitate the administration of the combination in drops. The present formula does not differ in strength from that of 1880. In the Br. Pharmacopœia a solution is directed having much more iodine than the U. S. solution, and weaker in potassium iodide, the former having about fifty grains of iodine and thirty grains of potassium iodide in the fluidounce, while the latter has nearly twenty-six grains of iodine and fifty-two grains of potassium iodide in the fluidounce, the difference in the fluidounce of the two Pharmacopœias being too small to enter into the calculation. Its name was changed in the 1914 revision of the Br. Pharmacopœia to *Tinctura Iodi Fortis.* (See under Tinctures.) The British solution is made with alcohol, and closely resembles the *Liniment of Iodine* of the *Br. Ph.*, 1885. "Compound Solution of Iodine is a transparent liquid of a deep brown color, having an odor of iodine. A drop of Compound Solution of Iodine when added to 1 mil of starch T.S., diluted with 10 mils of water, produces a deep blue color.

"**Assay for Potassium Iodide.**—Evaporate in a tared, porcelain dish on a water bath about 5 mils of Compound Solution of Iodine, accurately weighed in a stoppered weighing-bottle, repeatedly moisten the residue with distilled water and re-evaporate until it becomes white. It leaves a residue of not less than 9.8 per cent. nor more than 10.2 per cent. of a salt which responds to the tests for identity and purity under *Potassii Iodidum.*

"**Assay for Iodine.**—Dilute about 10 mils of Compound Solution of Iodine, accurately weighed in a stoppered weighing-bottle, with 25 mils of distilled water and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 4.8 per cent. nor more than 5.2 per cent. of I.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.012692 Gm. of I. Each gramme of Compound Solution of Iodine corresponds to not less than 3.8 mils nor more than 4.1 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

Uses.—Lugol's solution is used internally as a means of obtaining the therapeutic effects of

iodine. It is also an efficient chemical antidote to some of the alkaloidal poisons.

Dose, of the U. S. P. solution, from two to five minims (0.12–0.3 mil), three times a day, given in at least four tablespoonfuls of water or of milk, so as to avoid irritation of the stomach.

Off. Prep.—Liquor Iodi Phenolatus, *N. F.*

LIQUOR MAGNESII BICARBONATIS. Br.

SOLUTION OF MAGNESIUM BICARBONATE [Fluid Magnesia]

(lĭ'quŏr măg-nē'shĭ-ī bī-kär-bŏ-nā'tĭs)

Liquor Magnesii Carbonatis, *Br.* 1898; Eau magnésienne, Magnésie liquide, *Fr.;* Kohlensaure Magnesialösung, Magnesiawasser, *G.*

"Magnesium Sulphate, 40 *grammes;* Sodium Carbonate, 50 *grammes;* Distilled Water, *a sufficient quantity.* Dissolve the two salts separately, each in two hundred *millilitres* of the Distilled Water; heat the solution of Magnesium Sulphate to the boiling point; add to it the solution of Sodium Carbonate; boil until carbon dioxide ceases to be evolved; collect the precipitate on a calico filter; wash it with Distilled Water until the filtrate is free from sulphates. Mix the washed precipitate with four hundred *millilitres* of Distilled Water; place the mixture in a suitable apparatus; force into it pure washed carbon dioxide; let the mixture remain in contact with excess of carbon dioxide, retained under a pressure of about three atmospheres, for twenty-four hours or longer; decant the resulting solution, and again pass carbon dioxide into it. Keep the Solution in securely closed bottles." *Br.*

The title of this solution was changed in the British Pharm., 1914, to "Solution of Magnesium *Bicarbonate.* It was formerly solution of Magnesium *Carbonate;* the word bicarbonate more accurately describes the magnesium salt in the finished preparation.

The object of this process is to obtain a solution of magnesium bicarbonate by means of carbon dioxide, the carbonate being insoluble in pure water. The first step is to prepare a freshly precipitated hydrated magnesium carbonate, which is more readily dissolved than is a carbonate which has been kept for some time. As the magnesium carbonate of the Br. Pharmacopœia consists of three molecules of the neutral carbonate and one of magnesium hydroxide with four molecules of water, it follows that, in its preparation from the two salts used in the process, a portion of carbon dioxide escapes, and the boiling is directed to be continued until the escape of the gas ceases, so that the normal composition may be insured, and a longer heat, which might affect the constitution of the carbonate so as to diminish its solubility, avoided. The precipitate is thoroughly washed, in order to remove every trace of sodium sulphate, which may be indicated by the non-action of the test of barium chloride. The next step is to dissolve the precipitated carbonate in water impregnated with carbon dioxide, and, as the solution even thus favored is slowly effected, the carbonate is directed to remain exposed to the action of carbon dioxide, under pressure, for twenty-four hours, and still the whole of the carbonate is not dissolved, and filtration is necessary. According to the Br. Pharm., the solution "effervesces slightly, or not at all, when the containing vessel is first opened. Yields no characteristic *reactions* for sulphates. *Lead limit* 0.5 part per million. *Arsenic limit* 0.2 part per million. 20 millilitres evaporated to dryness yield a white residue, which after calcination weighs not less than 0.16 and not more than 0.19 gramme. This residue is insoluble in *water,* and when dissolved in a dilute acid yields the *reactions* characteristic of magnesium. This Solution contains the equivalent of about 2 grammes of the official Magnesium Carbonate in 100 millilitres; 1 fluid ounce contains the equivalent of about 10 grains." *Br.*

On exposure to the air, some of the carbon dioxide escapes, and a portion of the salt is deposited. According to Muncy, the preparation as it occurs in commerce is usually much below the standard strength.

This solution is but slightly effervescent, is clear, and should be free from bitterness. Nevertheless, its taste is more disagreeable than is that of the undissolved carbonate or hydroxide, over which it has no advantage. (See *Magma Magnesiæ,* page 670.)

Dose, as an antacid laxative, from one to two fluidounces (30–60 mils).

LIQUOR MAGNESII CITRATIS. U. S.

SOLUTION OF MAGNESIUM CITRATE Liq. Mag. Cit.

(lĭ'quŏr măg-nē'shĭ-ī cĭ-trā'tĭs)

"*One hundred mils* of the Solution contains magnesium citrate corresponding to not less than 1.5 Gm. of magnesium oxide (MgO = 40.32)." *U. S.*

Liquor Magnesii Citrici; Solution of Citrate of Magnesium; Limonade purgative au Citrate de Magnésie, *Fr. Cod.;* Flüssige Citronensaure Magnesia, Magnesiumcitratlösung, Magnesiumlimonade, *G.;* Limonata magnesiaca, *It.;* Limonada purgante de citrato magnesico, *Sp.*

* "Magnesium Carbonate, *fifteen grammes* [or 231 grains]; Citric Acid, *thirty-three grammes* [or 1 ounce av., 72 grains]; Syrup, *sixty mils* [or 2 fluidounces, 14 minims]; Purified Talc, *five grammes* [or 77 grains]; Oil of Lemon, *one-tenth of a mil* [or 1½ minims]; Potassium Bicarbonate, *two and five-tenths grammes* [or 39 grains]; Water, *a sufficient quantity.* Dissolve the citric acid in *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of hot water in a suitable dish, and, having added the magnesium carbonate, previously mixed with *one hundred mils* [or 3 fluidounces, 183 minims] of water, stir until it is dissolved. Then add the syrup, heat the mixed liquids to the boiling point, immediately introduce the oil of lemon, previously triturated with the purified talc, and filter the mixture, while hot, into a strong bottle (previously rinsed with

boiling water) of suitable capacity. Introduce enough boiled water to make the product measure *three hundred and fifty mils* [or 11 fluidounces, 401 minims]. Stopper it with purified cotton until cold, then drop in the potassium bicarbonate, and immediately stopper the bottle securely. Lastly, shake the solution occasionally until the potassium bicarbonate is dissolved. Keep the bottle on its side in a cool place, preferably in a refrigerator. *Note.*—In this process the 2.5 Gm. [or 39 grains] of potassium bicarbonate may be replaced by 2.1 Gm. [or 33 grains] of sodium bicarbonate, preferably in tablet form." *U. S.*

This formula first appeared in the second edition of the U. S. Pharmacopœia of 1850. The original formula was soon found to have defects. Four-fifths of the carbonate was dissolved in the citric acid, and the solution filtered into a bottle containing the syrup of citric acid, and then the reserved fifth, mixed with water, was added to the acid citrate, and the bottle tightly corked. The addition of the reserved carbonate was intended to impregnate the preparation with carbon dioxide by its solution in the excess of citric acid. To effect the solution of this reserved carbonate required at least half an hour. But the chief objection to the formula as originally framed was that the magnesium citrate, when the solution was kept for some days, crystallized out in the form of a white granular precipitate, which rendered the solution unfit for medicinal use. This precipitate was found by Procter to be $Mg_3(C_6H_5O_7)_2 + 14H_2O$. This still occurs to some extent, although more slowly, and probably cannot be avoided except by a very great reduction in the amount of magnesia. The U. S. P. (8th Rev.) process improved the formula by increasing the quantity of citric acid, using 33 Gm. instead of 30 Gm. formerly used. The use of potassium bicarbonate introduces potassium citrate, but in too small a proportion to be of any consequence. It is somewhat more convenient to use calcined magnesia in place of the carbonate, and in one of the best processes that we have seen the fifteen grammes of carbonate in the official formula are replaced by five grammes of light calcined magnesia. We prefer a modification in the manipulation of the official process; if instead of the solution being filtered into the bottles containing the syrup it is filtered into a separate vessel, and then the proper quantity poured very carefully down the inside of the bottle, or with the aid of a funnel having only a lateral opening so that the liquid is delivered against the sides of the bottle, so as not to disturb the heavy layer of syrup, if then the crystals of bicarbonate be dropped in, very little loss of carbon dioxide will ensue if the bottle is at once securely stoppered. When the bottle is dispensed, a vigorous shake at once liberates the carbon dioxide, and the patient is sure to have a highly effervescent liquid. Special bottles for this solution can now be procured which have a "patent stopper" attached; they are very convenient. The crown stopper is also frequently seen as devices for applying these are now upon the market in a comparatively inexpensive form. Solid magnesium citrate is best used in the form of the effervescent magnesium citrate of the U. S. P., 1890. (See *U. S. D.*, 19th edition, p. 726.)

The official preparation (U. S. P. IX) differs from that of former pharmacopœias in providing a means for effecting partial sterilization, such as boiling the mixed liquids, rinsing the bottle with boiling water, using boiled water for diluting the mixed liquids, and stoppering the bottle with purified cotton. These measures are helpful in destroying bacteria, but after all has been done the potassium bicarbonate or sodium bicarbonate added at the last may introduce germs which may develop growths. The oil of lemon should be fresh and without terebinthinate odor. The tincture made from fresh lemon peel would probably prove more satisfactory as a flavor.

Properties.—This official solution is founded on a preparation proposed by Roge Delabarre, and improved by Rabourdin, of Paris. It is an aqueous solution of magnesium citrate, containing an excess of citric acid, impregnated with carbon dioxide and sweetened with syrup. When properly prepared, it is a clear liquid, having an agreeable taste like that of lemonade. "Add 1 mil of glacial acetic acid and 3 mils of an aqueous solution of potassium acetate (1 in 2) to 10 mils of Solution of Magnesium Citrate, shake the mixture vigorously, then gently rub the sides of the test tube with a glass rod for a few minutes and allow to stand for one hour; no white crystalline precipitate, soluble in ammonia water, is produced (*tartaric acid*). Dilute 2 mils of the Solution with 8 mils of distilled water and add 5 drops of hydrochloric acid and 1 mil of barium chloride T.S.; no turbidity is produced within one minute (*sulphate*). Dilute 2 mils of the Solution with 8 mils of distilled water and add 5 mils of ammonium oxalate T.S.; not more than a slight turbidity is produced (*calcium*).

"**Assay.**—Transfer 10 mils of Solution of Magnesium Citrate, accurately measured, to a platinum or porcelain dish, evaporate to dryness, and ignite until most of the carbonaceous matter has burned off. Add to the residue 20 mils of diluted hydrochloric acid, heat on a water bath for fifteen minutes, filter if necessary, and wash the residue thoroughly with hot water. To the combined filtrate and washings, which should measure about 100 mils, add an excess of sodium phosphate T.S. (about 20 mils), then add ammonia water gradually, with constant stirring, until slightly alkaline, allow to stand for ten minutes, add 30 mils of ammonia water, and allow to stand for twelve hours. Collect the precipitate on a filter, wash it with dilute ammonia water (1 volume of ammonia water to 3 volumes of water) until 10 mils of the washings, when acidulated with nitric acid, yield not more than an opalescence on the

addition of a few drops of silver nitrate T. S. Dry, and ignite to constant weight. The weight of the magnesium pyrophosphate so obtained is not less than 0.414 Gm., indicating an equivalent of not less than 1.5 Gm. of magnesium oxide in 100 mils of the Solution." *U. S.*

Overlooking the excess of acid which it contains, the salt present is the tribasic citrate, in which the six atoms of hydrogen from two molecules of citric acid are replaced by three atoms of magnesium. Accordingly, it consists of two molecules of citric acid and three atoms of magnesium. It is advisable in preparing the solution to introduce the magnesia in small portions, for if too hastily added it is liable to cause the formation of the neutral citrate, which cannot afterwards be readily dissolved. Dorvault made a solid magnesium citrate which is perfectly and readily soluble, by melting on a sand bath 100 parts of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it 29 parts of calcined magnesia. A pasty mixture is formed, which soon hardens, and may be pulverized for use. Magnesium citrate, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydroxide, but with eight or ten times its weight of water it forms a permanent solution. Simonin found that an insoluble magnesium citrate may be restored to solubility in boiling water by being thoroughly rubbed up with water so as to form a paste. The necessary trituration will be abridged if a little citric acid be added. For other modifications, suggestions, etc., see Kondratowisch, *N. R.*, 1883, p. 246; Neynaber, *A. J. P.*, 1884, p. 472 (the proposed substitution of acetic acid by the latter is not desirable, because of the impossibility of avoiding an empyreumatic taste); also A. B. Stevens, *Proc. Mich. State Pharm. Assoc.*, 1885; and F. W. Sennewald, *Nat. Drug.*, 1887.

Magnesium metatartrate has been proposed, in the place of the citrate, by Léger, who, however, states that as a purgative it is more powerful than the citrate, resembling the sulphate. On account of its pleasant taste it might, perhaps, be substituted for Epsom salt. (See *Metatartaric Acid*, page 81.)

Uses.—This solution is a cooling cathartic, and operates mildly. It has come into extensive use in the United States, on account of the facility with which it may be taken and its acceptability to the stomach.

Dose, as a purge, the whole quantity directed in the formula, or twelve fluidounces (360 mils); as a laxative, half that quantity.

LIQUOR MORPHINÆ ACETATIS. Br.

SOLUTION OF MORPHINE ACETATE

(lĭ'quŏr mŏr-phĭ'næ ăç-ē-tā'tĭs)

Soluté d'Acétate de Morphine, *Fr.;* Essigsaure Morphinlösung, *G.*

"Morphine Acetate, 1 *gramme;* Diluted Acetic Acid, 2 *millilitres;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Acetic Acid; dissolve the Morphine Acetate in the mixture, and add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Morphine Acetate in 100 millilitres; 110 minims contain 1 grain." *Br.*

Morphine acetate often contains a little uncombined morphine, in consequence of the escape of a portion of the acid during its evaporation, and especially when this is pushed to dryness. It is on this account apt to be unreliable. Hence the addition of the diluted acetic acid, which at the same time neutralizes the alkaloid in excess and enables the solution to be completely effected. The alcohol is added as a preservative. The present solution contains about 1 per cent. of morphine acetate and is, therefore, about equivalent in strength to tincture of opium.

Dose, from fifteen to thirty minims (0.9–1.8 mils).

LIQUOR MORPHINÆ HYDROCHLORIDI. Br.

SOLUTION OF MORPHINE HYDROCHLORIDE

(lĭ'quŏr mŏr-phĭ'næ hȳ-drŏ-ç̇hlō'rĭ-dī)

Solution of Hydrochlorate of Morphine, *Br.* 1885; Liquor Morphinæ Muriatis, *Dub.;* Solution of Muriate of Morphia; Soluté de Hydrochlorate de Morphine, *Fr.;* Salzsaure Morphinlösung, *G.*

"Morphine Hydrochloride, 1 *gramme;* Diluted Hydrochloric Acid, 2 *millilitres;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Hydrochloric Acid; dissolve the Morphine Hydrochloride in the mixture, and add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Morphine Hydrochloride in 100 millilitres; 110 minims contain 1 grain." *Br.*

The use of the alcohol is to prevent spontaneous decomposition, that of the acid probably to assist in the solution of the salt. The solution contains about 1 per cent. of morphine hydrochloride.

Dose, from fifteen to thirty minims (0.9–1.8 mils).

LIQUOR MORPHINÆ TARTRATIS. Br.

SOLUTION OF MORPHINE TARTRATE

(lĭ'quŏr mŏr-phĭ'næ tăr-trā'tĭs)

Soluté de Tartrate de Morphine, *Fr.;* Weinsteinsaure Morphinlösung, *G.*

"Morphine Tartrate, 1 *gramme;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water; Dissolve the Morphine Tartrate in the mixture; add sufficient Distilled Water to produce the required volume. This Solution contains 1

gramme of Morphine Tartrate in 100 millilitres; 110 minims contain 1 grain." *Br.*

This solution was introduced into the Br. Ph., 1898, because of the superior solubility and stability of the morphine tartrate, alcohol being used to preserve the liquid. It is of the same strength as the other solutions of morphine, about 1 per cent. It is not intended for hypodermic use and should not be confounded with the *Injectio Morphinæ Hypodermatica.* Various solutions of morphine sulphate have been in vogue, but have been abandoned by the Pharmacopœias on account of their tendency to undergo decomposition. The U. S., 1870, solution (*Liquor Morphinæ Sulphatis*) contained 1 grain of morphine sulphate to the fluidounce; the Br., 1885, solution 4.375 grains in the same quantity. *Magendie's Solution of Morphine* was of the strength of 16 grains to the fluidounce.

Dose, from fifteen to thirty minims (0.9–1.8 mils).

LIQUOR PANCREATIS. Br.

PANCREATIC SOLUTION

(lĭ'quŏr păn-crē'ă-tĭs)

"Pancreatic Solution contains the digestive principles of the fresh pancreas of the pig. Mix two hundred and fifty *millilitres* of Alcohol (90 per cent.) with two hundred *millilitres* of Glycerin and sufficient Distilled Water to produce one thousand *millilitres.* In this mixture macerate for seven days two hundred and fifty *grammes* of the pancreas, freed from fat and external membrane, and finely divided by trituration with washed sand or powdered pumice stone; filter." *Br.*

Liquor Pancreatius; Soluté de Pancréatine, *Fr.;* Pancreatinlösung, Pankreasessenz, *G.*

This official preparation of the Br. Ph., 1898, has been introduced to supply the demand for a liquid digestive solution made from the pancreas; it closely resembles the preparation recommended by Benger. (*Proc. Roy. Soc.,* xxxii, 145; see also *Pancreatinum.*) "When 3 *millilitres* of the Solution together with 0.2 *gramme* of *sodium bicarbonate* and 20 *millilitres* of *water* are added to 80 *millilitres* of milk and the mixture kept at 45° C. (113° F.) for one hour, on placing 5 millilitres of this liquid with 5 *millilitres* of *ether* and 5 drops of *nitric acid* in a stoppered tube and gently inverting the tube three times, no curdy precipitate appears in the lower layer." *Br.*

The solution digests albuminoids, converts starch into sugar in an alkaline solution, albumin and fibrin into peptones, and peptonizes milk. As it acts normally in alkaline solutions, while the gastric juices are strongly acid, its practical value as an internal medicament is doubtful. Its chief value is for the predigestion of foods.

Dose, from one to two fluidrachms (3.75–7.5 mils).

LIQUOR PICIS CARBONIS. Br.

SOLUTION OF COAL TAR

(lĭ'quŏr pī'cĭs căr-bō'nĭs)

Soluté de Goudron de Houille, *Fr.;* Kohlenteerlösung, *G.*

"Prepared Coal Tar, 200 *grammes;* Quillaia Bark, in No. 20 powder, 100 *grammes;* Alcohol (90 per cent.), 1000 *millilitres.* Exhaust the powdered Quillaia Bark with the Alcohol by the *percolation process.* To the resulting tincture add the Prepared Coal Tar, and digest the mixture at 50° C. (122° F.) for two days, stirring occasionally. Cool and decant, or filter." *Br.*

This solution of the Br. Ph., 1898, is practically identical with *Liquor Carbonis Detergens, Coal Tar Saponin,* and the *Liquor Picis Carbonis* of the N. F. IV (see Part III), and similar well-known preparations which have been largely used by dermatologists. The process for solution of coal tar is modelled after that for *compound tincture of coal tar,* proposed by L. A. Duhring. (*Am. J. M. S.*) It owes its virtues largely to phenol and other derivatives of coal tar. (See *Pix Carbonis Præparata.*)

Solution of coal tar is stimulating, and is prescribed, diluted with from ten to fifty parts of water, as a wash in *eczema, psoriasis, pruritus,* and other skin diseases.

LIQUOR PLUMBI SUBACETATIS. U. S. (Br.)

SOLUTION OF LEAD SUBACETATE Liq. Plumb. Subacet. [Goulard's Extract]

(lĭ'quŏr plŭm'bī sŭb-ăç-ē-tā'tĭs)

"An aqueous solution containing lead subacetate approximately $Pb_2O(CH_3.COO)_2 = 548.25$, corresponding to not less than 18 per cent. of Pb. Preserve the Solution in well-stoppered bottles." *U. S.*

Liquor Plumbi Subacetatis Fortis, *Br.,* Strong Solution of Lead Subacetate; Acetum Plumbi, Acetum Saturni, Plumbum Hydrico-Aceticum Solutum; Acétate (sous-) de Plomb liquide, *Fr. Cod.;* Extrait de Goulard, Vinaigre de Plomb (de Saturne), *Fr.;* Liquor Plumbi Subacetici, *P. G.;* Bleiessig, *G.*

* "Lead Acetate, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Lead Oxide, finely powdered, *one hundred and ten grammes* [or 3 ounces av., 385 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the lead acetate in *seven hundred mils* [or 23 fluidounces, 321 minims] of boiling distilled water and add the solution slowly and in portions to the lead oxide, which has previously been rubbed to a smooth paste with *one hundred mils* [or 3 fluidounces, 183 minims] of distilled water, and place in a porcelain dish of about *one liter* [or 33 fluidounces, 6½ fluidrachms] capacity. Boil this mixture during half an hour with occasional stirring, adding distilled water as required to maintain about the original volume. Finally, when cool, filter the solution, protecting it as much as possible from the air, and add sufficient distilled

water, which has previously been boiled and cooled, to make the finished product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

"Lead Acetate, 250 *grammes;* Lead Oxide, in powder, 175 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve the Lead Acetate in seven hundred and fifty *millilitres* of the Distilled Water, add the Lead Oxide, set aside for forty-eight hours, shaking occasionally; filter, and pass through the filter sufficient Distilled Water to produce the required volume."

The Br. Pharm., 1914, adopted a "cold process" for making this solution and inserts an assay process as a test. This is necessary to secure uniformity and establish a standard.

The U. S. P. IX process does not differ essentially from that formerly official. Crystallized lead acetate consists of one atom of lead, two acetic acid groups, and three molecules of water. The formula is $Pb(C_2H_3O_2)_2 + 3H_2O = 379.20$. Litharge, as usually found in commerce, is an impure lead oxide. When solution of lead acetate is boiled with lead oxide, a large quantity of the oxide is dissolved, and a lead subacetate is formed which remains in solution. The precise composition of the subacetate varies with the proportion of lead acetate and of litharge employed. Thus, starting with three molecules of normal acetate, $Pb_3(C_2H_3O_2)_6$, we may have $Pb_3O(C_2H_3O_2)_4$, and $Pb_3O_2(C_2H_3O_2)_2$ formed successively. The latter of these oxyacetates is known as Goulard's, and a mixture of the two constitutes the basis of the official solution. In executing the process, the litharge should be employed in very fine powder, and, according to Thénard, should be previously calcined in order to decompose the lead carbonate which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate. Nevning states that a solution of lead subacetate more permanent than the official one may be prepared by simply allowing litharge to remain for twenty-four hours in a solution of lead acetate, with occasional agitation. This preparation probably contains much less of the lead oxide than does the official solution. Courtonne recommends dissolving seventy-five parts by weight of crystallized lead acetate in one hundred and sixty-five parts of water, and adding eleven parts of ammonia water, sp. gr. 0.923. This quick method has the disadvantage of containing ammonium acetate in small quantity. (*Chem. Ztg.,* 1894.) Several methods have been proposed for making this by a process which will eliminate the necessity of boiling. For Haussmann's method by agitating the lead salts with hot water and subsequently adding the lead oxide and occasionally agitating until cold, see *A. J. P.,* 1897, 559; *A. J. P.,* 1896, 427; *M. R.,* 1896, 329; *Ph. Rev.,* 1896, 250.

In many pharmaceutical manufacturing laboratories when this preparation is made on the large scale, the cold process is always used as it seems to work very well with large quantities, and the final adjustment is then made to the standard strength after assaying the preparation.

Properties.—The solution of lead subacetate of the U. S. Pharmacopœia is "a clear, colorless liquid, odorless and having a very sweet, astringent taste. It is alkaline to litmus but not to phenolphthalein. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate. Specific gravity: about 1.245 at 25° C. (77° F.). When Solution of Lead Subacetate is added to a solution of acacia, it produces a dense, white precipitate (distinction from *normal lead acetate*). Separate portions of Solution of Lead Subacetate, diluted with 10 volumes of recently boiled distilled water, yield a black precipitate with hydrogen sulphide T.S., a yellow precipitate with potassium iodide T.S., and a white precipitate with diluted sulphuric acid. Solution of Lead Subacetate yields with potassium ferrocyanide T.S. a precipitate which is not perceptibly blue or red (*iron or copper*).

"**Assay.**—Transfer about 1.5 Gm. of Solution of Lead Subacetate, accurately weighed, to a 200 ml measuring flask, dilute with 50 mils of recently boiled distilled water, then add 50 mils of tenth-normal oxalic acid V.S., agitate the mixture thoroughly for five minutes, fill to the mark with distilled water, and filter, rejecting the first 20 mils of the filtrate. Add 5 mils of sulphuric acid to 100 mils of the filtrate (representing one-half of the amount of Solution of Lead Subacetate originally taken), warm to about 70° C. (158° F.), and titrate with tenth-normal potassium permanganate V.S. It shows not less than 18 per cent. of Pb.

"Each mil of tenth-normal oxalic acid V.S. used corresponds to 0.010355 Gm. of Pb. Each gramme of Solution of Lead Subacetate corresponds to not less than 17.4 mils of tenth-normal oxalic acid V.S." *U. S.*

"A clear colorless liquid, with a sweet astringent taste; alkaline to *litmus.* Becomes turbid by exposure to the air. Forms an opaque white jelly with *mucilage of gum acacia.* Yields the *reactions* characteristic of lead and of acetates. Specific gravity 1.275. When 1 gramme is diluted with 20 millilitres of *water* and mixed with excess of *N/1 solution of oxalic acid,* the precipitate collected, washed, transferred to a flask and decomposed with excess of *diluted sulphuric acid,* the mixture thus obtained, heated to 60° C. (140° F.), decolorises not less than 17 millilitres of *N/10 solution of potassium permanganate.*" *Br.*

When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Barker, are flat, rhomboidal prisms, with dihedral summits. It has an alkaline reaction, tingeing the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which

it is decomposed. Carbon dioxide throws down a white precipitate of lead carbonate; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbon dioxide from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric and hydrochloric acids free or combined, with hydrogen sulphide and the sulphydrates, with the soluble iodides and chlorides, and, according to Thénard, with solutions of nearly all neutral salts. Solutions of gum, tannin, most vegetable coloring principles, and many animal substances, particularly albumin, produce with it precipitates consisting of the substance added and lead oxide. It should be kept in well-stoppered bottles. It is distinguished from the solution of lead acetate by being precipitated by gum arabic. For a method (other than the official) of assaying this solution volumetrically, see *P. J.*, 1886, 656.

Crystallized Lead Subacetate.—Jeannel prepares crystallized lead subacetate in accordance with the following formula. Triturate six parts of neutral lead acetate with two parts of pure litharge, and add one part of water. Heat in a porcelain dish, stirring with a glass rod, until fusion and finally ebullition occur. After two or three minutes of boiling, filter through paper in a funnel heated by a sand bath. Allow to cool and crystallize. (*J. P. C.*, 4e sér., xi, 54.)

Uses.—This solution is astringent and sedative but is employed only as an external application. It is widely used, especially mixed with an equal part of tincture of opium—a mixture commonly known as *lead water and laudanum*—in inflammation arising from *sprains, bruises, burns, blisters,* etc., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. Blackburn (*J. A. M. A.*, 1906, xlvi, p. 954) reports erythema following the local application of lead water and laudanum, and we have seen blistering apparently resulting from this popular embrocation. From four fluidrachms to a fluidounce (15–30 mils), added to a pint (480 mils) of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker, as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; and poisoning by its injection for *gonorrhea* has been reported. (*Dublin Journ. Med. Sci.*, 1874.) The solution has the common name of *Goulard's extract,* derived from a surgeon of Montpellier by whom it was introduced into general notice, though previously employed.

Off. Prep.—Liquor Plumbi Subacetatis Dilutus, *U. S., Br.;* Ceratum Plumbi Subacetatis, *N. F.;* Mistura Adstringens, *N. F.;* Glycerinum Plumbi Subacetatis, *Br.;* Unguentum Plumbi Subacetatis, *Br.*

LIQUOR PLUMBI SUBACETATIS DILUTUS. U. S., Br.

DILUTED SOLUTION OF LEAD SUBACETATE Liq. Plumb. Subacet. Dil. [Lead Water]

(lī'quọr plŭm'bī sŭb-ăç-ẹ-tā'tīs dị-lū'tŭs)

Aqua Saturnina; Goulard's Lotion, Goulard's Water, *Br.;* Diluted Solution of Subacetate of Lead; Lotion à l'Acétate de Plomb, *Fr. Cod.;* Eau de Saturne, Eau de Goulard, Eau blanche, *Fr.;* Aqua Plumbi, *P. G.;* Bleiwasser, Kuhlwasser, *G.*

* "Solution of Lead Subacetate, *forty grammes* [or 1 ounce av., 180 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the solution of lead subacetate with enough distilled water, previously boiled and cooled to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. This preparation must be preserved in small, well-filled and tightly-stoppered bottles." *U. S.*

"Strong Solution of Lead Subacetate, 12.5 *millilitres;* Distilled Water, recently boiled and cooled, sufficient to produce 1000.0 *millilitres.* Mix." *Br.*

In the edition of the U. S. Pharmacopœia of 1870 the proportion was increased from two to three fluidrachms to the pint, and this proportion has been practically retained in the preparation now official. The direction to dilute the strong solution with distilled water *previously boiled and cooled* is an improvement, as even the small amount of carbon dioxide dissolved in distilled water usually made the lead water cloudy. Owing to the liability to serious results due to the frequent confounding of the name lime water and lead water, it is safer to dispense lead water in a slightly opalescent condition, while lime water should be perfectly transparent. The Br. preparation, though stronger than the old one of the London College, is still feeble. The minute proportion of alcohol in the former British solution can have little effect, and it was omitted from Br. Pharm., 1914. The preparation should be excluded from the air as much as possible.

LIQUOR POTASSII ARSENITIS. U. S. (Br.)

SOLUTION OF POTASSIUM ARSENITE Liq. Pot. Arsen. [Fowler's Solution Liquor arsenicalis Fowleri P. I.]

(lī'quọr pọ-tăs'sī-ī är-sẹ-nī'tīs)

"An aqueous solution containing potassium arsenite, corresponding in amount to not less than 0.975 per cent. nor more than 1.025 per cent. of As_2O_3 (197.92). Preserve the Solution in amber-colored bottles." *U. S.*

Liquor Arsenicalis, *Br.;* Arsenical Solution; Solutio Arsenicalis Fowleri, Kali Arsenicosum Solutum; Soluté d'Arsenite de Potasse, *Fr. Cod.;* Liqueur de Fowler, Liqueur arsénicale de Fowler, *Fr.;* Liquor Kalii arsenicosi, *P. G.;* Fowlersche Tropfen, Fowlersche Lösung, *G.;* Soluzione alcalina di arsenito de potassio, Liquore del Fowler, *It.;* Solucion de arsenito potasico, Licor arsenical de Fowler, *Sp.*

* "Arsenic Trioxide, in fine powder, *ten grammes* [or 154 grains]; Potassium Bicarbonate, *twenty grammes* [or 309 grains]; Compound Tincture of Lavender, *thirty grammes* [or 1

ounce av., 26 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Boil the arsenic trioxide and potassium bicarbonate, in a tared flask, with *one hundred grammes* [or 3 ounces av., 231 grains] of distilled water, until solution has been effected. Then add enough distilled water to make the solution weigh *nine hundred and seventy grammes* [or 34 ounces av., 94 grains]; then add the compound tincture of lavender and filter through paper." *U. S.*

"Arsenious Anhydride, in powder, 10 *grammes;* Potassium Carbonate, 10 *grammes;* Compound Tincture of Lavender, 30 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve the Arsenious Anhydride and the Potassium Carbonate in five hundred *millilitres* of Distilled Water by the aid of heat; cool; add the Compound Tincture of Lavender and sufficient Distilled Water to produce the required volume." *Br.*

This preparation originated with Fowler, of Stafford, England, and was intended as a substitute for the celebrated remedy known under the name of "the *tasteless ague drop.*" It now contains potassium arsenite corresponding in amount to 1 per cent. of arsenic trioxide, and the British solution has been made to correspond with this and the International Proctocol (Part I). It is a potassium arsenite dissolved in water, and is formed by the combination of the arsenic trioxide with the potassium of the bicarbonate or carbonate, carbon dioxide being evolved. In the present U. S. process the bicarbonate has been preferred to the carbonate and in order to expedite the process the quantity has been doubled. As the bicarbonate is decomposed to carbonate by boiling water, there is present in the finished solution some potassium carbonate. According to M. H. Buignet, ebullition disengages the carbon dioxide slowly, so that after four hours' boiling the solution still retains about one-sixth of this gas. The name by which the preparation is designated in the U. S. Pharmacopœia is the more correct. The contact of arsenic trioxide with potassium bicarbonate in the presence of a small quantity of boiling water gives rise to effervescence with decomposition of bicarbonate. It has, however, been denied that potassium carbonate is decomposed by arsenic trioxide, which is supposed to be merely held by it in solution, and, in this view of the nature of the preparation, the British name of *Arsenical Solution* would be appropriate. The compound spirit of lavender is added to give it taste and prevent its being mistaken for water. For Oldberg's process, see *Proc. A. Ph. A.,* 1893, 430; see also *A. J. P.,* 1895, 403.

In making this preparation care should be taken that the arsenic trioxide is pure. This object is best secured by using the form which comes in small pieces, instead of the commercial powder, and powdering the lumps in a mortar. Calcium sulphate is a common impurity in the powdered oxide, and if present will remain undissolved, and cause the solution to be weaker than it should be. Another insoluble impurity in the powdered oxide is calcium arsenite, which is sometimes present to the amount of 25 per cent. (Buignet.) Hence, if the arsenic trioxide does not entirely dissolve, the solution must be rejected. If official arsenious acid is used and the resulting preparation assayed and standardized, these difficulties need cause no fear.

Vanderkleed and E'we (*Proc. P. Ph. A.,* 1916, p. 283) point out that there are substances of widely differing composition offered in the market under the name of potassium arsenite. One of these consists of pure $KAsO_2$, while the other is $KAsO_2.H_3AsO_3$.

Properties.—"Solution of Potassium Arsenite is a clear or faintly opalescent liquid with a pink color and a slight odor of lavender. It is alkaline to litmus. Acidulate strongly 10 mils of the Solution with hydrochloric acid and add an equal volume of hydrogen sulphide T.S.; a yellow precipitate is produced which dissolves in ammonium carbonate T.S. Acidulate 4 mils of Solution of Potassium Arsenite with diluted nitric acid, add 1 mil of silver nitrate T.S. and superimpose a layer of ammonia water upon this liquid; no red or reddish-brown color is observed at the line of contact (*arsenate*).

"**Assay.**—Dilute about 20 mils of Solution of Potassium Arsenite, accurately weighed, with 75 mils of distilled water, acidify the mixture very slightly with diluted hydrochloric acid, then dissolve in the solution 2 Gm. of sodium bicarbonate and titrate the resulting liquid with tenth-normal iodine V.S., starch T.S. being used as indicator. It shows not less than 0.975 per cent. nor more than 1.025 per cent. of As_2O_3.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.004948 Gm. of As_2O_3. Each gramme of Solution of Potassium Arsenite corresponds to not less than 1.97 nor more than 2.07 mils of tenth-normal iodine V.S." *U. S.*

"A reddish liquid, alkaline to *litmus,* and having the odor of lavender. 25 millilitres, neutralised with *hydrochloric acid,* discharge the color of 50.4 millilitres of *N/10 solution of iodine,* the presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation. This Solution contains 1 gramme of Arsenious Anhydride in 100 millilitres; 110 minims contain 1 grain." *Br.*

According to R. Fresenius, solutions of alkaline arsenites slowly absorb oxygen from the air, and are in part converted into arsenates. Hence the propriety of keeping this solution in small bottles well filled. Mohr states that the alkaline reaction of the official solution delays the change, and experience has confirmed this statement. The slight precipitate found in this solution after keeping proved to be silicic acid, caused by the action of the alkaline solution on the glass container.

Uses.—This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arseni Trioxidum.* Its liquid form makes it

convenient for exhibition and gradual increase, and it is the preparation generally resorted to when arsenic is given internally. It has been much employed in *intermittent fever, skin diseases,* and the other affections for which arsenic is employed. In *chorea* it is almost a specific, and in *nervous diseases* of debility it is often very useful. In *malarial affections* and *chorea* it should be administered in ascending doses until the puffiness about the eyes or disturbance of the bowels betrays the arsenical impression. For the peculiar effects upon the human organism, see *Arseni Trioxidum.*

Duflos's antidote to the poisonous effects of Fowler's solution, and of the salts of the acids of arsenic generally, is ferric acetate with excess of base, made by dissolving freshly precipitated ferric hydroxide in acetic acid to saturation, adding an equal quantity of the hydroxide to the solution, and diluting the whole with water to the consistence of cream. If the official solution of ferric acetate be used in an emergency, the free acid should first be neutralized with a little ammonia.

Dose, of potassium arsenite solution, three to five minims (0.2–0.3 mil), which may be gradually increased.

LIQUOR POTASSII CITRATIS. U. S.

SOLUTION OF POTASSIUM CITRATE Liq. Pot. Cit. [Neutral Mixture]

(lĭ'quŏr pŏ-tăs'sĭ-ī cĭ-trā'tĭs)

"An aqueous solution containing not less than 8 per cent. of $K_3C_6H_5O_7$ (306.34), with small amounts of citric and carbonic acids." *U. S.*

Mistura Potassii Citratis; Liquor Kalii Citrici; Citrate de Potasse liquide, *Fr.;* Flüssiges Citronensaures Kali, Kaliumcitratlösung, *G.*

* "Potassium Bicarbonate, *eight grammes* [or 123 grains]; Citric Acid, *six grammes* [or 92 grains]; Distilled Water, *a sufficient quantity,* to make *one hundred mils* [or 3 fluidounces, 183 minims]. Dissolve the potassium bicarbonate and the citric acid, each, in *forty mils* [or 1 fluidounce, 169 minims] of distilled water. Filter the solutions separately and wash the filters with enough distilled water to obtain in each case *fifty mils* [or 1 fluidounce, 331 minims]. Mix the two solutions, and, when effervescence has ceased, transfer to a bottle and stopper tightly. This preparation must not be dispensed unless it has been recently prepared." *U. S.*

Solution of potassium citrate has been made identical with the mixture formerly official as *Mistura Potassii Citratis;* nevertheless the mixture made with lemon juice will continue to be preferred by some practitioners; its formula therefore follows:

Mistura Potassii Citratis, U. S., 1880. *Mixture of Citrate of Potassium.* [*Neutral Mixture.*] *Mistura Neutralis; Potion gazeuse (effervescente),* Fr.—"Fresh Lemon Juice, strained, *one hundred parts* [or four fluidounces]; Bicarbonate of Potassium, about *ten parts,* or *a sufficient quantity.* Add the Bicarbonate of Potassium gradually to the Lemon Juice until it is neutralized. This preparation should be freshly made, when wanted for use."

The *official solution* is stronger than the mixture, and is more definite in composition; lemon juice varies in strength, and consequently the amount of potassium citrate in the resulting mixture cannot be uniform. On the other hand, the mixture is much to be preferred on account of its more agreeable taste. An improvement has been made in the present official solution in directing the acid and the alkaline salt to be dissolved separately, and the direction to dispense the preparation in a fresh condition will undoubtedly lead to the keeping of the filtered solutions, by the pharmacist, in separate bottles, and mixing in equal measures or weights when prescribed. The solutions keep well for a considerable length of time, and there is thus greater convenience and a saving of time and labor.

Properties.—The U. S. Pharmacopœia describes the solution as "a clear, colorless liquid, odorless and having a mildly saline taste. It is slightly acid to litmus. It conforms to the reactions and tests for an aqueous solution of the salt as given under *Potassii Citras,* when concentrated to the proper strength.

"**Assay.**—Evaporate to dryness about 15 mils of Solution of Potassium Citrate, accurately weighed, and proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows not less than 8 per cent. of $K_3C_6H_5O_7$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.051057 Gm. of $K_3C_6H_5O_7$. Each gramme of Solution of Potassium Citrate, after evaporation and ignition, corresponds to not less than 1.57 mils of half-normal sulphuric acid V.S." *U. S.*

Uses.—The solution of potassium citrate has long been used under the name of *neutral mixture, saline mixture,* or *effervescing draught.* It formerly was much used as a refrigerant diaphoretic, in cases of *fever* with dry skin, but has been largely superseded by the more potent antipyretics. It has the therapeutic virtues of potassium citrate and the presence of the carbonic acid often makes it more acceptable to the stomach.

Dose, of official solution, four fluidrachms (15 mils).

LIQUOR POTASSII HYDROXIDI. U. S. (Br.)

SOLUTION OF POTASSIUM HYDROXIDE Liq. Pot. Hydrox. [Liquor Potassæ, Pharm. 1890, Solution of Potassa]

(lĭ'quŏr pŏ-tăs'sĭ-ī hȳ-drŏx'ĭ-dī)

"An aqueous solution containing not less than 4.5 per cent. of KOH (56.11). Preserve Solution of Potassium Hydroxide in bottles made of hard glass, and provided with rubber

stoppers or with glass stoppers coated with petrolatum." *U. S.* "Solution of Potash is an aqueous solution containing in 100 millilitres 5 grammes of pure potassium hydroxide, KOH. It should be preserved in a green glass bottle furnished with an air-tight stopper." *Br.*

Liquor Potassæ, *Br.;* Kali Hydricum Solutum, Lixivium Causticum; Solution of Potash; Potasse caustique liquide, Lessive caustique, *Fr.;* Liquor Kali Caustici, *P. G.;* Aetzkalilauge, Kalilauge, *G.*

* "Potassium Hydroxide, *sixty grammes* [or 2 ounces av., 51 grains]; Distilled Water, *nine hundred and forty grammes* [or 33 ounces av., 69 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the potassium hydroxide in the distilled water." *U. S.*

In the U. S. P. IX the only process for making this solution is the simple one of dissolving potassium hydroxide in sufficient distilled water to make a solution of about 5 per cent. strength (potassium hydroxide not less than 85 per cent., see page 899). The former process of decomposing potassium bicarbonate with lime and mixing with water having been dropped. (See *U. S. D.,* 19th ed., p. 733.)

The British Pharmacopœia, 1914, does not give a detailed process, merely specifying that one hundred millilitres shall contain five grammes of potassium hydroxide.

Properties.—Solution of potassium hydroxide is "a clear, colorless, odorless liquid, having, even when diluted, a very acrid and caustic taste. *It should not be tasted unless largely diluted.* It is strongly alkaline and readily absorbs carbon dioxide from the air. Specific gravity: about 1.046 at 25° C. (77° F.). It conforms to the reactions and tests for an aqueous solution of potassium hydroxide as given under *Potassii Hydroxidum,* when concentrated to the proper strength. Introduce about 20 mils of Solution of Potassium Hydroxide into a flask, stopper, weigh accurately and titrate it directly with normal hydrochloric acid V.S., using methyl orange T.S. as indicator. It shows not more than 5.5 per cent. of alkalinity, calculated as KOH (*carbonate*).

"**Assay.**—Transfer about 50 mils of Solution of Potassium Hydroxide, accurately weighed, to a 250 mil measuring flask, add 20 mils of barium chloride T.S. and fill the flask to the mark with distilled water, which has previously been boiled and cooled. Then thoroughly agitate the liquid, filter it through a dry filter, reject the first 20 mils and titrate 100 mils of the filtrate, representing 20 mils of the solution, with normal hydrochloric acid V.S., using phenolphthalein T.S. as indicator. It shows not less than 4.5 per cent. of KOH, when calculated to the amount of Solution originally taken.

"Each mil of normal hydrochloric acid V.S. used corresponds to 0.05611 Gm. of KOH. Each gramme of Solution of Potassium Hydroxide (after treatment with barium chloride T.S.) corresponds to not less than 0.80 mil of normal hydrochloric acid V.S." *U. S.*

"A colorless, strongly alkaline liquid. Yields no characteristic *reactions* for lead, copper, arsenic, iron, aluminium, calcium, magnesium, sodium, or ammonium, and not more than the slightest *reactions* for carbonates, chlorides, or sulphates. Specific gravity 1.045. 20 millilitres require for neutralisation 17.8 millilitres of *N/1 solution of sulphuric acid.* This Solution contains 5 grammes of Potassium Hydroxide, KOH, in 100 millilitres; 110 minims contain 5 grains." *Br.*

It acts rapidly on animal and vegetable substances, and when rubbed between the fingers produces a soapy feeling, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and forms soap with oily and fatty bodies. It is incompatible with acids, acidulous salts, and all metallic and earthy salts held in solution by an acid; also with all ammonia salts, and with calomel and corrosive sublimate. The two official solutions of potassium hydroxide are now nearly identical in strength, the U. S. solution having the sp. gr. 1.046 at 25° C. (77° F.), and the Br. 1.045 at 15.5° C. (60° F.). On account of its strong attraction for carbon dioxide, solution of potassium hydroxide should be carefully preserved from contact with the air.

Uses.—Solution of potassium hydroxide is powerfully antacid, and mildly diuretic, and was formerly much used, but, on account of its irritant properties, has been superseded by the carbonated alkalies.

Dose, ten to thirty minims (0.6–1.8 mils).

LIQUOR POTASSII PERMANGANATIS.
Br.

SOLUTION OF POTASSIUM PERMANGANATE

(lĭ'quŏr pŏ-tăs'sĭ-ī pĕr-măn'gă-nā'tĭs)

Soluté, de Permanganate de Potasse, *Fr.;* Kaliumpermanganatlösung, *G.*

"Potassium Permanganate, 10 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve. This Solution contains 1 gramme of Potassium Permanganate in 100 millilitres; 110 minims contain 1 grain." *Br.*

This is an unstable 1 per cent. solution of potassium permanganate which decomposes upon exposure and deposits manganese oxides.

Dose, of the British Pharmacopœia, from two to four fluidrachms (7.5–15 mils), equivalent to from 1.1 to 2.2 grains of the salt. Very few stomachs will bear more than one grain (0.065 Gm.) of the permanganate.

LIQUOR SODÆ CHLORINATÆ.
U. S., Br.

SOLUTION OF CHLORINATED SODA Liq. Sod. Chlorinat. [Liquor Sodæ Chloratæ, U. S. 1890, Labarraque's Solution]

(lĭ'quŏr sō'dæ ĕhlŏ-rĭ-nā'tæ)

"An aqueous solution of chlorine compounds of sodium, containing not less than 2.5 per cent. of available Cl. Preserve the Solution in well-

stoppered bottles, in a cool place, protected from light." *U. S.*

Liquor Natri Chlorati; Liquor Natri Hypochlorosi; Bleaching Solution; Chlorure de Soude liquide, *Fr. Cod.;* Liqueur de Labarraque, *Fr.;* Chlornatronlösung, Bleichflüssigkeit, *G.;* Solucion de hipoclorito sodico, Licor de Labarraque, *Sp.*

* "Monohydrated Sodium Carbonate, *seventy grammes* [or 2 ounces av., 205 grains]; Chlorinated Lime, *one hundred grammes* [or 3 ounces av., 231 grains]; Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the chlorinated lime with *five hundred mils* [or 16 fluidounces, 435 minims] of water gradually added until a uniform mixture results. Dissolve the monohydrated sodium carbonate in *five hundred mils* [or 16 fluidounces, 435 minims] of hot water, and add this solution to the chlorinated lime mixture contained in a suitable vessel. Stir or shake the mixture thoroughly and if it becomes gelatinous warm the vessel very gently until its contents again liquefy. Then transfer the mixture to a wetted muslin strainer, returning the first portion until the liquid passes through clear, and when no more liquid drains from it, wash the precipitate with enough water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

"Chlorinated Lime, 100 *grammes;* Sodium Carbonate, 150 *grammes;* Distilled Water, 1000 *millilitres.* Dissolve the Sodium Carbonate in two hundred and fifty *millilitres* of the Distilled Water; thoroughly triturate the Chlorinated Lime with the remainder of the Distilled Water; mix the two liquids; shake occasionally during three or four hours; filter. This Solution should be freshly prepared." *Br.*

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards found to possess valuable therapeutic properties. The U. S. process is practically that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of monohydrated sodium carbonate by one of chlorinated lime. Calcium carbonate is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of sodium carbonate, the presence of which renders the solution more permanent. Sodium bicarbonate has been recommended instead of sodium carbonate, on account of the state of crystalline powder in which the calcium carbonate is precipitated, rendering its separation from the supernatant solution very easy, while the precipitate produced by sodium carbonate is a kind of magma from which the liquor is not readily decanted. It is stated also that a little excess of the bicarbonate is useful in various ways. (*Ann. Thér.,* 1866, 107.)

Properties.—The U. S. solution is "a clear, pale greenish liquid, having a faint odor of chlorine and a disagreeable, alkaline taste. The Solution at first colors red litmus paper blue, and then bleaches it. The addition of hydrochloric acid to the Solution causes an evolution of chlorine and carbon dioxide.

"Assay.—Mix in a flask about 7 mils of Solution of Chlorinated Soda, accurately weighed, with 50 mils of distilled water, add 1 Gm. of potassium iodide and 5 mils of acetic acid and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 2.5 per cent. of available Cl.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.003546 Gm. of available Cl. Each gramme of Solution of Chlorinated Soda corresponds to not less than 7 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"A colorless alkaline liquid with a faint odor of chlorine and astringent taste. Decomposed by *hydrochloric acid,* evolving chlorine. Yields not more than slight *reactions* for calcium or carbonates. Specific gravity 1.054. If 5 millilitres are added to a solution of 1 gramme of *potassium iodide* in 100 millilitres of *water* acidified with 5 millilitres of *hydrochloric acid,* a brownish-red solution is obtained, which requires for decolorisation not less than 37.6 millilitres of *N/10 solution of sodium thiosulphate* (presence of not less than 2.5 per cent. by weight of available chlorine)." *Br.*

This test, like that of our own Pharmacopœia, is intended to determine the chlorine strength of the solution. The acetic or hydrochloric acid liberates the chlorine, which then liberates from the potassium iodide an equivalent quantity of iodine, by which the solution is rendered brown, and, the iodine being converted into hydriodic acid by the sodium thiosulphate, the solution again becomes colorless. The quantity of the solution of the latter salt required to bleach the liquid measures the amount of iodine, and this, that of the chlorine which has separated it. The color of turmeric is first rendered brown, and afterwards destroyed. When carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possess the properties of the original liquid. Solution of chlorinated soda, when exposed to the air, absorbs carbon dioxide and slowly evolves chlorine which acts as a disinfectant.

Nature and Composition.—In their chemical nature these solutions are identical. Assuming the chlorinated lime to be essentially calcium hypochlorite with calcium chloride (see page 265), the solutions, after decantation from the precipitated calcium carbonate, will contain *sodium hypochlorite* with *sodium chloride:*

$$Ca(OCl)_2 + CaCl_2 + 2Na_2CO_3 = 2CaCO_3 + 2NaOCl + 2NaCl$$

Besides these there will be present more or less *sodium carbonate,* according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of sodium carbonate, as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula.

Arny and Dawson (*Proc. A. Ph. A.,* 1908, p. 841) criticized the process for making this

solution and recommended the reduction of the U. S. P. standard for chlorinated lime from 30 per cent. of available chlorine to 25 per cent. largely because it is difficult for pharmacists to procure the drug commercially of this strength.

Uses.—The solution of chlorinated soda possesses the germicidal value of its available chlorine. For the disinfection of large masses of organic matter it is inferior to chlorinated lime, not merely because of its greater cost, but also because of its lower content of chlorine. It is, however, an excellent agent for the disinfection of various utensils which are not injured by its bleaching action, such as clinical thermometers and glass or china ware which has been used by patients with contagious disease. It has also been employed to a considerable extent in the treatment of external infected *wounds* or *ulcers*, as well as in various infected conditions of the vagina, bladder, mouth, or throat. For the latter purposes it is usually well to dilute it with from 15 to 30 parts of water. Where it is used in irrigation, as in washing out the bladder by means of double cannula, half an ounce may be employed in one and one-half pints of water. During the European war a solution of chlorinated soda neutralized with boric acid achieved great notoriety as a germicide in *gun-shot wounds* under the name of *Dakin's solution*. The formula as given by Dakin (*B. M. J.*, 1915, ii, p. 318) is as follows: 140 Gm. of dry sodium carbonate (or 400 Gm. of the crystalline) are dissolved in 10 liters of tap water. Add 200 Gm. of chlorinated lime and shake well. Half an hour later siphon off the clear fluid and filter through cotton. Add 40 Gm. of boric acid, which should yield a solution only faintly alkaline. This solution represents, according to Dakin, between 0.5 to 0.6 per cent. of sodium hypochlorite. Later Dr. A. Carrel submitted a formula for what is called *"Carrel-Dakin Solution"* (Daufresne's technic), giving the following detail for its preparation, and advising its use instead of all previously published formulas:

The requisites of a solution of sodium hypochlorite for surgical use, which have been established by the European war, after numerous tests and a long practical experience are: complete absence of caustic alkali and a concentration of sodium hypochlorite of not less than 0.45, nor more than 0.50 per cent. Three chemical substances are indispensable to Dakin's solution and all should conform to the U. S. P. standards for purity: chlorinated lime, anhydrous sodium carbonate and sodium bicarbonate. Among these three products the latter two are of a practically adequate constancy, but this is not the case with the first. Its content in active chlorine (decoloring chlorine) varies within wide limits, and it is absolutely indispensable to titrate it before using it. Weigh out 20 Gm. of an average sample of chlorinated lime, mix it as completely as possible with 1 liter of ordinary water, and leave it in contact for a few hours, agitating it from time to time. Filter. Measure exactly, with a graduated pipette, 10 mils of the clear fluid; add to it 20 mils of a 1 in 10 solution of potassium iodide and 2 mils of acetic or hydrochloric acid. Drop, a drop at a time, into this mixture a tenth-normal volumetric solution of sodium thiosulphate until decoloration is complete. The number of mils of the hypochlorite solution required for complete decoloration, multiplied by 1.775, gives the weight of the active chlorine contained in 100 Gm. of the chlorinated lime. This figure being known, it is applied to the accompanying table, which will give the quantities of chlorinated lime, of sodium carbonate and of sodium bicarbonate which are to be employed to prepare 10 liters of Carrel-Dakin's solution.

Quantities of Ingredients for Ten Liters of Carrel-Dakin's Solution.

Titer of Chlorinated Lime	Chlorinated Lime, Gm.	Anhydrous Sodium Carbonate, Gm.	Sodium Bicarbonate, Gm.
20	230	115	96
21	220	110	92
22	210	105	88
23	200	100	84
24	192	96	80
25	184	92	76
26	177	89	72
27	170	85	70
28	164	82	68
29	159	80	66
30	154	77	64
31	148	74	62
32	144	72	60
33	140	70	59
34	135	68	57
35	132	66	55
36	128	64	53
37	124	62	52

Example: If it required 16.6 mils of the tenth-normal solution of the sodium thiosulphate for complete decoloration, the titer of the chlorinated lime in active chlorine is:

$$16.6 \times 1.775 = 29.7 \text{ per cent.}$$

The quantities to be employed to prepare 10 liters of the solution will be in this case:

Chlorinated lime	154 Gm.
Dry sodium carbonate	77 Gm.
Sodium bicarbonate	62 Gm.

If crystalline sodium carbonate is being used, then instead of the 80 Gm. of dry carbonate it must be replaced by:

Crystalline sodium carbonate .... 220 Gm.

Preparation of Dakin's Solution.—To prepare 10 liters of the solution: 1. Weigh exactly the quantities of chlorinated lime, sodium carbonate and sodium bicarbonate which have been determined in the course of the preceding trial. 2. Place in a 12-liter jar the chlorinated lime and 5 liters of tap water, agitate

vigorously for a few minutes, and leave in contact for from six to twelve hours, over night, for instance. 3. At the same time dissolve, cold, in the five other liters of water the sodium carbonate and the bicarbonate. 4. Pour the solution of the sodium salts all at once into the jar containing the maceration of chlorinated lime, agitate vigorously for a few moments, and leave it quiet to permit the calcium carbonate to settle as it forms. At the end of half an hour, siphon the liquid and filter it through double paper to obtain an entirely limpid product, which must be protected from light. Exposed to the light solutions of hypochlorite undergo very rapid deterioration and are not fit for use twenty-four hours after their preparation. To guard against this danger, the finished product should be stored in large wicker-covered demijohns of black or amber glass.

Titration of Carrel-Dakin's Solution.—It is a wise precaution to verify, from time to time, the titer of the solution. This titration utilizes the same material and the same chemical substances as are used to determine the active chlorine in the chlorinated lime: Measure out 10 mils of the solution, add 20 mils of 1 in 10 solution of potassium iodide, and 2 mils of acetic or hydrochloric acid. Drop, a drop at a time, into this mixture a tenth-normal solution of sodium thiosulphate until decoloration is complete. The number of mils employed multiplied by 0.03725 will give the weight of the sodium hypochlorite contained in 100 mils of the solution. A solution is correct when, under the conditions given above, from 12 to 13 mils of tenth-normal thiosulphate are required to complete the decoloration:

$$13 \times 0.03725 = 0.485 \text{ per cent. of NaOCl}$$

The Test for the Alkalinity of Carrel-Dakin's Solution.—It is easy to differentiate the solution obtained by this procedure from the commercial hypochlorites and from Labarraque's solution: Pour into a glass about 20 mils of the fluid, and drop on the surface a few centigrams of phenolphthalein in powdered form. Carrel-Dakin's solution, correctly prepared, gives absolutely no change in tint, while in the same conditions Javel water and Labarraque's solution give an intense red coloration which indicates in the latter two solutions the presence of free caustic sodium. (See *J. A. M. A.*, 1916, p. 1777. Also *J. A. Ph. A.*, 1917, p. 458, *Am. Dr.*, 1917, p. 25.)

Another chlorine containing body, known as *Dakin's antiseptic,* is *para-toluene-sodium-sulpho-chloramide,* which is described in *J. A. Ph. A.*, 1917, p. 387. (See also *Chlorazene,* Part II.) *Para-toluene-sulpho-dichloramine,* sold under the name *Dichloramine T,* is soluble in oil and its solution has been called *Dakin's oil* (see *J. A. M. A.*, 1917, vol. lxix, pp. 27, 1076; see also *Dichloramine T,* Part II).

Under the name of *antiformin* an alkaline solution of sodium hypochlorite is largely used in the bacteriological laboratory. This solution contains about 7.5 per cent. of sodium hydroxide and 5.2 per cent. of chlorine. Its especial value lies in its property of liquefying various organic matters and of dissolving most varieties of bacteria. It is especially employed for the purpose of recognizing tubercle bacilli in the sputum; it liquefies the sputum, so that centrifugation is possible, and dissolves other bacteria.

LIQUOR SODII ARSENATIS. U. S., Br.

SOLUTION OF SODIUM ARSENATE Liq. Sod. Arsen.

(lĭ'quŏr sō'dī-ī ăr-sẹ-nā'tĭs)

"An aqueous solution containing not less than 0.975 per cent. nor more than 1.025 per cent. of Na_2HAsO_4 (185.97)." *U. S.*

Liquor Sodii Arseniatis, *Br.* 1885; Solution of Arseniate of Sodium; Soluté d'Arseniate de Soude, *Fr.;* Arsensaure Natronlösung, *G.*

* "Exsiccated Sodium Arsenate, previously dried to constant weight at 150° C. (302° F.), *one gramme* [or 15.4 grains]; Distilled Water, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the exsiccated sodium arsenate in sufficient distilled water to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

"Anhydrous Sodium Arsenate, 1 *gramme;* Distilled Water, sufficient to produce 100 *millilitres.* Dissolve. This Solution contains the equivalent of 1 gramme of Anhydrous Sodium Arsenate in 100 millilitres; 110 minims contain the equivalent of 1 grain." *Br.*

This is simply an official form for the administration of sodium arsenate. (See *Sodii Arsenas* and *Sodii Arsenas Exsiccatus.*) "The Solution conforms to the reactions and tests for an aqueous solution of the salt as given under *Sodii Arsenas Exsiccatus,* when concentrated to proper strength.

"**Assay.**—Pour into a tared flask about 30 mils of Solution of Sodium Arsenate, weigh accurately, heat to 80° C. (176° F.) and add 10 mils of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand for fifteen minutes at 80° C. (176° F.), in a glass-stoppered flask, cool and then titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 0.975 per cent. nor more than 1.025 per cent. of Na_2HAsO_4.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each gramme of Solution of Sodium Arsenate corresponds to not less than 1.05 mils nor more than 1.10 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

It now contains 1 per cent. of exsiccated sodium arsenate, where formerly there was present but 0.87 per cent., and the British solution has been made to correspond in strength. The salt is directed to be dried, in order that the solution may be of a uniform strength, as, from the mode in which the sodium arsenate is ordered to be prepared, it is scarcely possible

that it should always contain precisely the same quantity of water of crystallization. It is important in drying it to limit the heat to 150° C. (302° F.), lest a portion of the arsenic should be volatilized.

Dose, from three to five minims (0.2–0.3 mil), to be cautiously increased, if necessary.

LIQUOR SODII CHLORIDI PHYSIOLOGICUS. U. S.

PHYSIOLOGICAL SOLUTION OF SODIUM CHLORIDE
Liq. Sod. Chlor. Physio. [Physiological Salt Solution Normal Salt Solution]

(lī'quŏr sō'dĭ-ī ȼhlō'rĭ-dī phȳs-ĭ-ǫ-lŏ'gĭ-cŭs)

* "Sodium Chloride, *eight and five-tenths grammes* [or 131 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the sodium chloride in sufficient freshly distilled water to measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] and filter. Then sterilize the solution, preferably in an autoclave, under steam pressure, at a temperature of from 115° to 120° C. (239°–248° F.) for fifteen minutes, or by boiling it during at least one hour, and preserve it in a sterile condition. This solution should not be used after it has been made forty-eight hours." *U. S.*

The Pharmacopœia directs that salt solution may be sterilized by boiling for one hour. If this be done a considerable amount of the water may be evaporated and the concentration of the solution materially altered. This should be avoided as far as possible by using a narrow-necked flask, stoppered with cotton and not boiling too vigorously, whether sterilized in the autoclave or by boiling the flask should be stoppered with cotton before sterilization.

Uses.—When pure water is brought in contact with the blood it causes alteration in the red blood corpuscles, allowing the escape of hemoglobin from them into the plasma; this is known as "laking" of the blood. The addition of inorganic salts to the water, in quantities sufficient to make a solution of the same osmotic tension as the blood serum, prevents this action on the corpuscles. When a solution contains just the amount of salt necessary to prevent laking it is said to be isotonic with the blood. Because of its non-toxicity sodium chloride is the salt usually employed for the purpose of preparing an isotonic solution. The amount of salt necessary for this purpose varies in different animals; in the human being it requires an 0.9 per cent. solution of sodium chloride, but an 0.6 per cent. is isotonic with ox blood. This isotonic solution is sometimes spoken of as *normal salt solution,* an unfortunate term, as it is likely to be confused with the normal solution of sodium chloride used by chemists, which is nearly seven times stronger. A much better term is the official name, *physiological salt solution.* In 1882 Ringer showed that after all the blood had been washed out of the heart with an isotonic sodium chloride solution, the addition of small amounts of calcium and potassium would cause that organ again to begin to contract, and that it would continue beating for some time if supplied with these salts. He therefore suggested that calcium and potassium be added to the sodium chloride solution in preparing a physiologically indifferent fluid. Although Ringer originally recommended the addition of calcium phosphate to saturation for the purpose of supplying the needed lime, as at present used in physiological laboratories *Ringer's solution* has the following composition: sodium chloride, 0.7 per cent.; potassium chloride, 0.03 per cent.; calcium chloride, 0.025 per cent. Subsequently it was shown that if this solution was rendered slightly alkaline it offered a still more favorable medium for the heart. In 1895 Locke suggested the addition of dextrose in order to furnish a food stuff to the heart. *Locke's solution,* which is widely used in physiological laboratories, contains: sodium chloride, 0.9 Gm.; calcium chloride, 0.024 Gm.; potassium chloride, 0.042 Gm.; sodium bicarbonate, 0.02 Gm.; dextrose, 0.1 Gm.; water, 100 mils. A still more recent modification known as *Tyrode's solution* has the following combination: sodium chloride, 0.8 per cent.; potassium chloride, 0.02; calcium chloride, 0.02; magnesium chloride, 0.01; sodium phosphate, 0.005; sodium bicarbonate, 0.1 per cent. Although theoretically these solutions are preferable to that of simple sodium chloride, because more nearly approximating the composition of the bodily fluids, yet practically the reserve supply of calcium and potassium in the human body is so large that it is extremely doubtful whether they are ordinarily superior for medical purposes.

Physiological salt solution is used for the purpose of introducing large quantities of water into the system more rapidly than could be done through the alimentary tract. In cases of low blood pressure due either to severe *hemorrhage*—in which the volume of blood is so greatly reduced as to be unable to properly fill the blood vessels—or due to vasomotor paresis, such as *surgical shock*—when the vessels are so dilated that the normal quantity of blood is unable to fill them—the introduction of large amounts of blood into the circulation, as by intravenous injection of physiological salt solution, by filling the vascular system restores a normal resistance and thereby tends to bring the blood pressure back to the normal. In a similar way when large amounts of fluid have been lost from the body—as in the violent purgation of *Asiatic cholera* or *arsenic poisoning*—the administration of a salt solution by increasing the volume of blood is often of much benefit. As is well known, the volume of the urine and of the sweat depends in large measure upon the volume of the blood and the introduction of large quantities of fluid, as by the injection of physiological salt solution, tends to increase these secretions. It is probable that the increased output of water under these circumstances will

carry with it certain toxic substances, and the method of treatment is widely used in certain cases of systemic poisoning, such as *uremia,* with the idea of increasing the elimination of the toxic material. It is more likely, however, that the benefit from the injection of fluids in cases of extraneous poisonings, such as *corrosive sublimate* or *lead poisoning,* is due more to the dilution of the blood than to the actual increase in elimination.

Physiological salt solution may be administered either intravenously, subcutaneously (*hypodermoclysis*), or through the colon (*enteroclysis*). Absorption through the last channel is relatively slow and enteroclysis is employed chiefly in those conditions where it is desirable to avoid the administration of water by the mouth. In either hypodermic or intravenous injection it is essential that the salt solution be absolutely sterile. For this reason it is necessary not only to make the solution with freshly distilled water, but that it should be resterilized after the addition of the sodium chloride. It is, of course, equally essential that the vessels used for the injection, and also the skin of the patient, should also be properly sterilized. From one pint to two quarts (500–1900 mils) of the physiological salt solution may be injected at one dose and repeated again if necessary in a few hours.

LIQUOR SODII GLYCEROPHOSPHATIS. U. S.

SOLUTION OF SODIUM GLYCEROPHOSPHATE Liq. Sod. Glycerophos. [Solution of Sodium Glycerinophosphate]

(lĭ'quŏr sō'dĭ-ī glĭ-cĕr-ō-phŏs-phā'tīs)

"An aqueous solution of sodium glycerophosphate containing not less than 50 per cent. of the anhydrous salt ($Na_2C_3H_7PO_6$ or $Na_2C_3H_5(OH)_2PO_4 = 216.10$)." *U. S.*

"A clear, colorless or yellowish, syrupy liquid. In other respects it conforms to the reactions and tests for purity under *Sodii Glycerophosphas.*

"**Assay.**—Proceed as directed under *Sodii Glycerophosphas.* It shows not less than 50 per cent. of $Na_2C_3H_7PO_6$.

"Each mil of half-normal hydrochloric acid V.S. used corresponds to 0.10805 Gm. of $Na_2C_3H_7PO_6$.

"Each gramme of Solution of Sodium Glycerophosphate corresponds to not less than 4.63 mils of half-normal hydrochloric acid V.S." *U. S.*

This solution was introduced into the U. S. P. IX for the first time; it contains about 50 per cent. of sodium glycerophosphate and is the product which was sold commercially for many years as sodium glycerophosphate. (See *Sodii Glycerophosphas*).

Dose, five to ten minims (0.3–0.6 mil).

Off. Prep.—Elixir Calcii et Sodii Glycerophosphatum, *N. F.;* Elixir Glycerophosphatum Compositum, *N. F.*

LIQUOR SODII HYDROXIDI. U. S.

SOLUTION OF SODIUM HYDROXIDE Liq. Sod. Hydrox. [Liquor Sodæ, U. S 1890, Solution of Soda]

(lĭ'quŏr sō'dĭ-ī hȳ-drŏx'ĭ-dī)

"An aqueous solution containing not less than 4.5 per cent. of NaOH (40.01). Preserve Solution of Sodium Hydroxide in bottles made of hard glass and provided with rubber stoppers or with glass stoppers coated with petrolatum." *U. S.*

Solution of Caustic Soda; Natrium Hydricum Solutum; Soude caustique liquide, *Fr. Cod.;* Lessive des Savonniers, *Fr.;* Liquor Natri Caustici, *P. G.;* Aetznatronlauge, Natronlauge, *G.;* Solucion de sosa caustica, *Sp.*

* "Sodium Hydroxide, *fifty-six grammes* [or 1 ounce av., 427 grains]; Distilled Water, *nine hundred and forty-four grammes* [or 33 ounces av., 131 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the sodium hydroxide in the distilled water." *U. S.*

Solution of sodium hydroxide is prepared in the same way as solution of potassium hydroxide. In the U. S. P. VIII and IX the process is that of simple solution of sodium hydroxide in water; in the U. S. P., 1890, process by a double decomposition between sodium carbonate and calcium hydroxide, there are formed sodium hydroxide in solution, and calcium carbonate which precipitates:

$$Na_2CO_3 + Ca(OH)_2 = 2NaOH + CaCO_3$$

In this process an excess of lime is used, which is necessary to insure a full decomposition of the carbonate.

Properties.—Solution of sodium hydroxide, sometimes called solution of caustic soda, is "a clear, colorless, odorless liquid, having, when diluted, a very acrid and caustic taste. *It should not be tasted unless largely diluted.* It is strongly alkaline and readily absorbs carbon dioxide from the air. Specific gravity: about 1.056 at 25° C. (77° F.). It conforms to the reactions and tests for an aqueous solution of sodium hydroxide as given under *Sodii Hydroxidum,* when concentrated to the proper strength. Introduce about 20 mils of Solution of Sodium Hydroxide into a flask, stopper, weigh accurately and titrate it directly with normal hydrochloric acid V.S., using methyl orange T.S. as indicator. It shows not more than 5.5 per cent. of alkalinity, calculated as NaOH (*carbonate*).

"**Assay.**—Transfer about 50 mils of Solution of Sodium Hydroxide, accurately weighed, to a 250 mil measuring-flask, add 20 mils of barium chloride T.S. and fill the flask to the mark with distilled water, which has been previously boiled and cooled. Then thoroughly agitate the liquid, filter it through a dry filter, reject the first 20 mils, and titrate 100 mils of the clear filtrate with normal hydrochloric acid V.S., using phenolphthalein T.S. as indicator. It shows not less than 4.5 per cent. of NaOH when calculated to the amount of solution originally taken.

"Each mil of normal hydrochloric acid V.S. used corresponds to 0.04001 Gm. of NaOH. Each gramme of Solution of Sodium Hydrox-

ide corresponds to not less than 1.12 mils of normal hydrochloric acid V.S." *U. S.*

Its properties and tests are the same as those of solution of potassium hydroxide, with the exception that no precipitate is produced by platinic chloride or tartaric acid. The alkali dissolved must be viewed as sodium hydroxide (Na.OH), of which two molecules are formed by the union of the oxide with water, according to the reaction:

$$Na_2O + H_2O = 2Na.OH$$

Uses.—The solution of sodium hydroxide is mildly caustic and actively antacid. For most of the local uses for which caustic soda is employed it is generally too feeble, while for internal administration it is too irritant to the stomach and is rarely employed as a medicine.

Dose, ten to thirty minims (0.6–1.8 mils).

LIQUOR STRYCHNINÆ HYDROCHLORIDI. Br.

SOLUTION OF STRYCHNINE HYDROCHLORIDE [Solution of Hydrochlorate of Strychnine, Brit. Pharm. 1885]

(lĭ'quŏr strĭ̆ĝh-nĭ'næ hȳ-drŏ-ĉhlō'rĭ-dī)

Liquor Strychniæ; Soluté de Chlorhydrate de Strychnine, *Fr.;* Salzsaure Strychninlösung, *G.*

"Strychnine Hydrochloride, 1 *gramme;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water; dissolve the Strychnine Hydrochloride in the mixture, and add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Strychnine Hydrochloride in 100 millilitres; 110 minims contain 1 grain." *Br.*

This is the solution of hydrochloride of strychnine of the British Pharmacopœia which was formerly official as *Liquor Strychniæ;* the name has been made definite, and the strength slightly increased, so as to make it conform with the other active solutions; it contains about 1 per cent. of strychnine. The spirit is added for its preservation. A change was made in the last revision of the Br. Pharm., 1898, whereby strychnine hydrochloride is dissolved directly in water containing a little alcohol. This is said to prevent the tendency of the solution to crystallize in cold weather, a fault of the Br. Ph., 1885, process.

Dose, from three to six minims (0.2–0.4 mil), equal respectively to about one-thirtieth and one-eighteenth of a grain (0.002–0.004 Gm.) of the alkaloid.

LIQUOR ZINCI CHLORIDI. U. S., Br.

SOLUTION OF ZINC CHLORIDE Liq. Zinc. Chlor.

(lĭ'quŏr zĭn'cī ĉhlō'rĭ-dī)

"An aqueous solution containing not less than 48.5 per cent. nor more than 52 per cent. of $ZnCl_2$ (136.29)." *U. S.*

Chlorure de Zinc liquide, Soluté de Burnett, *Fr.;* Flüssiges Chlorzink, Chlorzinklösung, *G.*

* "Zinc, granulated, *two hundred and forty grammes* [or 8 ounces av., 204 grains]; Hydrochloric Acid, *eight hundred and forty grammes* [or 29 ounces av., 276 grains]; Nitric Acid, *twelve grammes* [or 185 grains]; Precipitated Zinc Carbonate, *twelve grammes* [or 185 grains]; Distilled Water, *a sufficient quantity,* to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Add the hydrochloric acid gradually to the zinc and *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of distilled water contained in a glass or porcelain vessel, and allow the mixture to stand until the reaction ceases and the acid is saturated. Then pour off the liquid, add the nitric acid and heat the mixture at a temperature not exceeding 115° C. (239° F.), until a portion, when removed and cooled, solidifies. Allow it to cool, and dissolve the solidified mass in sufficient distilled water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Then add the precipitated zinc carbonate, agitate the mixture occasionally during twenty-four hours, and set it aside until it has become clear by subsidence. Separate the clear Solution by decantation or by means of a siphon, and preserve it in tightly stoppered bottles." *U. S.*

"Granulated Zinc, 400 *grammes;* Hydrochloric Acid, 1100 *millilitres;* Distilled Water, *a sufficient quantity.* Mix the Hydrochloric Acid with five hundred *millilitres* of Distilled Water in a porcelain dish; add the Zinc; apply gentle heat until gas is no longer evolved; boil for half an hour, supply the water lost by evaporation; allow the product to cool. Test a few drops of the resulting liquid for iron and lead. If either be present, filter the remainder of the cooled product into a bottle, and add *solution of chlorine* by degrees, with frequent shaking, until the liquid acquires a permanent odor of chlorine; add Zinc Carbonate in small quantities at a time, with renewed shaking until the whole of the iron or lead is precipitated; filter the liquid and evaporate to one thousand millilitres. If no iron or lead be present, filter the remainder of the cooled product, and evaporate it to one thousand millilitres." *Br.*

The zinc chloride is made in the usual way, by dissolving zinc in hydrochloric acid. The nitric acid in the U. S. process is added in order that any iron present shall be converted into ferric chloride, from which it is afterwards precipitated by the zinc carbonate. In the older processes the former object was accomplished by the use of solution of chlorinated lime, the latter by chalk. This is a decided improvement, as the use of the chalk as a precipitant introduced into the preparation some calcium chloride, while the zinc carbonate adds only a little zinc chloride in solution. Hydrogen dioxide has been used instead of nitric acid as an oxidizing agent by Besthorn and others. The preparation is completed by bringing it to a certain weight by the addition of distilled water, and by filtration to separate the pre-

cipitated iron and any excess of the carbonate. On account of the difficulty of freeing zinc from iron contamination, Francis Hemm proposes the simpler process of making this solution from iron-free zinc oxide; he dissolves 300 Gm. of such zinc oxide in 840 Gm. of hydrochloric acid in a porcelain dish, with the aid of heat, cools, filters, and evaporates the filtrate to 1000 Gm. (*Am. Drug.*, 1900, 199.)

Properties.—As procured by the U. S. P. process, solution of zinc chloride is "a clear, colorless, odorless liquid, having a very astringent, metallic taste, and an acid reaction. Specific gravity: about 1.548 at 25° C. (77° F.). It conforms to the identity and purity tests for an aqueous solution of the salt as given under *Zinci Chloridum*, when taken in proportionate amount.

"**Assay.**—Transfer to a tared flask about 0.6 Gm. of Solution of Zinc Chloride, weigh accurately, and proceed as directed under the Assay for chlorides (see Part III, Test No. 5). It shows not less than 48.5 per cent. nor more than 52 per cent. of $ZnCl_2$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.0068145 Gm. of $ZnCl_2$. Each gramme of Solution of Zinc Chloride corresponds to not less than 71.2 mils nor more than 76.3 mils of tenth-normal silver nitrate V.S." *U. S.*

"A colorless liquid; taste astringent and sweetish. Specific gravity 1.530. Yields no characteristic *reactions* for lead, copper, cadmium, arsenic, iron, aluminium, calcium, magnesium, or sulphates." *Br.*

Uses.—The solution of zinc chloride is actively caustic and a powerful germicide, possessed of deodorant properties. In dilute solution it acts as a stimulating astringent with some antiseptic powers. It has been employed, either in full strength or with equal parts of water, for the destruction of *cancerous ulcers*, especially when there is fetid discharge. It has, however, the disadvantages of destroying healthy as well as diseased tissue and that its action is accompanied with a considerable amount of pain. In dilute solution it is used for its astringent and antiseptic influence in *gleet*, *vaginitis* and, occasionally, in other inflammations of the mucous membranes; for these purposes it may be employed in strengths of from 1 to 5 per cent. Formerly the solution of zinc chloride was largely used as a general disinfectant both for surgical and sanitary purposes, but has been largely replaced by other agents. It is also commonly used for the preservation of bodies for dissection. *Burnett's Disinfecting Fluid* was an aqueous solution of zinc chloride very similar to the present official solution; as originally recommended it was made by dissolving one pound of zinc chloride in five gallons of water, but was commercially often prepared by the natural deliquescence of the crystals.

LIQUORES

SOLUTIONS

(lĭ-quō'rēz)

Solutés, *Fr.*; Liquores, *P. G.*; Lösungen, *G.*; Soluzione, *It.*; Solucion, *Sp.*

The U. S. Pharmacopœia includes in this class of preparations all *aqueous* solutions without sugar in which the substance acted on is wholly soluble in water, excluding those in which the dissolved matter is gaseous or very volatile, as in the Aquæ, or Waters. The British Pharmacopœia does not make this distinction and includes several alcoholic solutions of volatile principles among the liquors.

Although several changes were made in the strength of preparations of this class in the U. S. Pharmacopœia of 1880 for the sake of round numbers and to adjust the relative quantity of solid to the solvent, so as to avoid fractions in the percentages, yet it was a question then whether these were advantages sufficient to overbalance the disadvantage of changing the doses of important preparations. Since the important change was made, which makes the powerful solutions contain one per cent. of active ingredient, it would certainly be a serious mistake to alter this proportion in the future. The standard of 1 per cent. for arsenical solutions was adopted by the Conférence Internationale pour l'Unification de la Formule des Médicaments Héroïques in 1902, and has been accepted by all the Pharmacopœias. The 1 per cent., in this connection, refers not to the substance named in the preparation, but to the substance used in making it. Thus in *Liquor Potassii Arsenitis*, the finished preparation does not contain 1 per cent. of potassium arsenite as might be supposed, but contains 1 per cent. of the arsenic trioxide used in making the preparation.

The Br. Pharm., 1898, introduced ten concentrated infusions, with the object of affording an easy method of making, through dilution, ordinary infusions. The titles were very inappropriate, and the British Pharmacopœia, 1914, dismissed *concentrated infusions*.

LITHII BROMIDUM. U. S.

LITHIUM BROMIDE Lith. Brom.

(lĭth'ĭ-ĭ brō'mĭ-dŭm)

"It contains not less than 85 per cent. of LiBr (86.86). Preserve it in air-tight containers." *U. S.*

Lithium Bromatum; Bromure de Lithium, *Fr. Cod.*; Bromlithium, Lithiumbromid, *G.*

This salt was made official in the U. S. P., 1880. Yvon prepares *lithium bromide* by mixing 37 parts of lithium carbonate, 200 parts of distilled water, and 80 parts of bromine, and passing a current of hydrogen sulphide through the mixture until the color of bromine has disappeared. A slight heat is then applied, to drive off excess of hydrogen sulphide and to

agglutinate the sulphur. After filtration the liquor is concentrated and finally crystallized by desiccating it under a bell glass, over sulphuric acid. It may also be obtained by double decomposition. Lithium sulphate is first formed by treating 37 parts of lithium carbonate with 49 parts of monohydrated sulphuric acid diluted with its own volume of water. Then 119 parts of potassium bromide are dissolved in the smallest possible quantity of water. When the two solutions are mixed, an abundant precipitate of potassium sulphate is produced on the addition of a little alcohol. The whole is evaporated to dryness, the operation finished on a water bath, and the residue is treated with alcohol, which removes only lithium bromide and deposits it again on evaporation. The bromide may then be crystallized from water or kept in solution of known strength. (*P. J.*, Sept. 18, 1876.) No process is given in the Pharmacopœia.

Properties.—It is officially described as "a white, granular salt, odorless and having a sharp, slightly bitter taste; very deliquescent. One Gm. of Lithium Bromide dissolves in 0.6 mil of water at 25° C. (77° F.); also in 0.4 mil of boiling water; freely soluble in alcohol and soluble in ether. An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus. At a low red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame. Silver nitrate T.S., added to an aqueous solution of the salt (1 in 10), produces a yellowish-white precipitate insoluble in nitric acid or in a moderate excess of ammonia water. Add a few drops of ferric chloride T.S. and 1 mil of chloroform to 10 mils of an aqueous solution of the salt (1 in 20) and shake the mixture. The chloroform does not acquire a violet tint (*iodide*). Drop 1 mil of diluted sulphuric acid on about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Dissolve about 0.1 Gm. of Lithium Bromide in 5 mils of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid; filter and wash the precipitate with distilled water, then digest it for ten minutes with 5 mils of ammonium carbonate T.S. and filter. On supersaturating the filtrate with nitric acid, not more than a slight turbidity is produced at once (*chloride*). Five mils of an aqueous solution of the salt (1 in 100) acidulated with 3 drops of hydrochloric acid shows no immediate turbidity with 1 mil of barium chloride T.S. (*sulphate*). Add 5 mils of hydrochloric acid and 5 mils of chlorine T.S. to 0.4 Gm. of Lithium Bromide contained in a flat-bottomed flask of 50 mils capacity, evaporate the mixture almost to dryness on a water bath, add 10 mils of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add 3 drops of hydrochloric acid and boil the solution for three minutes; the resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C. (230° F.), weighs not more than 0.002 Gm. (*other alkalies*). The removal of water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Introduce into a tared weighing-bottle about 0.35 Gm. of Lithium Bromide stopper, weigh accurately, and proceed as directed under the Assay for bromides (see Part III, Test No. 5). It shows not less than 85 per cent. of LiBr.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.008686 Gm. of LiBr. Each gramme of Lithium Bromide corresponds to not less than 97.9 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—Lithium bromide was first brought into notice as a remedy by S. Weir Mitchell, who asserts that its action differs from that of the other bromides only in being more hypnotic. Although careful physiological studies of it are wanting, there is little reason for believing that it differs essentially from other bromides in its influence upon the human organism. It should be administered in dilute aqueous solution. Each drachm of it contains fifty-five grains of bromine, and it therefore exceeds potassium bromine in bromine strength.

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Elixir Lithii Bromidi, *N. F.*; Syrupus Bromidorum, *N. F.*

LITHII CARBONAS. U. S., Br.

LITHIUM CARBONATE Lith. Carb.

(lĭth'ĭ-ī căr'bŏ-năs)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 98.5 per cent. of Li_2CO_3 (73.88). Preserve it in well-closed containers." *U. S.* "Lithium Carbonate may be obtained from native silicates of lithium. It contains not less than 98.5 per cent. of pure lithium carbonate, Li_2CO_3." *Br.*

Carbonas Lithicus; Carbonate of Lithia; Carbonate de Lithine, *Fr. Cod.*; Carbonate lithique, *Fr.*; Lithium Carbonicum, *P. G.*; Lithiumcarbonat, Kohlensaures Lithium, *G.*; Carbonato di litio, *It.*; Carbonato de litina o litico, *Sp.*

The alkali *lithia*, so far as has yet been ascertained, is rare in nature, for, though extensively diffused, exists in very small proportion, except in a few scarce minerals. It was discovered by Arfvedson in 1817, in certain minerals from the iron mines of Utö, as *petalite, triphane,* and a variety of *tourmaline.* (Berzelius.) It has since been found in other minerals, as *lepidolite, spodumene, amblygonite,* etc., and in numerous mineral waters, as those of Carlsbad, Salsomaggiore, Pyrmont, Kissingen, Kreuzmach, Aix-la-Chapelle, Vichy, etc., in Europe, and the Gettysburg spring in the United States, in which it exists generally as a carbonate or a bicarbonate. By spectrum analysis it has been detected in the waters of the Atlantic Ocean and of the

Thames, the Delaware, the Potomac and many other rivers; in the ashes of plants grown on a granite soil, and even in milk and human blood. In the mother waters of tartaric acid, in the factories, it has been found in a proportion to justify extraction. It was at one time largely obtained from a *phosphatic triphyline* found in Bavaria, in which it existed as a phosphate, but this source is said to have been exhausted. There are several methods of extracting lithia from the minerals containing it, an account of which may be seen in *Roscoe and Schorlemmer,* vol. ii, Part I, page 158. They contain the alkali in various proportions, from 4.5 per cent. in lepidolite to 11 per cent. in amblygonite. Lithium carbonate is prepared from lepidolite in the following manner. Ten parts of finely powdered lepidolite, 10 parts of barium carbonate, 5 parts of barium sulphate, and 3 parts of potassium sulphate are fused at a very high temperature in a wind furnace. The heavy barium silicate and sulphate sink to the bottom, and a layer of potassium and lithium sulphates is found at the top of the fused mass. These can be extracted by simple lixiviation, and then the carbonate prepared by double decomposition with ammonium carbonate.

In another process the lepidolite is digested with hot sulphuric acid which produces the sulphates of aluminum and lithium principally, and these are separated by crystallization or precipitation operations.

Lithia, Li_2O, is the oxide of the metal lithium, and ranks in chemical properties with the fixed alkalies. In the form of hydroxide, LiOH, it is white and translucent; does not deliquesce in the air, but absorbs carbon dioxide, and becomes opaque; is fusible below ignition, but not volatilizable at a white heat; is soluble in water, but less so than potassium or sodium hydroxides; is sparingly soluble in alcohol, and in solution has an acrid alkaline taste, caustic properties, and a strong alkaline reaction. The salts of lithium are generally freely soluble, with the exception of the neutral carbonate and phosphate, the latter of which is nearly insoluble. *Lithium,* which was first obtained by Bunsen and Matthiessen, in 1855, is silver-white, brilliant, softer than lead, ductile, capable of welding, and the lightest known solid. Its sp. gr. is 0.594, melting point 180° C. (356° F.), atomic weight 6.94, and symbol Li. For a method of making lithium for scientific demonstration on the small scale by electrolysis, see *Ph. Rev.,* 1899, 264.

Lithium carbonate may be prepared directly from one of the lithia minerals, in the manner already described, or from lithium sulphate or chloride in concentrated solution by adding ammonium carbonate. The precipitated salt should be washed with alcohol and dried.

Properties.—It is "a light, white powder, odorless, and having an alkaline taste; permanent in the air. One Gm. of Lithium Carbonate dissolves in 78 mils of water at 25° C. (77° F.); also in 140 mils of boiling water; almost insoluble in alcohol; dissolved by diluted acids with effervescence. At a low red heat the salt fuses; at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. It imparts a crimson color to a non-luminous flame. A saturated aqueous solution of the salt is alkaline to litmus. Lithium Carbonate, when dissolved in 40 parts of diluted acetic acid, leaves not more than 0.15 per cent. of insoluble residue. Mix 1 part of Lithium Carbonate with 20 parts of distilled water and add hydrochloric acid, drop by drop, with agitation until solution takes place. The resulting solution, after boiling and cooling, responds to the following tests when applied to separate portions: The addition of ammonia water to 5 mils of this solution until it has an alkaline reaction produces neither turbidity nor precipitation either before or after boiling (*iron, aluminum*). Dilute another portion of 4 mils of this solution with 6 mils of distilled water; it does not respond to the Test for heavy metals (see Part III, Test No. 3). Add a slight excess of diluted hydrochloric acid to 0.2 Gm. of Lithium Carbonate contained in a flat-bottomed flask of 50 mils capacity, evaporate the mixture almost to dryness on a water bath, add 10 mils of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add 3 drops of hydrochloric acid and boil the solution for three minutes. The resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C. (230° F.), weighs not more than 0.002 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

"**Assay.**—Dissolve about 1.5 Gm. of Lithium Carbonate, previously dried to constant weight at 100° C. (212° F.) and accurately weighed, in 50 mils of normal sulphuric acid V.S. and titrate the solution with normal potassium hydroxide V.S., methyl orange T.S. being used as indicator. It shows, in the dried salt, not less than 98.5 per cent. of Li_2CO_3.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.03694 Gm. of Li_2CO_3. Each gramme of Lithium Carbonate, previously dried, corresponds to not less than 26.7 mils of normal sulphuric acid V.S." *U. S.*

"White powder, or minute crystalline grains. Taste slightly alkaline. Soluble in 80 parts of *water;* insoluble in *alcohol* (90 per cent.). Aqueous solution alkaline to *litmus.* Soluble with effervescence in *hydrochloric acid;* the solution evaporated to dryness leaves a residue which communicates a crimson color to flame, and, redissolved in *water,* yields a precipitate with *solution of sodium phosphate.* 1 gramme, diffused in about 50 millilitres of *water,* requires for neutralisation not less than 26.6 or more than 27.1 millilitres of *N/1 solution of sulphuric acid, solution of methyl orange* being used as indicator. Yields no character-

istic *reactions* for copper, iron, aluminium, zinc, magnesium, or chlorides, and not more than the slightest *reactions* for calcium or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

F. A. Flückiger states that lithium carbonate is less soluble in warm water than in cold water. He recommends as a test of purity that it should require for solution 70 parts or a little more of water at 15° C. (59° F.), and states further that its solution saturated at 90° C. (194° F.) has the sp. gr. 1.009 at 15° C. (59° F.); this latter solution contains 1 part of the salt in 111.3 parts of water. (*A Pharm.*, 1887, p. 509.)

Effervescing Lithium Carbonate may be made as follows: Take of citric acid, 40 parts, sodium bicarbonate, 50 parts, and lithium carbonate, 10 parts. Powder and mix well, then introduce into a wide flat-bottomed dish, and heat to about 100° C. (212° F.), stirring constantly until the powder becomes granular. Separate the granules of uniform size by means of appropriate sieves, and preserve them in well-stoppered bottles. (See *Lithii Citras Effervescens.*)

Uses.—In 1843 Alexander Uré called attention to the fact that uric acid was comparatively freely soluble in solutions of lithium carbonate. This observation was confirmed by Garrod in 1857 who recommended the use of the metal in both acute and chronic forms of gout. This recommendation has been blindly followed by a large proportion of the medical profession for more than fifty years without questioning the validity of the scientific basis and without any close analysis of the clinical results. Garrod's experiment, however, as pointed out by H. C. Wood, Jr. (*J. A. M. A.*, 1916, lxvi, p. 1069), involved conditions which are absolutely inapplicable to human medicine; as a matter of fact it has been shown that the addition of lithium carbonate even in fatally large doses does not affect the solubility of sodium urate in the blood. Moreover there is no convincing clinical evidence of the usefulness of lithia in *gout*.

The clinical results which have been achieved with the "Lithia Waters" have been due to the water in them and not to the lithium. It has been shown by the Bureau of Chemistry of the U. S. Department of Agriculture, none of the natural lithia waters contain more than one-twentieth grain per gallon, while most of them contain only spectroscopic traces.

In sufficient quantities lithium acts upon the system very much like potassium, being depressant to the nerve centers and to the circulation. The non-toxic salts of lithium, like those of potassium, have a diuretic effect, and if given in sufficient dose may aid in the elimination of various substances from the blood, and incidentally the poisons of *gout*, but are probably not superior to the potash salts. Lithium carbonate has the properties of the other earthy carbonates but, being less soluble than the sodium and potassium salts, is perhaps somewhat less prone to irritate the stomach.

Dose, five to fifteen grains (0.32–1.0 Gm.).

Off. Prep.—Elixir Formatum Compositum, *N. F.;* Sal Potassii Bromidi Effervescens Compositus, *N. F.*

LITHII CITRAS. U. S., Br.

LITHIUM CITRATE Lith. Cit.

(lĭth'ĭ-ī cī'trăs)

"It contains not less than 98.5 per cent. of $Li_3C_6H_5O_7 + 4H_2O$ (281.92). Preserve it in air-tight containers." *U. S.* "Lithium Citrate may be obtained by the interaction of citric acid and lithium carbonate. It contains not less than 98.5 per cent. of pure lithium citrate, $Li_3C_6H_5O_7,4H_2O$." *Br.*

Lithiæ Citras, Lithium Citricum; Citrate of Lithium, Citrate of Lithia; Citrate de Lithine, *Fr. Cod.;* Citronensaures Lithium, Lithiumcitrat, *G.*

Neither of the Pharmacopœias gives at present a process for this salt; the U. S. Pharmacopœia process of 1870 was as follows: "Take of Carbonate of Lithium, *one hundred grains;* Citric Acid, in crystals, *two hundred grains;* Distilled Water, *two fluidounces.* Dissolve the Citric Acid in the water gently heated, and to the solution gradually add the Carbonate of Lithium until perfectly dissolved, heating the solution so long as effervescence is produced. Evaporate, by means of a steam- or sand-bath, to a viscid consistence, dry the residue in an oven, at a temperature of about 240° C. (464° F.), then rapidly pulverize it, and preserve the powder in a well-stoppered bottle." *U. S.*, 1870.

Properties.—Lithium citrate is in the form of "a white powder, or in the granular form, odorless, and having a cooling, faintly alkaline taste. It is deliquescent on exposure to moist air and loses its water of crystallization when heated to 150° C. (302° F.). One Gm. of Lithium Citrate dissolves in 1.4 mils of water at 25° C. (77° F.); very slightly soluble in alcohol. An aqueous solution of the salt (1 in 20) is faintly alkaline to litmus but is not reddened by one drop of phenolphthalein T.S. At a red heat the salt chars, emits inflammable vapors having a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame. Boil an aqueous solution of Lithium Citrate (1 in 20) with an equal volume of calcium chloride T.S.; a white precipitate forms. Treat the residue obtained by igniting 0.4 Gm. of the salt at a red heat with a slight excess of diluted hydrochloric acid, filter, wash the residue with distilled water, evaporate the filtrate and washings almost to dryness on a water bath, in a flat-bottomed flask of 50 mils capacity, add 10 mils of amyl alcohol and cautiously heat the

mixture until the lower aqueous layer has evaporated. Then add 3 drops of hydrochloric acid and boil the solution for three minutes. The resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C. (230° F.), weighs not more than 0.004 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows not less than 98.5 per cent. of $Li_3C_6H_5O_7 + 4H_2O$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.04699 Gm. of $Li_3C_6H_5O_7 + 4H_2O$. Each gramme of Lithium Citrate corresponds to not less than 21 mils of half-normal sulphuric acid V.S." *U. S.*

"Small white crystals. Taste saline, cooling. Soluble in 2 parts of *water*. Yields the *reactions* characteristic of citrates. Heated to redness it blackens, evolving inflammable gases; and the residue, neutralised with *hydrochloric acid*, yields with *alcohol* (90 per cent.) a solution which burns with a crimson flame. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water*, filtered, and well washed, yields a clear solution requiring for neutralisation not less than 10.5 millilitres of *N/1 solution of sulphuric acid*. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million. Free from the impurities indicated under 'Lithii Carbonas.'" *Br.*

Uses.—Lithium citrate, like the corresponding salts of sodium and potassium, is oxidized in the system and appears in the urine as a carbonate. It may be used for precisely the same purposes as the other citrates (see page 897), but has no real advantage. It is the compound which is employed in making the widely used so-called "lithia tablets."

Dose, from ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Lithii Citras Effervescens, *Br.;* Elixir Lithii Citratis, *N. F.;* Sal Lithii Citras Effervescens, *N. F.;* Sal Vichyanum Factitium Effervescens cum Lithio, *N. F.*

LITHII CITRAS EFFERVESCENS. Br.

EFFERVESCENT LITHIUM CITRATE

(lĭth'ĭ-ī cī'trăs ĕf-fẹr-vĕs'cẹns)

Sal Lithii Citratis Effervescens, *N. F.;* Effervescent Salt of Lithium Citrate; Limonade séche au Citrate de Lithine, *Fr.;* Brauselithiumcitrat, *G.*

This effervescent salt was dropped from the U. S. P. IX, but was introduced into the N. F. IV. (See Part III.)

"Sodium Bicarbonate, in powder, 580 *grammes;* Tartaric Acid, in powder, 310 *grammes;* Citric Acid, in powder, 210 *grammes;* Lithium Citrate, in powder, 50 *grammes*. Mix the Lithium Citrate with the Citric Acid, then add the Tartaric Acid, and, lastly, the Sodium Bicarbonate, triturating thoroughly. Place the mixture in a dish or pan of suitable form heated to between 90° and 105° C. (194° and 221° F.). When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it, by means of suitable sieves, into granules of uniform and convenient size. Dry the granules at a temperature not exceeding 55° C. (131° F.). The product weighs about one thousand *grammes*." *Br.*

Uses.—This effervescent salt forms an agreeable method of administering lithia; its medicinal properties are those of lithium citrate.

Dose, two drachms (7.7 Gm.), given in solution.

LOBELIA. U. S., Br.

LOBELIA Lobel.

(lọ-bē'lĭ-ą)

"The dried leaves and flowering tops of *Lobelia inflata* Linné (Fam. *Lobeliaceæ*), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." *U. S.* "Lobelia is the dried flowering herb of Lobelia inflata, *Linn.*" *Br.*

Indian or Wild Tobacco, Asthma-weed, Puke-weed, Gagroot, Vomitwort, Bladder Pod, Eyebright; Lobélie enflée, *Fr. Cod.;* Herba Lobeliæ, *P. G.;* Lobelienkraut, *G.;* Lobelia, *It.*

Lobelia inflata, often called *Indian tobacco*, is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, or alternate, petiolate, the upper sessile, ovate, or oblong, about two inches (5 cm.) long, irregularly toothed, pubescent, pale green. The flowers are numerous, small, disposed in leafy terminal racemes, and upon short axillary footstalks. The calyx is five-toothed and much inflated in fruit. The corolla, which is of a delicate blue, has a labiate border, with the upper lip divided into two, the lower into three segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, oblong, reticulated brown seeds.

Lobelia inflata is a very common weed, growing in the roadsides and in neglected fields throughout the Eastern United States and Canada. Its flowers begin to appear towards the end of July, and continue to expand in succession until the occurrence of frost. All parts of it are medicinal, but, according to Eberle, the root and inflated capsules are most powerful. The plant should be collected in August

or September, when the capsules are numerous, and should be carefully dried. It may be kept whole or in powder. As found in commerce, it is often in oblong compressed cakes, prepared by the Shakers or the herb dealers. Lobelia is grown regularly in the testing gardens of the Bureau of Plant Industry of the U. S. Department of Agriculture. It has been suggested that in cultivating *Lobelia inflata* the seeds should be planted in the autumn. (*Ann. Rep. U. S. Dept. Agric.*, 1905, p. 147.)

Properties.—Dried lobelia has a slightly irritating odor, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended in like manner with a flow of saliva and a nauseating effect. "Stems cylindrical, coarsely and irregularly furrowed, yellowish-green, occasionally purplish and with numerous spreading hairs; leaves alternate, sessile or narrowing into a short petiole, usually more or less broken; when entire, laminæ ovate or oblong, from 2 to 9 cm. in length, obtusely toothed or irregularly serrate-denticulate, each tooth with a yellowish-brown, gland-like apex; pale green and with scattered, bristly hairs; flowers blue in long, loose racemes with short pedicels, calyx tube ovoid, with 5 subulate teeth, corolla tubular, from 3 to 4 mm. in length, 5-parted, the upper 2-lobed portion cleft nearly to the base; stamens with anthers united above into a curved tube enclosing the bifid stigmas; capsules ovoid or ellipsoidal, from 5 to 8 mm. in length, light brown, wholly inferior and enclosing numerous brownish, oblong and coarsely reticulate seeds; odor slight, taste strongly acrid. The powder is dark green, odor irritating; fragments of seed-coat composed of more or less polygonal cells with thick, yellowish walls; occasionally, non-glandular hairs elongated-conical, from 0.3 to 0.6 mm. in length; fragments of stem with tracheæ showing annular or spiral thickenings or simple pores associated with narrow wood-fibers, the walls of the latter being rather thin, more or less lignified and porous; fragments of epidermis of leaf with elliptical stomata, 0.025 mm. in length, and usually with 3 or 4 neighboring cells; pollen grains nearly spherical, from 0.015 to 0.03 mm. in diameter. Lobelia yields not more than 8 per cent. of ash." *U. S.*

"Stems angular, channelled, and furnished with narrow wings; often of a purplish tint; bearing one-celled hairs and the scars of alternate leaves. Leaves irregularly toothed and hairy. Capsules inflated, two-celled, containing, when ripe, minute, oblong, reticulated, brown seeds. In transverse section of the stem, laticiferous vessels in the bast. Somewhat irritating odor; taste at first not marked, but subsequently burning and acrid. Ash not more than 12 per cent." *Br.*

The morphology of *Lobelia inflata* is described and illustrated by Holm in *Merck's Rep.*, xvi, p. 341. The German Pharmacopœia directs that Lobelia should be gathered at the end of the flowering period. A number of the foreign Pharmacopœias do not permit the inclusion of the fruit. The drug of commerce ofttimes is collected late in the season after most of the leaves have fallen and the plant has gone to seed. At times the commercial drug consists of the entire herb, and again may consist entirely of the thick and inert stems.

The activity of lobelia is dependent upon the presence of a liquid alkaloid first isolated by Procter in 1838 and by him named *lobeline.* He obtained it by the following process:

The seeds were treated with alcohol acidulated with acetic acid, until deprived of acrimony, and the tincture was evaporated; the resulting extract was triturated with magnesia and water, and, after repeated agitation for several hours, the liquor, holding lobeline in solution, was filtered; this was then shaken repeatedly with ether until no longer acrid, and the ethereal solution, having been decanted, was allowed to evaporate spontaneously. The residue which was reddish-brown and of the consistence of honey, was deprived of coloring matter by dissolving it in water, adding a slight excess of sulphuric acid, boiling with animal charcoal, saturating with magnesia, filtering, agitating with ether until this fluid had deprived the water of acrimony, and finally decanting and allowing the ether to evaporate. Thus obtained, *lobeline* is a yellowish liquid, lighter than water, of a somewhat aromatic odor, and a very persistent, acrid taste. It is soluble in water, but much more copiously in alcohol and ether, and the latter fluid readily removes it from its aqueous solution. It has an alkaline reaction, and forms soluble and crystallizable salts with sulphuric, nitric, and hydrochloric acids, and a very soluble but not crystallizable salt with acetic acid. It forms an insoluble compound with tannic acid, which instantly precipitates it from its solution. By a boiling heat it is entirely decomposed, losing all its acridity, but when combined with acids it may be subjected to ebullition with water without change. (*A. J. P.*, ix, 105, xiii, 1; see also a paper by W. D. Richardson, Jr., *A. J. P.*, 1872, p. 293.) Siebert, from a study of the crystallized hydrochloride and chloroplatinate, derived the formula $C_{15}H_{23}O_2N$ for the free alkaloid.

Pereira found a peculiar acid which he named *lobelic acid;* besides gum, resin, chlorophyl, fixed oil, lignin, salts of lime and potassium, with ferric oxide. Enders separated an acrid substance which he called *lobelacrin* (*Pharmacographia* 2d edition, 400), but Lewis (*P. J.*, 1878, viii) considers lobelacrin as a mixture of lobeline lobelate, with lobelic acid. Lloyd has isolated a crystalline neutral principle (*Ph. Rund.*, 1887, 32) which melts at 225° C. (437° F.), to which he gave the name *inflatin.* It does not appear to have any therapeutic value. Ac-

cording to Procter the seeds contain a much higher percentage of lobeline than the rest of the plant; from the whole plant he obtained a yield of one-fifth of one per cent. The alkaloid appears to be a rather unstable body, being decomposed by boiling temperature as well as by the caustic alkalies.

Vanderkleed and E'we (*Proc. P. P. A.*, 1916, p. 276) propose a method for assaying this drug and its preparations.

Uses.—Lobelia is said to have been used as a medicine by the aborigines of America, but was first brought into general professional notice by Cutler, of Massachusetts. The leaves or capsules, chewed for a short time, occasion giddiness, headache, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. When toxic doses are taken, these symptoms are very severe, and have added to them burning pain in the fauces or œsophagus, progressive failure of voluntary motion, rapid, feeble pulse, fall of temperature, and finally collapse with stupor or coma; in some cases convulsions precede death. Death has often resulted from its empirical use. Its poisonous effects are most likely to occur when, as sometimes happens, it is not rejected by vomiting.

In large quantities lobelia has a paralyzant effect on the peripheral motor nerves like that of curare, but this action plays little rôle in its therapeutic usefulness. As has been shown by Edmunds (*A. J. Phys.*, 1904, xi, p. 80), it acts upon the sympathetic ganglia like nicotine, first stimulating and secondarily depressing. During the primary stage of stimulation there is increased flow of saliva, dilatation of the pupil, constriction of the blood vessels, slowing of the pulse, and other evidences of sympathetic excitation. The slowing of the pulse at first more than counterbalances the vascular constriction, and the blood pressure is usually lowered; later, however, the pulse becomes very rapid and the blood pressure high. The vomiting appears to be due to an action upon the emetic center. In the secondary stage of poisoning the pupil is contracted, salivary secretion checked, respirations slow, and the blood pressure falls. According to Muto and Iwakawa (*A. E. P. P.*, 1910, lxii), lobeline is a primary stimulant to the respiratory center, the failure in respiration which occurs after toxic doses being due to its paralytic effect on the phrenic nerve. According to Dixon and Brodie (*J. P.* 1903, xxix), it causes a relaxation of the bronchial muscles which may, however, be preceded by a short stage of constriction.

As an emetic lobelia should never be employed. Its most important use in medicine is as a nauseating expectorant in *bronchitis*, especially when associated with bronchial spasm. Large doses will sometimes cause complete cessation of the *asthmatic* paroxysms, but it is more commonly employed between the paroxysms for its combined expectorant and antispasmodic influence.

By the eclectics lobelia is used in a host of convulsive and inflammatory disorders, including *epilepsy, tetanus, diphtheria,* and *tonsillitis.*

The tincture affords the most eligible mode of administration; in asthmatic cases it may be given in doses of fifteen minims (0.9 mil) every hour until an effect is produced. The fluidextract and the tincture are official. The process for the vinegar, which was dropped by the U. S. Pharmacopœia of 1890, will be found in the U. S. Dispensatory, 19th edition, p. 749. Nunes (*T. G.*, 1889) asserts that he has used lobeline in a number of cases of *asthma* with most excellent results in doses of from three-fourths of a grain to six grains a day; but it can scarcely be doubted that he had a very impure alkaloid, and that such doses of a pure sample would be highly dangerous.

Dose, antispasmodic, two to eight grains (0.12–0.5 Gm.).

Off. Prep.—Fluidextractum Lobeliæ, *U. S.;* Tinctura Lobeliæ, *U. S.;* Tinctura Lobeliæ Ætherea, *Br.*

LOTIO HYDRARGYRI FLAVA. Br.

YELLOW MERCURIAL LOTION

(lō'tĭ-ō hȳ-drär'gy-rī flā'va)

Lotio Flava, *N. F.;* Aqua Phagedænica Flava; Yellow Wash, Yellow Lotion; Eau phagédénique, *Fr. Cod.;* Eau divine de Fernel, Phagédénique, *Fr.;* Phagedänisches Wasser, Altschadenwasser, *G.*

"Mercuric Chloride, 4.6 *grammes;* Solution of Lime, 1000.0 *millilitres.* Mix." *Br.*

This lotion is about 11 per cent. stronger than that official in the Br. Ph., 1885. This preparation is official in the N. F. IV. (See Part III.)

The reaction between the mercuric chloride and the calcium hydroxide in this preparation results in the precipitation of the yellow mercuric oxide in a very finely divided condition. It is used as a soothing and antiseptic application in *scrofulous* or *syphilitic ulcers;* it has been especially recommended in scrofulous *conjunctivitis.*

LOTIO HYDRARGYRI NIGRA. Br.

BLACK MERCURIAL LOTION

(lō'tĭ-ō hȳ-drär'gy-rī nī'gra)

Lotio Nigra, *N. F.;* Aqua Phagedænica Nigra; Aqua Nigra, Aqua Mercurialis Nigra; Black Wash, Black Lotion; Eau Phagédénique noire, *Fr.;* Schwarzes Wasser, *G.*

"Mercurous Chloride, 6.85 *grammes;* Glycerin, 50.00 *millilitres;* Solution of Lime, sufficient to produce 1000.00 *millilitres.* Triturate the Mercurous Chloride with the Glycerin and gradually add sufficient Solution of Lime to produce the required volume." *Br.*

The addition of glycerin improves this lotion by aiding in the suspension of the insoluble powder. By the reaction between the calomel and calcium is formed the black mercurous oxide. This lotion has medical properties very similar to those of the yellow wash. It has also been recommended by Shoemaker in *ivy poisoning.* This preparation is official in the N. F. IV. (See Part III.)

LOTIONES

LOTIONS

(lō-tĭ-ō'nēṣ)

Washes; Lotions, *Fr.;* Waschungen, *G.*

This class has been introduced into the British Pharmacopœia in order to give official recognition to two preparations, the *black wash* or *lotio nigra,* and the *yellow wash,* or *lotio flava,* which have long been in use, and which will be found above.

LYCOPODIUM. U. S.

LYCOPODIUM Lycopod.

(lĭ-cŏ-pō'dĭ-ŭm)

"The spores of *Lycopodium clavatum* Linné (Fam. *Lycopodiaceæ*), without the presence or admixture of more than 2 per cent. of impurities." *U. S.*

Club Moss, Stag's horn, Semen Lycopodii, Pulvis Lycopodii, Sulphur Vegetabile; Vegetable Sulphur; Lycopede, *Fr. Cod.;* Soufre végétal, *Fr.;* Lycopodium, *P. G.;* Bärlappsamen, Streupulver, Hexenmehl, Blitzpulver, *G.;* Licopodio, *It., Sp.*

Lycopodium clavatum, commonly called *club moss,* has a trailing, branching stem, several feet long, and thickly beset with linear-awl-shaped, flat, ribless, smooth leaves, tipped with a fine bristle, curved upward, and of a light green color. The fructification is in terminal spikes, single or in pairs, with crowded ovate, entire, pointed scales, bearing in the axil a transversely oval sporangia which splits nearly to the base and contains the narrow reticulate spores. The plant is a native of Europe, Asia, and America, being especially common in the dry woods northward.

The spores are collected in Switzerland and Germany. Lycopodium is "a light yellow, very mobile powder, nearly inodorous and tasteless. It is not wetted by water but floats upon it; when boiled with water it sinks; when thrown into a flame it burns with a quick flash. Under the microscope, the spores of Lycopodium are spherical tetrahedrons, from 0.025 to 0.04 mm. in diameter; in section they vary from plano-convex to triangular, the outer wall or exosporium being extended in the form of slight irregular projections, giving the surface of the spore a reticulate appearance, the reticulations being polygonal and formed of straight sides; when viewed so that the rounded surface of the spores is on the under side, the upper surface is characterized by a distinct, triangular marking, being the edges of the three straight surfaces, extending from the center of the spores to near the outer edge. Lycopodium shows very few, if any, pollen grains of species of Pine, the latter being from 0.04 to 0.07 mm. in diameter, and consisting of three parts, in which a central, convex, generative cell separates the two spherical cells or wings which are blackish, due to the inclusion of air. Lycopodium yields not more than 3 per cent. of ash." *U. S.*

Flückiger by thoroughly comminuting the spores of lycopodium with sand, obtained 47 per cent. of a bland oil of bright yellow color and sp. gr. 0.925, which does not congeal even at –15° C. (5° F.). A. Barkowski obtained from the spores of Lycopodium 48.5 per cent. of a neutral non-drying oil, very similar to almond oil. This oil contains 2 per cent. of a fatty acid called *lycopodic acid* ($C_{18}H_{36}O_4$), 80 per cent. of oleic acid, a minute quantity of a vegetable cholesterin similar to that obtained by Hesse from Calabar beans, 8.2 per cent. of glycerin and 3 per cent. of arachidic, palmitic and stearic acids. The lycopodic acid crystallizes in silky needles, it is doubly refracting like quartz, and appears to be isomeric with dioxystearic acid. (*D. C.,* 1891, 155; see also *A. Pharm.,* 1908, 246.) Stenhouse found volatile bases to be present in very small amount. The ash amounts to 4 per cent. It contains alumina and 1 per cent. of phosphoric acid, and is not alkaline. (*Pharmacographia,* 2d ed., 732.) Lycopodium is sometimes admixed with pine pollen which is probably to be looked upon as an accidental contamination. In the same way, it may contain small quantities of talcum and starch. It is sometimes adulterated with a resinous compound made from rosin, ferruginous earths, shellac, sulphur, turmeric, talcum, dextrin or the cereal starches.

In Nashville, Tenn., a specimen came into the possession of Benj. Lillard which was found to contain one-half of its bulk of dextrin. (*Ch. Ph.,* Sept., 1873.) Folleto recommends two reactions to detect pollen: one by adding to a syrupy solution of zinc chloride, potassium iodide and iodine to saturation; the pollen is colored yellow by this reagent, lycopodium is not colored; the other reagent is methyl-green, which colors pollen green, but does not color lycopodium. (*Ph. Centralh.,* 1896, 527.)

Uses.—Lycopodium is used as an absorbent application to *excoriated surfaces,* especially those which occur in the folds of the skin in infants. In pharmacy it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. The moss itself has been esteemed diuretic and antispasmodic; its decoction has been employed in *rheumatism, diseases of the lungs and kidneys,* and in the removal of *plica Polonica,* but it has fallen into complete desuetude. One of the ingenious uses for lycopodium in microscopy is to mix a little of it with an unknown powder or on a slide on which a mount is made. The spores are easily recognizable and

distinguishable from other elements and give an excellent idea of the approximate size of the elements which are being observed, as the spores are almost uniformly 40 microns in size.

MAGMA BISMUTHI. U.S.

BISMUTH MAGMA Magma Bism. [Milk of Bismuth]

(măg'mą bĭz-mū'thī)

"Bismuth Magma yields not less than 5.6 per cent. nor more than 6.2 per cent. of Bi_2O_3.

* "Bismuth Subnitrate, *eighty grammes* [or 2 ounces av., 360 grains]; Nitric Acid, *one hundred and twenty mils* [or 4 fluidounces, 28 minims]; Ammonium Carbonate, *ten grammes* [or 154 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the bismuth subnitrate with *sixty mils* [or 2 fluidounces, 14 minims] of distilled water and *sixty mils* [or 2 fluidounces, 14 minims] of nitric acid in a flask and agitate, warming gently until solution is effected. Pour this solution, with constant stirring, into *five thousand mils* [or 169 fluidounces, 33 minims] of distilled water containing *sixty mils* [or 2 fluidounces, 14 minims] of nitric acid. Dilute *four hundred and eighty mils* [or 16 fluidounces, 111 minims] of ammonia water with *four thousand mils* [or 135 fluidounces, 122 minims] of distilled water in a glazed or glass vessel of at least *twelve thousand mils* [or 405 fluidounces, 367 minims] capacity. Dissolve the ammonium carbonate in this solution and then quickly pour the bismuth solution into it with constant stirring. If the mixture is not distinctly alkaline, add sufficient ammonia water to make it so and allow it to stand until the precipitate has subsided, then pour or siphon off the supernatant liquid and wash the precipitate twice with distilled water, by decantation. Afterwards transfer the magma to a strainer of close texture, arranged in a percolator so as to provide continuous washing with distilled water, the outlet tube being elevated to prevent the surface of the magma from becoming dry, and allow the operation to proceed until the washings cease to react with phenolphthalein T.S. Then drain the moist magma, transfer it to a graduated vessel and add sufficient distilled water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly, transfer to bottles and stopper tightly." *U. S.*

It is officially described as "a thick, white, opaque liquid containing bismuth hydroxide and bismuth subcarbonate in suspension in water. It is neutral to litmus and phenolphthalein. One mil of hydrochloric acid added to 1 mil of Bismuth Magma produces a clear solution. Pour the clear solution into 10 volumes of distilled water; a white precipitate is produced.

"**Assay.**—Evaporate to dryness about 10 Gm. of Bismuth Magma, accurately weighed, and ignite the residue to constant weight; the residue corresponds to not less than 5.6 per cent. nor more than 6.2 per cent. of the weight of Bismuth Magma taken." *U. S.*

This preparation was introduced into the U. S. P. IX with a view of affording a liquid preparation which may be used in some cases to replace the powdered form of bismuth salt.

A modified formula has been suggested by S. Bertha Müller (*A. J. P.*, 1914, ii), in which 50 grammes of bismuth subnitrate are dissolved in 50 grammes of nitric acid which has previously been diluted with an equal volume of water; the solution is then made up to a volume of 300 mils by adding water, and it is then filtered through cotton. Eighty grammes of ammonium carbonate are dissolved in 3000 mils of distilled water containing 3 grammes of sodium chloride. The acid solution of bismuth nitrate is then poured into the alkaline solution with constant stirring, the resulting precipitate is washed thoroughly by decantation, using a 1-1000 sodium chloride solution. Finally it is allowed to settle to 1000 mils.

Uses.—This new preparation of bismuth affords a convenient form for exhibiting this metal, especially to infants. Hulse (*J. A. M. A.*, 1910, lxv, p. 236) finds, however, that this type of preparation does not produce as satisfactory therapeutic results in children as the powdered bismuth subnitrate. It is used in various forms of *diarrhea*, especially in the so-called *summer complaint*.

The *dose* for an adult is one to four fluidrachms (3.9–15.0 mils), equivalent to, approximately, four to sixteen grains (0.25–1.0 Gm.) of bismuth subcarbonate.

MAGMA MAGNESIÆ. U. S.

MAGNESIA MAGMA Magma Mag. [Milk of Magnesia]

(măg'mą măg-nē'shĭ-æ)

"Magnesia Magma yields not less than 6.5 per cent. nor more than 7.5 per cent. of $Mg(OH)_2$ (58.34)." *U. S.*

* "Magnesium Carbonate, in fine powder, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Sodium Hydroxide, *eighty grammes* [or 2 ounces av., 360 grains]; Distilled Water, *a sufficient quantity* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the magnesium carbonate with enough distilled water (about *five hundred mils* [or 16 fluidounces, 435 minims]) and make a smooth mixture. Dissolve the sodium hydroxide in *four hundred mils* [or 13 fluidounces, 252 minims] of distilled water, add the solution to the magnesia mixture with constant stirring, and agitate it frequently during fifteen minutes. Wash the resulting magma by decantation, using *two thousand mils* [or 67 fluidounces, 301 minims] of distilled water each time, until the red color produced in 50 mils of the washings by 3 drops of phenolphthalein T.S. is discharged by the addition of 1 drop of diluted sulphuric acid. Then allow the precipitate to subside until it measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], decant the

supernatant liquid, transfer the product to wide-mouthed bottles, and tightly stopper with corks which have been dipped in melted paraffin. NOTE.—The distilled water in this preparation may be replaced by water which has been heated to boiling with powdered magnesium carbonate (5 Gm. in each 1000 mils) and then filtered. One-half mil of oil of peppermint, or a sufficient quantity of oil of anise or other suitable flavoring may be added if desired." *U. S.*

This preparation was introduced into the U. S. P. IX for the first time. The N. F. III magma was made by the interaction of magnesium sulphate and sodium hydroxide in water.

It is officially described as "a thick, white liquid containing magnesium hydroxide in suspension in water. It is alkaline to litmus and phenolphthalein. The addition of 2 mils of diluted hydrochloric acid to 1 mil of Magnesia Magma causes the evolution of not more than a few isolated bubbles and the resulting solution is not more than slightly turbid. Add 0.5 Gm. of ammonium chloride to the solution, filter, and render the filtrate alkaline with ammonia water; no precipitate is produced, but upon the addition of sodium phosphate T.S. to this alkaline solution, a white precipitate appears. Dilute 10 mils of Magnesia Magma with distilled water to make 100 mils, and allow it to stand until the precipitate has settled. Then remove 50 mils of the clear liquid and evaporate it to dryness on a water bath. The residue, when dried to constant weight, does not exceed 0.005 Gm., and, when dissolved in a few mils of distilled water and a drop of methyl orange T.S. added, yields a red color upon the addition of 5 drops of tenth-normal sulphuric acid V.S.

"**Assay.**—Transfer about 5 Gm. of Magnesia Magma to a tared flask, stopper and weigh accurately, add 25 mils of normal sulphuric acid V.S., and, after solution is complete, titrate the excess of acid with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. It shows an amount of magnesium hydroxide corresponding to not less than 6.5 per cent. nor more than 7.5 per cent. of the weight of Magnesium Magma taken.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.02917 Gm. of $Mg(OH)_2$. Each gramme of Magnesia Magma corresponds to not less than 2.23 mils nor more than 2.57 mils of normal potassium hydroxide V.S." *U. S.*

The official process which is that of McNeary (*J. A. P. A.*, 1916, p. 611) works very well, and is a great improvement over the process of the N. F. III and other processes based upon the double decomposition of soluble magnesium salts and alkaline carbonates in aqueous solutions. Of the double decomposition processes the best is that of Beringer. (*Proc. N. J. P. A.*, 1913, p. 46.) Another formula was suggested by Hensel, *J. A. P. A.*, 1914, p. 1118. A report on the assay of commercial samples was made by LaWall, *J. A. P. A.*, 1914, p. 1002. Another method of making milk of magnesia is to take a freshly calcined magnesium oxide made especially for the purpose, and hydrating it under carefully specified conditions with distilled water. This method has the advantage that no washing whatever is necessary. It does not give uniform results, however, in the hands of different persons.

Magma magnesia, popularly known as *milk of magnesia,* is an excellent and convenient alkali, useful as an antacid and mild laxative in *hyperacidity of the stomach,* whether due to *hypochlorhydria* or *fermentative dyspepsia,* and is useful for the other purposes for which magnesium oxide is used. One drachm is equivalent to approximately four grains of magnesium oxide. Milk of magnesia is also widely employed as a dentifrice, and especially for the correction of acid conditions of the mouth. For this purpose the addition of a trace of some aromatic oil, such as peppermint or anise, is a great advantage.

Dose, one to four fluidrachms (3.75–15 mils).

MAGNESII CARBONAS. U. S. (Br.)

MAGNESIUM CARBONATE Mag. Carb.

(măg-nē'şĭ-ī cär'bo-năs)

"A mixture of hydrated magnesium carbonate and magnesium hydroxide, corresponding to not less than 39.2 per cent. of MgO (40.32) and containing not more than 0.8 per cent. of CaO." *U. S.*

Magnesii Carbonas Levis, Light Magnesium Carbonate, *Br.;* **Magnesii Carbonas Ponderosus,** Heavy Magnesium Carbonate, *Br.;* Magnesia Hydrico-carbonica, Carbonas Magnesicus, Magnesia Alba, Magnesiæ Carbonas, Carbonate of Magnesia; Carbonate de Magnésie officinal, *Fr. Cod.;* Magnésie blanche, *Fr.;* Magnesium carbonicum, *P. G.;* Magnesiumcarbonat, Kohlensaure Magnesia, Weisse Magnesia, *G.;* Idrocarbonato di Magnesio Carbonato, Carbonato di Magnesia, *It.;* Carbonato Magnesico, Magnesia blanca, *Sp.*

In the U. S. P. IX magnesium carbonate is official under one name "Magnesii Carbonas;" this corresponds nearly with "Magnesii Carbonas Levis" of the British Pharmacopœia. A Heavy Magnesium Carbonate is also official in the British Pharmacopœia.

Magnesium carbonate sometimes occurs as a native mineral known as *magnesite,* the best deposits of which are those of the Grecian Archipelago, though a common variety is found in Chester Co., Pa. That which is sold in commerce is prepared on a large scale by the manufacturer. In the British Pharmacopœia directions are given for preparing it in two forms: that of *Magnesii Carbonas Levis,* or Light Magnesium Carbonate; and that of *Magnesii Carbonas Ponderosus,* or Heavy Magnesium Carbonate. The following are the directions:

1. MAGNESII CARBONAS LEVIS. *Light Magnesium Carbonate,* Br.—"Light Magnesium Carbonate is a hydrated magnesium oxycarbonate obtained by the following process:—Magnesium Sulphate, 125 *grammes;* Sodium Carbonate, 150 *grammes;* Distilled Water, *a sufficient quantity.* Dissolve the Magnesium Sul-

phate and the Sodium Carbonate separately, each in one thousand *millilitres* of cold Distilled Water; mix the solutions; boil the mixture for fifteen minutes; transfer the precipitate to a calico filter; wash it with boiling Distilled Water until the washings are free from sulphates, and dry at a temperature not exceeding 100° C. (212° F.)." *Br.*

The resulting carbonate is characterized in the British Pharmacopœia as "a very light, white powder, which, when examined under the microscope, is found to consist of amorphous particles with numerous slender prisms intermixed. It otherwise possesses the general characters and responds to the tests described under 'Magnesii Carbonas Ponderosus.'" *Br.*

2. MAGNESII CARBONAS PONDEROSUS. *Heavy Magnesium Carbonate,* Br.—"Heavy Magnesium Carbonate is a hydrated magnesium oxycarbonate obtained by the following process:—Magnesium Sulphate, 125 *grammes;* Sodium Carbonate, 150 *grammes;* Distilled Water, boiling, *a sufficient quantity.* Dissolve the Magnesium Sulphate and the Sodium Carbonate separately, each in two hundred and fifty *millilitres* of the Distilled Water; mix the solutions, and evaporate to dryness; digest the residue for half an hour with five hundred *millilitres* of the Distilled Water; collect the insoluble matter on a calico filter, wash with the Distilled Water until the washings are free from sulphates, and dry at a temperature not exceeding 100° C. (212° F.)." *Br.*

This is essentially the old process of the Dublin College, and yields a product which is characterized in the British Pharmacopœia as "a white granular powder. Readily soluble with effervescence, in the diluted mineral acids, the solutions yielding the *reactions* characteristic of magnesium. Loses from 56 to 58 per cent. of its weight when heated to redness. Yields no characteristic *reactions* for aluminium, copper, or calcium, and not more than the slightest *reactions* for iron, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million." *Br.*

The following method is said to be pursued by some of the best manufacturers. To a saturated solution of 100 parts of magnesium sulphate, a solution of 125 parts of crystallized sodium carbonate is gradually added, the solutions being constantly stirred. The mixture is heated to ebullition, to complete the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with barium salts. When sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it a square and compact form. According to Otto and Gabler, very pure magnesium carbonate is made at Nauheim, Germany. Pattinson's process is used. It depends upon the fact that, on treating calcined dolomite, in the presence of water, with carbon dioxide under pressure, the magnesia dissolves as bicarbonate before any of the accompanying lime enters in solution. The calcined and finely powdered mineral is introduced, together with water, into a cylinder with a horizontal axis, and, while it is being kept in constant motion by a stirring apparatus, carbon dioxide, under a pressure of five to six atmospheres, is forced into it. The resulting solution of magnesium bicarbonate, which is perfectly free from lime, if the process has been properly managed, is then transferred to a vertical cylinder, where it is heated with steam, whereby magnesium carbonate is separated, which is collected, formed into prismatic pieces, and dried. The carbon dioxide required issues from the earth immediately outside of the factory, and the dolomite is furnished by the quarries of May and Urban, near Dietz and Steelen on the Lahn. (*A. Pharm.*, Aug., 1880; *N. R.*, Sept., 1881.) J. G. Ferrier criticized the processes for making the carbonates by the British Pharmacopœia; he stated that there was a conspicuous want of uniformity in the results obtained. (*P. J.*, 1904, 586.)

The density of magnesium carbonate is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch upon the use of sodium carbonate in its preparation. Much of the magnesium carbonate formerly used in this country was imported from England and Ireland, but that now consumed in the United States is chiefly a home product. The Keasbey & Mattison Company, who are the largest manufacturers of carbonate at the present time, use the process of decomposing calcined dolomite by forcing carbon dioxide into its aqueous mixture, and heating this to precipitate the carbonate. When made from bittern, magnesium carbonate is contaminated with calcium carbonate, salts of lime being contained in sea water, and when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided is to prepare pure magnesium sulphate by repeated crystallization, and to use a pure sodium carbonate. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia. Kippenberger prepares crystallized magnesium carbonate by shaking *freshly* precipitated magnesium carbonate with a solution of potassium bicarbonate at the ordinary temperature; much of the magnesium carbonate dissolves and crystallizes out of the filtered solution upon standing for a day. Sodium bicarbonate may be used instead of the potassium salt, but the crystals are smaller. (*Zeit. Anorg. Chem.*, 1894, 177.)

Properties.—Magnesium carbonate is inodorous, nearly insipid, perfectly white, smooth to the touch, and nearly insoluble in water, requiring 2493 parts of cold and 9000 parts of hot water for solution. It is decomposed by

strong heat, by all the acids, by potassium sodium, calcium, barium and strontium hydroxides, and by acidulous and metallic salts. It is officially described as in "light, white, friable masses, or as a bulky, white powder, without odor, and having a slight, earthy taste; permanent in the air. Magnesium Carbonate is practically insoluble in water, to which, however, it imparts a slightly alkaline reaction; insoluble in alcohol; dissolved by dilute acids with effervescence. When strongly heated, it loses water and carbon dioxide, and is converted into magnesium oxide. A solution of Magnesium Carbonate in diluted hydrochloric acid, when mixed with ammonium chloride T.S. and an excess of ammonia water, yields with sodium phosphate T.S. a white crystalline precipitate. Heat to boiling, 1 Gm. of Magnesium Carbonate with 50 mils of distilled water, and, after cooling, filter and evaporate the filtrate to dryness on a water bath; not more than 0.01 Gm. of residue remains (*soluble salts*). Dissolve 2.5 Gm. of Magnesium Carbonate in 50 mils of diluted hydrochloric acid and 200 mils of distilled water. The solution is colorless, and a 20 mil portion does not give an immediate blue coloration upon the addition of 5 drops of potassium ferrocyanide T. S. (*iron*). Dissolve 0.5 Gm. of Magnesium Carbonate in a slight excess of diluted hydrochloric acid (about 5 mils) and dilute with distilled water to 25 mils. Ten mils of this solution does not respond to the Test for heavy metals (see Part III, Test No. 3). Dissolve 4 Gm. of Magnesium Carbonate in 50 mils of diluted hydrochloric acid, in a beaker of about 800 mils capacity. Dilute this solution to about 400 mils with distilled water, add 5 Gm. of ammonium chloride, heat to boiling, then add 50 mils of ammonium oxalate T.S., followed by 5 drops of methyl orange T.S., and afterward by ammonia water (previously diluted with two volumes of distilled water), added slowly in small portions, stirring constantly, until the liquid has assumed a yellow color. This operation should require about twenty minutes. Allow the liquid to stand for four hours or over night, collect the precipitate on a filter, wash it with hot distilled water, containing 1 per cent. of ammonium oxalate T.S., until the washings, after strongly acidifying with nitric acid, cease to react with silver nitrate T.S. Dissolve the precipitate by pouring 50 mils of warm diluted hydrochloric acid in small portions over the filter, wash the filter with about 100 mils of distilled water, collect the solution of the precipitate and washings in the same beaker, then dilute to 400 mils with distilled water, precipitate, allow to stand, and wash as before, omitting, however, the addition of 5 Gm. of ammonium chloride. Dry the precipitate and filter obtained in the second precipitation and cautiously ignite in a platinum crucible, heating gently at first, gradually increasing the temperature, and finally heating it over a blast lamp for fifteen minutes or longer, if necessary, until of constant weight. Cool the crucible and contents in a desiccator before weighing. The weight of CaO so obtained does not exceed 0.032 Gm., corresponding to not more than 0.8 per cent. (*calcium oxide*).

"**Assay.**—Dissolve 1 Gm. of Magnesium Carbonate in 30 mils of normal sulphuric acid V.S. and determine the residual acid by titrating with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. The amount of normal sulphuric acid V.S. consumed, exclusive of the normal sulphuric acid V.S. corresponding to the calcium oxide found, is not less than 19.44 mils, indicating the presence of not less than 39.2 per cent. of MgO.

"Each mil of normal sulphuric acid V.S. corresponds to 0.02016 Gm. of MgO or to 0.028035 Gm. of CaO." *U. S.*

Pereira states that the *light carbonate*, when examined with the microscope, is seen to consist of an amorphous powder, more or less intermingled with slender prismatic crystals, which appear as if they were eroded or efflorescent; the *heavy carbonate* consists of granules of various sizes, without any traces of the prismatic crystals observed in the former variety.

A solution in carbonic acid water, prepared by passing carbon dioxide into a reservoir containing magnesium carbonate suspended in water, has been introduced into use as a cathartic and antacid. *Dinneford's Magnesia* is a solution of this nature and contains the dissolved magnesia in the form of bicarbonate into which the carbonate is converted by the carbon dioxide under pressure. According to Christison, it contains only nine grains of carbonate in the fluidounce, though alleged to contain twice that quantity. Its taste is more disagreeable than that of the undissolved carbonate. A formula for this preparation has been introduced into the British Pharmacopœia, with the name of *Liquor Magnesii Bicarbonatis* (see page 647).

Magnesium carbonate may contain an alkaline carbonate or sulphate, or both, from insufficient washing; also sodium chloride, alumina, and calcium carbonate. If water boiled with it changes turmeric, an alkaline carbonate is indicated. If barium chloride produces a precipitate in the water, the presence of a sulphate or carbonate is shown, and if silver nitrate produces precipitation, a chloride is indicated. When dissolved in an excess of hydrochloric acid, an excess of ammonia will throw down alumina, which is almost always present in minute quantity, and ammonium oxalate, afterwards added to the filtered chloride solution, will throw down calcium oxalate if lime be present. When the same solution, nearly neutralized, is rendered blue by potassium ferrocyanide, iron is indicated.

Composition.—According to Berzelius, magnesium carbonate of commerce (*magnesia alba*) was a combination of three molecules of magnesium carbonate with one of magnesium hydroxide. According to Phillips, whose analysis agrees with a subsequent one by Fownes, four molecules of the carbonate are combined with

one of the hydroxide and four of water. (*P. J.*, iii, 480.) The formula given by the British Pharmacopœia of 1898 is $3MgCO_3 + Mg(OH)_2 + 4H_2O$; in other words, a combination of three molecules of magnesium carbonate, one of magnesium hydroxide, and four of water. While the U. S. Pharmacopœia IX gives no formula in the text it is written in the molecular weight tables as follows: "Basic (approximately) $(MgCO_3)_4Mg(OH)_2 + 5H_2O$." The composition of this salt varies with the mode of preparation.

Uses.—Magnesium carbonate is antacid, and, by combining with acid in the stomach, becomes generally cathartic. When it undergoes no change in the alimentary canal it produces no purgative effect. Under these circumstances it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid, and, though prone to produce flatulence in consequence of the liberation of its carbon dioxide in the stomach and bowels, and therefore, inferior to calcined magnesia, it sometimes operates favorably, in consequence of this very property, in *sick stomach* attended with acidity. As an antacid, it has the advantages over sodium carbonate of being less irritating and of neutralizing a larger proportion of acid. It is best administered in water or milk. In order that it may be uniformly diffused through water, it should be previously rubbed up with syrup or ginger syrup. Magnesium carbonate is a useful agent for diffusing camphor and the volatile oils through water, in preparing unofficial medicated waters, and is also used with a similar purpose as a diffusing agent in preparing syrups or elixirs.

Dose, as an antacid, five to twenty grains (0.32–1.3 Gm.); as a laxative, one-half to two drachms (2–7.7 Gm.).

MAGNESII OXIDUM. U. S. (Br.)

MAGNESIUM OXIDE, MAGNESIA Mag. Oxid. [Magnesia, U. S. 1890, Calcined Magnesia, Light Magnesia]

(măg-nē'shĭ-ī ŏx'ĭ-dŭm)

"It contains, after ignition, not less than 96 per cent. of MgO (40.32) and not more than 2 per cent. of CaO. It contains not more than 10 per cent. of water. Preserve it in well-closed containers." *U. S.* "Light Magnesia, MgO, is prepared by exposing Light Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Levis, *Br.;* Calcined Magnesia; Magnesia Calcinata; Magnésie calcinée, *Fr. Cod.;* Magnésie, *Fr.;* Magnesia Usta, *P. G.;* Gebrannte Magnesia, *G.;* Ossido di magnesio, *It.;* Oxido magnesico, *Sp.*

In the British Pharmacopœia, 1885, directions were given for preparing two forms of magnesia, one called *Magnesia Levis,* or *Light Magnesia,* from the *Light Carbonate,* and the other *Magnesia Ponderosa,* from the *Heavy Carbonate.* It is the former which corresponds with our ordinary magnesia. Neither Pharmacopœia gives a detailed process. "Take of Light Carbonate of Magnesium, *four ounces.* Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity, taken from the centre of the crucible, cooled, moistened with water, and dropped into warm diluted sulphuric acid, causes no effervescence." *Br.,* 1885.

By exposure to a red heat, the water and carbon dioxide of the magnesium carbonate are expelled, and the earth is obtained pure. According to Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent., of which from 15 to 20 per cent. is water:

$$(MgCO_3)_4 + Mg(OH)_2 + 5H_2O = 5MgO + 6H_2O + 4CO_2$$

About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbon dioxide. (Duncan.) A more certain indication, however, is the absence of effervescence when hydrochloric acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbon dioxide, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to insure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible, and, as in consequence of its lightness it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk; but the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression. The official direction, to keep the magnesia, after it has been prepared, in well closed vessels, is founded on the fact that it absorbs carbon dioxide and water from the air, but, as the absorption of the gas goes on very slowly, and that of water does not injure the preparation, the caution is often neglected. (See *P. J.*, 1898, 389.) The great bulk of the oxide renders its introduction into small bottles inconvenient. A four ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration, and four times the quantity may be thus pressed into the same space. The density of *Henry's Magnesia,* which is at least four times that of the oxide prepared in the ordinary way, has been ascribed to this method of preparation. It has also been attributed to the influence of intense heat employed in the calcination. The conjecture has even been advanced, that this magnesia, which

has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of magnesium sulphate by potassium hydroxide, as the product afforded by this plan is comparatively dense. It is asserted that the magnesia prepared from the carbonate procured by precipitating magnesium sulphate with potassium carbonate is softer to the touch and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in such magnesia of a little potassium sulphate, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica, which originally existed in the potassium carbonate employed to decompose the magnesium sulphate, and of which sodium carbonate is destitute. According to Richard Phillips, Jr., if equivalent quantities of crystallized magnesium sulphate and crystallized sodium carbonate be boiled together in water, the mixture evaporated to dryness, the residual salts calcined, and the sodium sulphate dissolved out by water, the magnesia obtained will be dense. (See *A. J. P.*, xvi, 118.) By packing the carbonate closely in the crucible, or by moistening and then compressing it strongly in a cloth, before calcination, a heavy magnesia is obtained. The advantages of Henry's magnesia, independently of the convenience of its less bulk, are its greater softness and more ready miscibility with water. A preparation similar to Henry's was originated by T. J. Husband, of Philadelphia. In reference to the preparation of heavy magnesia, T. H. Barr, after trying various methods, obtained the best results either by precipitating a hot concentrated solution of magnesium sulphate with a like solution of sodium carbonate, or by decomposing magnesium chloride by heat. (*A. J. P.*, xxvi, 193.) P. E. Alessandri proposes the following method, which is both simple and rapid, for preparing heavy magnesia. Take ordinary calcined magnesia, free from carbonate, moisten it, in a mortar, with pure absolute alcohol, and triturate it, at first gently, afterwards with some force, but not rapidly. During the agitation, the magnesia is to be moistened three or four times with fresh portions of the alcohol, and the operation is suspended when the bulk of the magnesia appears to remain stationary. Then remove the mass, dry it, rub it to powder, and pass it through a sieve. The product occupies only about one-fifteenth of the original bulk; but it is too expensive for practical uses. (*N. R.*, March, 1882.)

Properties.—Magnesium oxide or magnesia is a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2.3. It was deemed infusible until melted by means of the oxyhydrogen blowpipe of Hare. When sufficiently heated, it conducts electricity and shines with an intense light, which fact is utilized in the Nernst lamp. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature, producing thereby the hydroxide $Mg(OH)_2$. It is almost insoluble, requiring, according to Fyfe, 5142 parts of water at 15.5° C. (60° F.), and 36,000 parts of boiling water, for solution. Water thus impregnated has no effect on vegetable colors, but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one atom of magnesium and one of oxygen. It is officially described as "a white, very bulky, and very fine powder, without odor, and having an earthy, but not a saline taste. On exposure to the air, it slowly absorbs moisture and carbon dioxide. Magnesium Oxide is almost insoluble in water; insoluble in alcohol; dissolved by dilute acids. A solution of Magnesium Oxide in diluted hydrochloric acid, mixed with ammonium chloride T.S. and an excess of ammonia water, yields with sodium phosphate T.S. a white crystalline precipitate. Heat to boiling 1 Gm. of Magnesium Oxide with 50 mils of distilled water, and, after cooling, filter; the filtrate is not more than faintly alkaline to litmus, and when evaporated to dryness leaves not more than 0.02 Gm. of residue (*soluble salts*). Heat to boiling, a mixture of 0.1 Gm. of Magnesium Oxide with 5 mils of distilled water, and, after cooling, pour it into 5 mils of acetic acid. Solution takes place without the evolution of more than a few isolated gas bubbles (*carbonate*). Dissolve 1 Gm. of Magnesium Oxide in 50 mils of diluted hydrochloric acid and 200 mils of distilled water. The solution is colorless, and a 20 mil portion does not give an immediate blue coloration upon the addition of several drops of potassium ferrocyanide T.S. (*iron*). Dissolve 0.5 Gm. of Magnesium Oxide in a slight excess of diluted hydrochloric acid and dilute with distilled water to 25 mils. Ten mils of this solution does not respond to the Test for heavy metals (see Part III, Test No. 3). Transfer to a porcelain crucible about 1 Gm. of Magnesium Oxide, weigh accurately, and expose it to a low red heat; it loses not more than 10 per cent. of its weight (*water*). To test for calcium proceed as directed under *Magnesii Carbonas*, using about 1.5 Gm. of recently ignited Magnesium Oxide, accurately weighed. It shows not more than 2 per cent. of CaO." *U. S.*

"A white powder differing only from 'Magnesia Ponderosa' in its bulk, the volumes corresponding to the same weight having the ratio of three and a half to one." *Br.*

"**Assay.**—Dissolve about 0.5 Gm. of Magnesium Oxide, which has been recently ignited to constant weight and accurately weighed, in 30 mils of normal sulphuric acid V.S. and determine the residual acid by titrating with normal potassium hydroxide V.S., using methyl orange T.S. as indicator. The amount of normal sulphuric acid V.S. consumed, exclusive of the normal sulphuric acid V.S. corresponding to the calcium oxide found, when calculated to 1 Gm. of the ignited Magnesium Oxide, is not

less than 47.62 mils, indicating the presence of not less than 96 per cent. of MgO.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.02016 Gm. of MgO or to 0.028035 Gm. of CaO." *U. S.*

Magnesium is a white, very brilliant metal, of sp. gr. 1.75, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. It burns with great facility, and yields by its combustion a light which is intensely white and very rich in actinic, or chemically active, rays, so that it finds wide application in signal lights and for photography. Many of the so-called "flash powders" contain metallic magnesium in a finely divided state as their basis. There is a magnesium hydroxide, possessing the formula $Mg(OH)_2$, which is the basis of the Magma Magnesiæ. With nitric and hydrochloric acids magnesium forms salts which are soluble in alcohol and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydroxide, and by potassium and sodium carbonates as a carbonate, but it is not precipitated by the alkaline bicarbonates, nor by common ammonium carbonate.

Magnesia is liable to contain, as impurities, magnesium carbonate, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. Lime, which is a very frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste, is detected by ammonium oxalate or potassium bicarbonate. Neither of these salts disturbs a neutral solution of pure magnesium salts, but if lime is present, both produce a precipitate, the former of calcium oxalate, the latter of calcium carbonate. According to Wittstein, calcium oxalate is soluble in the neutral salts of magnesium, requiring 50 parts of magnesium chloride, and 90 of magnesium sulphate, and consequently there might be no precipitate, or one redissolved by the liquid, should the proportion of lime be very small. (*J. P. C.*, 4e sér., iii, 216.) On this account a special method of determining small amounts of calcium salts has been introduced into the texts of magnesium oxide and magnesium carbonate of the U. S. P. IX.

Uses.—Magnesium oxide is used in medicine chiefly for its antacid properties. In cases of *gastric hyperacidity*, whether due to overactivity of the acid-secreting glands of the stomach or to fermentative changes in the foodstuff, it is one of the best correctives that we have. It has the advantages over bicarbonate of soda that it is less irritating to the mucous membrane, that it does not evolve any gas, and that the dose required is smaller. One grain of magnesium oxide has about the same neutralizing power as four grains of sodium bicarbonate. When given in large enough dose it exercises a laxative effect. This aperient action is due to the union of the magnesium with the acids of the primæ viæ. When it meets with no acid, it is apt to linger in the stomach or bowels, and should in that case be followed by lemonade. It may be administered in water or milk, and thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form a more or less concrete mass, owing to the production of a hydroxide. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. In this connection Duncan recommends boiling the magnesia for a few moments with half the quantity of water prescribed to prevent subsequent caking. It has been conjectured that anhydrous magnesia might prove injurious to the stomach by solidifying its liquid contents, and the oxide which has become saturated with moisture by exposure to a damp air is preferably recommended. Freshly precipitated magnesium hydroxide will serve as an antidote to arsenic trioxide, though less efficient than ferric hydroxide. The experiments of Carles have shown that the soluble *magnesium saccharate* is not superior as an antidote for arsenic to simple magnesia. Ohleyer (*L. L.*, July, 1873) employs magnesia as a dressing in *ulcers* and *abrasions*, while Vergley recommends for *burns* calcined magnesia triturated with milk so as to form a paste, which should be applied thickly several times a day.

Dose, as an antacid, five to twenty grains (0.32–1.3 Gm.); as a laxative, one-half to one drachm (2–3.9 Gm.).

MAGNESII OXIDUM PONDEROSUM. U. S. (Br.)

HEAVY MAGNESIUM OXIDE Mag. Oxid. Pond.
[Heavy Magnesia Magnesia Ponderosa, Pharm. 1890]

(măg-nē′shĭ-ĭ ŏx′ĭ-dŭm pŏn-dẹ-rō′sŭm)

"It contains, after ignition, not less than 96 per cent. of MgO (40.32) and not more than 2 per cent. of CaO. It contains not more than 10 per cent. of water. Preserve it in well-closed containers." *U. S.* "Heavy Magnesia, MgO, is prepared by exposing Heavy Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Ponderosa, *Br.*, Heavy Calcined Magnesia; Oxide of Magnesium; Magnésie Calcinée pesante, *Fr.*; Schwere gebrannte Magnesia, *G.*

This was directed, in the British Pharmacopœia, 1885, to be prepared precisely in the same manner as light magnesia, using, however, the heavy carbonate (Heavy Magnesium Carbonate, *Br.*). "Heavy Magnesium Oxide is a white, dense, and very fine powder, which conforms to the reactions and tests under *Magnesii Oxidum.*" *U. S.* It is described by the Br. Ph., as "a white powder, insoluble in *water*, but readily dissolved by acids, the solution yield-

ing the *reactions* characteristic of magnesium. Yields no characteristic *reactions* for aluminium and copper, and not more than the slightest *reactions* for iron, calcium, carbonates, and sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Loses not more than 1 per cent. of its weight when heated to dull redness." *Br.*

The two varieties of light and heavy magnesia differ only in their weight in the same bulk, the volumes corresponding to the same weight being to each other in the ratio of three and one-half to one. (See *Magnesii Oxidum*, page 674.)

Dose, five to sixty grains (0.32–3.9 Gm.).

Magnesium Sulphate is a constituent of sea water, and of some saline springs. It also occurs native, either crystallized in slender, prismatic, adhering crystals, or as an efflorescence on certain rocks and soils which contain magnesia and a sulphate or sulphide. In the United States it is found in the great caves so numerous to the west of the Allegheny Mountains. In one of these caves, near Corydon in Indiana, it formed a stratum on the bottom several inches deep, or appeared in masses sometimes weighing ten pounds, or disseminated in the earth of the cavern, one bushel of which yielded from four to twenty-five pounds of the sulphate. It also appeared on the walls of the cavern, and, if it was removed, acicular crystals again appeared in a few weeks. (Cleveland.)

Under the name of *kieserite*, a mineral is obtained from the saline deposits at Stassfurt, in Germany, which consists chiefly of impure magnesium sulphate. It is used as a source for preparing magnesium sulphate, and is exported from Germany; for a historical paper on Epsom salt by M. I. Wilbert, see *Proc. A. Ph. A.*, 1904, 351.

Magnesium sulphate was originally procured by evaporating the waters of saline springs at Epsom, in England. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine remaining after the crystallization of common salt from sea water furnished by careful evaporation precisely the same salt, and, as this was a much cheaper product, it superseded the former. The residual brine, or bittern, consists of magnesium sulphate and magnesium and calcium chlorides. As the magnesium sulphate crystallizes first, it may with proper care be obtained nearly pure, although most frequently the salt prepared in this way is deliquescent from the presence of magnesium chloride. It may be freed from this impurity by washing the crystals with their own saturated solution. It was from this source that the greater part of the Epsom salt of commerce was long obtained in Europe. The salt works of New England supplied our own market with an impure and deliquescent sulphate. With the improvements of chemistry, other and better processes have been adopted. In the neighborhood of Genoa and Nice, magnesium sulphate is prepared in large quantities from a schistose rock containing magnesia and iron sulphide. The mineral is roasted, and exposed in heaps for some months to the action of air and water. It is then lixiviated, the ferrous sulphate decomposed by lime water, and the salt obtained pure by repeated solution and crystallization.

William Henry, of Manchester, whose calcined magnesia became famous throughout the world, took out a patent for a mode of preparing magnesia and its salts from the double magnesium and calcium carbonate—the *dolomite* of mineralogists. His process was to drive off the carbon dioxide by heat, and to convert the residue into hydroxide. He treated this with a sufficient quantity of hydrochloric acid to dissolve out the calcium hydroxide, and then converted the magnesia which remained into a sulphate either by sulphuric acid or by ferrous sulphate.

The salt was extensively manufactured in Baltimore and Philadelphia from a silicious magnesium hydroxide. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighborhood of Baltimore and in the southern counties of Pennsylvania. The advantage which it possesses over the dolomite, in the preparation of this salt, is the almost entire absence of lime, owing to which there is little or no waste of acid, and the operation is much simplified. The mineral is reduced to a fine powder and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert any ferrous sulphate which may be present into ferric oxide. It is then dissolved in water, and calcium sulphide added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared by this process is generally very pure and clean, although it sometimes contains a trace of ferrous sulphate. A very pure magnesium sulphate free from chlo-

ride is obtained as a by-product in the manufacture of carbon dioxide from magnesite when sulphuric acid is used to decompose the carbonate. This industry at one time assumed large proportions because of the demand for liquefied carbon dioxide in the manufacture of aerated and effervescing mineral waters. In the modern method of making carbon dioxide, however, acid is not used, the CO_2 being evolved by simply heating the magnesite (magnesium carbonate) to a little over 300° C. (572° F.). Magnesium sulphate is also obtained from *kieserite* from the Stassfurt mines, Germany.

Properties.—Magnesium sulphate is in "small, colorless, prismatic needles or rhombic prisms, without odor, and having a cooling, saline, and bitter taste; slowly efflorescent in the air. One Gm. of Magnesium Sulphate dissolves in 1 mil of water at 25° C. (77° F.); also in about 0.2 mil of boiling water; almost insoluble in alcohol at 25° C. (77° F.). An aqueous solution of the salt (1 in 20) is neutral to litmus. When exposed to warm air, the salt loses some of its water of crystallization and is converted into a white powder. Further heating removes more water, and at a temperature somewhat above 200° C. (392° F.) it is rendered anhydrous. An aqueous solution of the salt (1 in 20), when mixed with ammonium chloride T.S. and ammonia water, yields with sodium phosphate T.S. a white, crystalline precipitate. An aqueous solution (1 in 20) yields with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. Add a few drops of silver nitrate T.S. to 10 mils of an aqueous solution of the salt (1 in 20), previously mixed with a few drops of nitric acid; not more than an opalescence is produced (*chloride*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1)." *U. S.*

"In small, colorless, transparent, rhombic prisms. Taste bitter. Soluble in 1 part of *water.* Yields the *reactions* characteristic of magnesium and of sulphates. When 0.5 gramme is dissolved in 50 millilitres of *water,* and to the solution 20 millilitres of *solution of ammonium chloride,* 20 millilitres of *strong solution of ammonia,* and excess of *solution of sodium phosphate* are added in succession, the mixture, after well stirring and setting aside for twelve hours, yields a precipitate which, when collected, washed with *strong solution of ammonia* diluted with three times its volume of *water,* dried and heated to redness, weighs not less than 0.220 and not more than 0.226 gramme. Yields no characteristic *reactions* for zinc, and not more than the slightest *reactions* for chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million. 10 grammes dissolved in 20 millilitres of *water,* and heated on a water-bath for one hour in a closed flask, yield a clear, colorless solution (absence of insoluble impurities and of more than traces of iron)." *Br.*

"**Assay.**—Dissolve about 1 Gm. of Magnesium Sulphate, accurately weighed, in 100 mils of distilled water, gradually add to the solution, with constant stirring, an excess of sodium phosphate T.S. (about 20 mils), allow to stand for ten minutes, then add 30 mils of ammonia water and allow to stand for four hours. Collect the precipitate on a filter, wash it with dilute ammonia water (1 volume of ammonia water to 3 volumes of distilled water) until 10 mils of the washings, when acidulated with hydrochloric acid, yields no turbidity on the addition of a few drops of barium chloride T.S. Dry and ignite to constant weight. The weight of the magnesium pyrophosphate so obtained corresponds to not less than 48.59 per cent. nor more than 53.45 per cent. of $MgSO_4$.

"Each gramme of Magnesium Sulphate corresponds to not less than 0.4495 Gm. nor more than 0.4944 Gm. of magnesium pyrophosphate ($Mg_2P_2O_7$)." *U. S.*

It usually occurs in small acicular crystals, which are produced by agitating the solution while crystallizing. It slowly effloresces in the air. Exsiccated magnesium sulphate is employed in some localities under the title *Magnesium Sulphuricum Siccum.* It is a fine white powder of which about 65 parts represents 100 parts of the crystallized salt.

Magnesium sulphate is completely decomposed by potassium and sodium hydroxides and their carbonates, by lime, barium and strontium oxides, and their soluble salts. Ammonia partially decomposes it, and forms with the remainder a double sulphate. Potassium and sodium bicarbonates do not decompose it, except by the aid of heat. An economic use which has been recommended of magnesium sulphate is the addition of a strong solution to ordinary white-wash, whereby a beautiful whiteness may be given to walls and ceilings. A little of it, moreover, added to starch considerably increases its stiffening properties, and at the same time in some degree resists the action of fire. (*Chem. News,* April, 1867.)

Uses.—Magnesium sulphate is an active cathartic operating with but little pain or nausea, and producing watery stools. Its cathartic action is due in part to its attraction for water, but it seems also to exercise a direct stimulant effect upon the glands of the intestinal tract. It has but little direct effect upon peristalsis, the increased movements of the intestinal muscles being due chiefly to the over distention with the fluid. It may be used whenever it is desired to clean out the alimentary canal, especially when a prompt action is desired, as in cases of *poisoning* or certain types of *acute enteritis.* It is a valuable remedy when it is desired to encourage the elimination of metabolic poisons through the bowel, as in *gout* or *uremia.* It is also highly esteemed for the evacuation of *dropsical effusions.* As an habitual laxative, although widely used, it is generally inferior to the vegetable cathartics.

When injected into the circulation magnesium

sulphate acts as a violent poison, lessening respiration and depressing the circulation by a direct action upon the heart. It also paralyzes the peripheral ends of the motor nerves and, according to Meltzer and Auer (*A.J.Phys.*, 1905, xiv, p. 366, and xvii, p. 313), also the sensory nerves. Guthrie and Ryan (*A. J. Phys.*, 1910, xxiv, p. 329) dispute the conclusions of Meltzer and Auer that it has a true anesthetic action, believing that the apparent anesthesia is due to the motor paralysis, but the experiments of Wiki (*A. I. P. T.*, 1911, xxi, p. 415) seem to demonstrate that when applied locally it is a paralyzant to the sensory nerves. As an internal remedy it has been employed by intraspinal injection as an anesthetic and in the treatment of *tetanus*. Its action in tetanus appears to be solely that of an anticonvulsant, not a true curative, and whether it has any superiority over other methods of controlling the convulsions is at present uncertain. As an antitetanic fifteen to thirty grains (1–2 Gm.) may be injected daily into the subarachnoid space in 10 per cent. solution. For intraspinal anesthesia, although it has been used with apparent success in a few cases, it appears to have no advantage over the cocaine series and has shown itself distinctly irritant to the kidney.

As Christison reported the case of a boy ten years old who was said to have been killed by two ounces of the salt without the induction of purgation, it is possible that, under some circumstances, when very large amounts of magnesium sulphate are given by the mouth, sufficient may be absorbed to produce poisonous effects.

It is also used locally in saturated solution for its anesthetic effect in *sprains* and *bruises*, and appears to be possessed of some sort of antiphlogistic action. Tucker (*T. G.*, 1907) has used it with favorable results as a topical application in *erysipelas, cellulitis, epididymitis*, and other localized inflammatory conditions.

Dose, one to eight drachms (3.9–31 Gm.).

MAGNESII SULPHAS EFFERVESCENS. Br.

EFFERVESCENT MAGNESIUM SULPHATE

(măg-nē'şĭ-ī sŭl'phăs ĕf-fẹr-vĕs'cẹnş)

Magnesium Sulphuricum Effervescens; Magnesiæ Sulphas Effervescens; Effervescent Sulphate of Magnesia; Effervescent Epsom Salt; Brausendes Magnesiumsulfat, *G.;* Sulfato magnesico effervescente, *Sp.*

This preparation was dropped from the U. S. P. IX. The process of U. S. P. VIII is appended.

* "Magnesium Sulphate, uneffloresced crystals, *five hundred grammes* [or 17 ounces av., 279 grains]; Sodium Bicarbonate, dried and powdered, *four hundred and three grammes* [or 14 ounces av., 94 grains]; Tartaric Acid, dried and powdered, *two hundred and eleven grammes* [or 7 ounces av., 193 grains]; Citric Acid, uneffloresced crystals, *one hundred and thirty-six grammes* [or 4 ounces av., 349 grains]; to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dry the magnesium sulphate on a water-bath, until it ceases to lose weight, then, after powdering the dry salt, mix it intimately with the citric acid, which has previously been powdered, and the tartaric acid, and thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture has acquired a moist consistence by the aid of careful manipulation with a wooden spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles."

"Magnesium Sulphate, in crystals, 500 *grammes;* Sodium Bicarbonate, in powder, 360 *grammes;* Tartaric Acid, in powder, 190 *grammes;* Citric Acid, in powder, 125 *grammes;* Refined Sugar, in powder, 105 *grammes*. Dry the Magnesium Sulphate at about 55° C. (131° F.) until it has lost twenty-three per cent. of its weight; powder the dried product; mix it with the Refined Sugar and then with the other ingredients. Place the mixture in a dish or pan of suitable form heated to between 90° and 105° C. (194° and 221° F.). When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. (131° F.). The product weighs about one thousand *grammes*." *Br.*

This effervescent salt is intended to furnish a less disagreeable form of administering Epsom salt. Although it represents only 50 per cent. of magnesium sulphate, it is almost equally active, both the sodium tartrate and citrate which are formed being laxative.

Dose, from two drachms to one ounce (7.7–31 Gm.).

MALTUM. U. S.

MALT

(măl'tŭm)

"The grain of one or more varieties of *Hordeum sativum* Jessen (Fam. *Gramineæ*), partially germinated artificially, and then dried at a temperature not exceeding 55° C. (131° F.). It is capable of converting not less than 5 times its weight of starch into sugars. Protect it from heat and moisture." *U. S.*

Maltum Hordei; Barley Malt; Malt d'Orge, *Fr.;* Gerstenmalz, Malz, *G.*

Preparation.—Malt is prepared on an enormous scale for brewing purposes in all parts of the world where the climate is suited to the

growth of barley. The object of the process for making malt, commonly known as malting, is to allow germination of grain to go just far enough to develop the maximum amount of *diastase,* the ferment by which the starch is converted into sugar, which may afterwards undergo the alcoholic fermentation during the process of brewing. In order to achieve this, the barley is first *steeped—i.e.,* allowed to remain one or two days in cold water, of which it absorbs from 10 to 50 per cent.; second, *couched—i.e.,* thrown into heaps upon a floor and allowed to develop heat and germinate; third, when the *acrospire* or shoot is one-third the length of the grain, the latter is *floored—i.e.,* spread upon wide floors to dry; fourth, *kiln-dried—i.e.,* exposed to such a temperature as thoroughly to dry it and kill the young plant. If the temperature be raised high enough to scorch the grain, it becomes *Amber Malt,* or *Black Malt,* according to the extent of the caramelizing; only the light colored varieties of malt are suitable for pharmaceutical purposes, the black varieties being practically devoid of diastatic value and being used for coloring mainly. Besides the diastase, a second soluble ferment is formed during the malting process, the so-called *peptase,* which in the after-mash process changes the proteids of the malt into peptones and parapeptones which give nutritive value to the beer. Malt contains an alkaloid *hordenine* ($C_{10}H_{15}ON$); for a description of the physiological properties, see Part II.

Malt is now frequently germinated by what is called the pneumatic system in which the operation is carried out in large perforated iron drums which are caused to revolve very slowly, and in which the temperature is carefully regulated by ventilating fans. Another mechanical system of malting which is extensively used in some countries, especially in France, is based upon the principle of the ordinary conveyor, a separate section being used for each day that the germination lasts.

The commercial value of a sample of malt is determined by its diastatic power and also by its content of aqueous extract estimated under specified conditions. Between one-half and three-fourths of malt is soluble in cold water.

Properties.—It is composed of germinated grains with the radicles and acrospires adhering, and is officially described as follows: "Yellowish or amber-colored grains; crisp when fractured, the interior surface nearly white. It has an agreeable, characteristic odor, and a sweet taste due to the conversion of the starch in the seed into maltose, through the action of diastase. Malt floats in cold water. For the subsequent tests, prepare an infusion as follows: Mix 10 Gm. of Malt in No. 12 powder, with 100 mils of distilled water and maintain the mixture at a temperature of from 50° to 55° C. (122°–131° F.) for one hour with occasional stirring. Place it upon a filter and when the liquid has passed through, wash the contents of the filter with distilled water, in small portions, until the combined infusion and washings measure 200 mils. The weight of the solid soluble constituents of Malt, obtained by evaporating to dryness on a water bath an aliquot portion of the freshly prepared, aqueous infusion, and subsequently drying it for one hour at 100° C. (212° F.) in an air bath, corresponds to not less than 70 per cent. of the Malt taken. The acidity of Malt (calculated as lactic acid) does not exceed 0.3 per cent. as determined by titrating an aliquot portion of the freshly prepared infusion with tenth-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator. Each mil of tenth-normal potassium hydroxide V.S. used corresponds to 0.009 Gm. of lactic acid.

"**Assay.**—To determine the starch converting power of Malt, proceed as directed under *Diastasum,* page 403, using 20 mils of the fresh infusion of malt, prepared as directed above, in place of the quantity of solution of diastase there directed." *U. S.*

Uses.—Malt is not itself used directly in medicine, but is official as the basis of Malt Extract. From it are also prepared the so-called *Malt Liquors* by making an infusion (*wort*) of the bruised malt, adding hops and various other substances, and fermenting. *Ale, brown stout,* and *porter* are made by rapid fermentation at a comparatively high temperature 23.8° C. (75° F.), while *lager beer* is prepared by a very slow, prolonged fermentation at a low temperature.

Off. Prep.—Extractum Malti, *U. S.*

MANGANI DIOXIDUM PRÆCIPITATUM. U. S.

PRECIPITATED MANGANESE DIOXIDE Mangan. Diox. Præc. [To Replace Mangani Dioxidum, U. S. 1890]

(măn'gą-nī dī-ŏx'ĭ-dŭm præ-cĭp-ĭ-tā'tŭm)

"It consists chiefly of manganese dioxide [$MnO_2 = 86.93$] with small amounts of other oxides of manganese, corresponding to not less than 80 per cent. of MnO_2." *U. S.*

Manganese Peroxide, *Br., Appendix;* Manganum Hyperoxydatum; Oxydum Manganicum; Peroxide of Manganese; Deutoxide of Manganese, Black Oxide of Manganese, Pyrolusite; Oxyde (Bi-) de Manganèse, *Fr. Cod.;* Oxyde noir de Manganèse, *Fr.;* Braunstein, *G.;* Biossido di manganese, *It.;* Manganesa, Pyrolusita, *Sp.*

The U. S. P. IX omitted a process for its manufacture, but the U. S. P. VIII process was as follows:

* "Manganese Sulphate, *fifty grammes* [or 1 ounce av., 334 grains]; Ammonia Water, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Solution of Hydrogen Dioxide, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Distilled Water, *a sufficient quantity.* Dissolve the manganese sulphate in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of distilled water. Dilute the ammonia water with an equal volume of distilled water, and mix it with the solution of hydrogen dioxide, which has

also been diluted with an equal volume of distilled water. Pour the mixed solutions, slowly, with constant stirring, into the solution of manganese sulphate. Allow the mixture to stand for one hour, stirring frequently. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by affusion and decantation with hot distilled water, using *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] each time. Collect the precipitate on a plain filter, and continue the washings with hot distilled water until the washings no longer have an alkaline reaction upon red litmus paper, and produce no turbidity when mixed with barium chloride test solution. Allow the precipitate to drain, then dry it at 150° C. (302° F.)." *U. S. VIII.*

The official precipitated manganese dioxide of the U. S. P. (8th Rev.) is prepared from manganous sulphate by the simultaneous action of ammonium hydroxide (which precipitates manganese hydroxide), and of hydrogen dioxide, which oxidizes this at once into the hydrated manganese dioxide. This precipitate, after thorough washing, is dried at 150° C. (302° F.), so that there remains MnO_2 as the final product.

A change was made in the U. S. P. VIII, and a process for preparing manganese dioxide was introduced; this was due to the fact that it has become very difficult to obtain native manganese dioxide of good quality; the precipitated manganese dioxide is, of course, more expensive than the native oxide, but much to be preferred in making pharmaceutical preparations. There is no method officially directed in the U. S. P. IX.

Metallic manganese was discovered by Scheele and Gahn in 1774, and is obtained from the native black oxide by intense ignition with charcoal. As obtained by C. Brunner, manganese is brittle, grayish-white, and very hard, being capable of cutting glass and scratching the best tempered steel. It is susceptible of the most perfect polish, and in the form of a fine powder decomposes water at a boiling temperature. Its sp. gr. is about 7.9.

Deville obtained the metal by heating the black oxide with charcoal in excess in a lime crucible. The metal thus obtained is more refractory than iron, while that procured by Brunner fused at the same heat as white cast iron. Greene and Wahl have lately succeeded in getting the metal in large masses by the reduction of the ores with the aid of silicon, which they add in the form of an iron silicide. The atomic weight of manganese is 54.93. With oxygen it forms five and possibly seven compounds: MnO, Mn_2O_3, Mn_3O_4, MnO_2, and Mn_2O_7. The *monoxide* is of a light green color, and is the oxide present in, or corresponding to, manganous salts. The *sesquioxide* is black or dark brown, when in the hydrated state; the *magnetic oxide*, Mn_3O_4, is red; the dioxide is black; and the permanganic oxide, Mn_2O_7, is, when in the free state, a very unstable dark reddish-brown liquid. The monoxide is a stable base, the sesquioxide is feebly basic, and the dioxide when acted upon by acids yields manganous salts, while oxygen is evolved. The highest oxide is acid-forming yielding permanganic acid, $HMnO_4$, the salts of which are known as permanganates. (See *Potassii Permanganas.*) There exists also an acid, H_2MnO_4 (*manganic*), of which the salts formed are called manganates. The oxide corresponding is not known, however. Metallic manganese is an occasional constituent of organic matter. It has been detected in minute quantity in bone, hair, brain, epidermis, gastric juice, bile, urine, and pus, and has been found by Millon and others in the blood. Glénard of Lyons, denies that it is a normal constituent of the blood, although sometimes present, but the evidence of numerous experimenters shows that it generally exists in that fluid, and when not detected it may be because the quantity present is too minute to be easily discovered. According to E. Davy, potassium hydroxide, dissolved in an equal weight of water, forms a delicate test for manganese, not obscured by the presence of other metals. The smallest portion of matter suspected to contain the metal, being finely pulverized or in solution, is placed upon a slip of silver foil, and a drop of the test added. Upon evaporation to dryness with a spirit lamp, and raising the heat, the characteristic green potassium manganate will appear on the foil. (*Chem. Gaz.*, March 15, 1854.) Manganese is a constituent of all arable land, and is found in the ashes of most of the vegetables which form the food of man and the inferior animals. In the mineral kingdom it occurs sometimes as silicate (*rhodonite*) or carbonate (*diallogite* and *rhodocrosite*), and very abundantly as the black oxide, or dioxide, called *pyrolusite* or other oxides (*hausmannite* and *braunite*). The latter mineral was formerly the British official oxide. It is now in the Appendix of the British Pharmacopœia and is defined as follows: "Manganese Peroxide, MnO_2, the powdered native pyrolusite."

But few mines of manganese dioxide exist, though the metal itself is very generally diffused throughout the mineral kingdom. It occurs most abundantly in the Russian Caucasus, which furnishes nearly half of the annual production of the world, in Chili, Cuba, Great Britain, Turkey, and Australia. In the United States it occurs in largest amount at Crimora, Va., Cartersville, Ga., and Batesville, Ark.; other isolated localities exist in California, Utah, Alabama, and Tennessee. The amount of manganese ore mined in the United States is at present very small, being only 3146 tons in 1904, although large quantities of manganiferous iron ores, manganiferous silver ores and manganiferous zinc residues are obtained, which go into the manufacture of spiegeleisen and ferro-manganese. On the other hand, very pure manganese ore is imported chiefly from the Caucasus, the amount in 1905 having been 257,033 tons. It comes packed in casks or barrels, gen-

erally in lumps and coarse powder, just as it is dug out of mines, though occasionally it is received from England in a pulverized condition. It is a good rule to buy it unpowdered, as its quality can be better judged in that state. A dark shining crystalline appearance is an indication of good quality, although an assay will alone determine its quality with certainty.

Properties.—Manganese dioxide, as it occurs in nature, is very diversified in its appearance. Its sp. gr. varies from 4.7 to 4.9. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having the metallic luster, but far more frequently in the form of a dull earthy-looking substance of a black or brown color. It is purest when crystallized. As it occurs in commerce, it is usually in the form of a black powder, insoluble in water, and containing more or less oxidized iron, calcium carbonate, barium sulphate, and earthy matter. Iron, which is rarely absent, is detected by the production of a green or blue tint on the addition of potassium ferrocyanide to its hydrochloric acid solution. When exposed to a red heat it yields a portion of its oxygen, and is reduced to manganoso-manganic oxide. Hence its use in obtaining that gas. Good samples, after being dried, lose, when heated to whiteness, 12 per cent. of oxygen. It is distinguished from antimony sulphide which it physically resembles by its infusibility, and by causing the evolution of chlorine on being heated with hydrochloric acid. When of a brown color, it is not of good quality.

The U. S. Pharmacopœia describes the precipitated manganese dioxide as "a heavy, very fine, black powder, without odor or taste; permanent in the air. It is insoluble in water or alcohol. When heated with hydrochloric acid, it is converted into manganous chloride and chlorine is evolved. At a red heat Precipitated Manganese Dioxide gives off oxygen and is converted into reddish-brown manganous-manganic oxide (Mn_3O_4). Add 2 drops of hydrochloric acid to about 0.1 Gm. of Precipitated Manganese Dioxide contained in a test tube, boil the mixture for one minute with 0.5 Gm. of lead peroxide and 5 mils of nitric acid and then add 5 mils of distilled water; the liquid assumes a reddish-violet color. Add 20 mils of distilled water to 1 Gm. of Manganese Dioxide and 2 Gm. of oxalic acid, follow this by 3 mils of sulphuric acid, and digest the mixture for several hours on a water bath; not more than 0.2 per cent. of residue remains (*insoluble substances*).

"**Assay.**—Dissolve about 0.2 Gm. of Precipitated Manganese Dioxide, accurately weighed, in a mixture of 50 mils of tenth-normal oxalic acid V.S. and 3 mils of sulphuric acid, heat to 80° C. (176° F.) on a water bath, and titrate the residual oxalic acid with tenth-normal potassium permanganate V.S. It shows not less than 80 per cent. of MnO_2.

"Each mil of tenth-normal oxalic acid V.S. used corresponds to 0.0043465 Gm. of MnO_2. Each gramme of Precipitated Manganese Dioxide corresponds to not less than 184 mils of tenth-normal oxalic acid V.S." *U. S.*

Uses.—Because manganese has been found to be a normal constituent of hemoglobin it was conjectured that it might have a similar effect to iron in restoring impoverished blood, and it was at one time used to a considerable extent in the treatment of various forms of *anemia,* but experience has proven it to be a drug of little or no value in this condition. It appears to possess some stimulant action upon the uterine mucosa and is still used in the treatment of *amenorrhea.* Its ancient employment in *syphilis, scurvy,* and various *skin diseases,* does not appear to be founded on any rational basis. Leared (*Glasgow Med. Journ.,* Jan., 1865) has suggested the use of manganese dioxide for its antacid effects in gastric conditions, such as *pyrosis.*

The native oxide is used in the arts for obtaining chlorine in the manufacture of bleaching powder, for giving a black glazing to pottery, and for freeing glass from the color which it derives from iron. In the laboratory it is employed to obtain oxygen and chlorine, and to form the salts of manganese. It is also used for liberating chlorine from hydrochloric acid and from sodium chloride, and iodine from sodium iodide contained in kelp.

Dose, three to ten grains (0.2–0.65 Gm.).

MANNA. U. S.

MANNA

(măn'nạ)

"The dried saccharine exudation of *Fraxinus Ornus* Linné (Fam. *Oleaceæ*)." *U. S.*

Manne, *Fr. Cod.;* Manna, *P. G., It.;* Mana, *Sp.*

Manna is said to be obtained from several other trees besides *Fraxinus Ornus,* among which *F. rotundifolia, F. excelsior,* and *F. parviflora* have been particularly designated. Many saccharine substances, generally exudations from plants, have, from their resemblance to this substance, obtained the name of manna, and attracted more or less attention from writers. The term "manna" has been applied to certain substances which have no relation to true manna, notably to the lichen *Lecanora esculenta,* which at times has suddenly fallen like rain over immense tracts of country, from Persia to the African Sahara. It occurs in the form of small roundish lumps, from the size of a pin's head to that of a pea, yellowish or grayish externally and whitish within, hard, inodorous, and insipid. It has been affirmed that this lichen does not contain starch, but it is really used as an article of food, and good bread is said to have been made out of it. (*Nature,* Jan., 1891.) It is probable that it is the manna of Scripture.

The proper false mannas, exudations from various trees, are best considered under the headings of the countries which yield them:

European False Manna, or *Briançon Manna,* an exudation from the common European larch

(*Larix europæa,* or *Pinus Larix*), differs chemically from ordinary manna in containing no mannite. Berthelot found in it a peculiar sugar, which he named *melezitose.* (See *A. J. P.,* 1859, p. 61.) To this the formula $C_{18}H_{32}O_{16} + 2H_2O$ is given showing that it belongs to the class of the saccharides.

American False Manna.—A substance resembling manna, of a sweet, slightly bitter and terebinthinate taste, and actively purgative, exudes from incisions in *Pinus lambertiana,* of Oregon, and was used by the natives. Berthelot has extracted from this product a peculiar saccharine principle, which he calls *pinite.* It is very sweet, but does not undergo the vinous fermentation. (See *A. J. P.,* xxviii, 157.) Pinite was for a long time classed among the sugars, but the latest researches seem to show that it is a hexahydric phenol derived from hexahydrobenzene. The formula is $C_{17}H_{14}O_6$, and it is a methyl derivative of inosite.

California Manna, or *Father Picolo's Manna.*—Proust (*Ann. d. Chim.,* 1806, 145) alludes to a manna mentioned by Father Picolo as being deposited on a species of grass in California. J. U. Lloyd (*A. J. P.,* 1897, 337) believes Picolo's manna to be a saccharine deposit, caused by aphides on *Phragmites communis.* It is apparently still collected by the Indians.

African False Mannas.—Turkish Manna is a sweet product obtained from *Echinops persica* Fisch., and is obtained by treating the cocoons of a coleopterous insect (*Larinus maculatus*) with hot water, filtering and crystallizing the sugar. From it Berthelot obtained a new variety of sugar, *trehalose,* $C_{12}H_{22}O_{11} + 2H_2O$. (*Gaz. Méd. de Paris,* 1857.) *Pinus Cedrus,* of Mount Lebanon, yields a similar product, which has some repute in Syria as a remedy in *phthisis.* (*P. J.,* xiii, 411.) In the neighborhood of Diarbekir, in Asiatic Turkey, a saccharine substance, known as *Diarbekir manna,* is found on the leaves of dwarf oaks, from which it appears to be exuded. (*P. J.,* Nov., 1862, p. 546.) The manna of the oak of Kurdistan, spoken of by Flückiger, is probably the same as that of Diarbekir, which may be its entrepôt. According to Flückiger, this consists chiefly (90 per cent.) of a crystallizable sugar. It deviates to the right the plane of polarized light, and reduces in the cold the solution of copper oxide in soda and glycerin. This manna contains a mucilage, but no cane sugar or dextrin. (*J. P. C.,* April, 1873, p. 335.) *Quercus Vallonea* Kotschy, and *Q. persica* Jaub. et Spach, yield "*oak manna,*" through insect agency, while certain species of *Echinops* (probably *E. persica* Fisch.) yield the singular manna-like substance that is known as *Trehala* in Syria and as *Shukkar Tigal* in India. *Pyrus glabra* yields a manna which is collected by the people of Luristan, in Persia. It has long been known that *Salix fragilis* and probably other species of willow yield to the Persians a manna-like exudation. According to Raby (*L'Union Pharm.,* May, 1889), there are two varieties, *chirkhest* and *bidenguébin,* which contain respectively, according to the analysis of Ludwig, *chirkhestite* ($C_6H_{14}O_6$), allied to sorbite, and *bidenguebinose* ($C_{12}H_{22}O_{11}$), allied to melezitose. Whether these mannas are really distinct from those sold in the Indian bazaars as coming from Afghanistan and Persia seems uncertain. Of these bazaar mannas the most important is the *Shirkoit* or *Oriental* manna. By Haussknecht it is referred to *Atraphaxis spinosa;* but J. E. T. Atchison states that it is yielded by the *Cotoneaster nummularia* Fisch. et Mey., a tall, stout shrub, whose smaller branches in July become covered with an exudation, which is eaten as a sweetmeat, and exported in quantity to Russia and India. The second variety, *Taranjabin,* is yielded by the camelthorn, *Alhagi Camelorum* Fisch., in Persia and Afghanistan, and probably by *Alhagi Maurorum* of De Candolle, a leguminous thorny shrub abundant in India—if indeed the two species be distinct. According to A. Villiers, it is nearly pure melezitose. (*P. J.,* 1876, 3d ser., vii, 917.) Another kind of manna is *Gazangabin,* or *Gazanjabin,* yielded by *Tamarix gallica* Linn., var. *mannifera;* a fourth kind is obtained from the *Salsola fœtida* DC. (*P. J.,* Dec. 11, 1886, 467.) The *tamarisk* of Northern Africa (*Tamarix gallica* Ehr.), which produces the small *tamarisk galls* of Mogador, containing 40 per cent. of tannic acid (*A. J. P.,* 1878, p. 27; also *N. R.,* 1877, p. 41), according to Burckhardt also gives origin to a species of manna that is used by the Bedouin Arabs near Mount Sinai with their food. This substance, however, according to Mitscherlich, contains no mannite, but consists wholly of mucilaginous sugar. Berthelot found a manna from Sinai to consist of 55 per cent. of cane sugar, 25 of levulose and glucose, and 20 of dextrin and analogous substances. (*Ann. Ch. Phys.,* lxvii.)

Persian Manna, or *Gez,* has been identified (*C. D.,* 1894, 790) as being derived from *Astragalus anisacanthus,* and is found in the districts of Khonsar, Feridan and Chahar Mahal, and Ispahan. In the form of sweetmeat, having the appearance of flour, it is sent all over Persia and much esteemed.

Australian Mannas.—A manna-like exudation on the *Eucalyptus viminalis* Labill., growing in New South Wales, contains a saccharine matter called *melitose,* different in properties from mannite and from all the varieties of sugar, though isomeric with glucose. It is susceptible of the vinous fermentation. (See *A. J. P.,* xxviii, 157.) *Lerp* is produced upon the leaves of *Eucalyptus dumosa,* when very small, and sometimes appears spread over large extents of country like a kind of snow. The natives use it for food. It is a complex body, containing an unfermentable sugar, *eucalin,* gum, starch, inulin, and lignin. (*J. P. C.,* xvi, 240.) It is said to be a secretion from an insect, formed into minute cells, each of which is the abode of one of the insects. (See *A. J. P.,* 1862, p. 547.) *Myoporum platycarpum* R. Br., the *sandalwood-* or *dogwood-tree* of Australia, exudes

an exceedingly sweet and pleasant manna, which is much used as an article of food. The product is identical with the official manna, containing nearly 90 per cent. of mannite. F. W. Passmore obtained from *Eucalyptus Gunnii* Hook., a sugar termed *melitriose.* (*P. J.*, 1891, 718.)

New South Wales Manna.—According to R. T. Baker (*Journ. and Proc. Roy. Soc. New South Wales*, xxx, 1897), this manna is produced in the form of nodules at the nodes of the stems of the blue grass *Andropogon annulatus.* It contains numerous crystals of mannite, amounting, according to the analysis of H. G. Smith, to 50 per cent.

Fraxinus Ornus, or the *European flowering ash* is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiolate, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the end. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright green color, and supported on short footstalks. The flowers are white, and usually expand with the leaves. They grow in close panicles at the extremities of the young branches, and have a very short calyx with four teeth, and four linear-lanceolate petals.

Fraxinus Ornus is native of Sicily, Calabria, and Apulia, and is cultivated in Sicily. It yields manna after the eighth year, and continues to yield it for ten or twelve years, when it is usually cut down and young sprouts are allowed to grow up from the root. (Stettner, *A. Pharm.*, liii, 194.) During the hot months the juice exudes spontaneously from the bark, and concretes upon its surface, but, as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for the whole period during which the tree yields manna, extending sometimes, it is said, to thirty or even forty years. Straw or chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies in its character according to the mode of collection, the nature of the season, and the period of the year at which the exudation takes place. That procured in Sicily is said to be the best. Daniel Hanbury travelled through the old manna region, and satisfied himself that the collection of manna for commercial purposes is confined almost exclusively to Sicily. (*P. J.*, Nov., 1872, 421.) For information on manna collection in Sicily, see notes by J. S. Ward. (*P. J.*, 1893, 381.) For an interesting description of California mannas by J. U. Lloyd, particularly *Picolo's manna*, see *A. J. P.*, 1897, 329.

In commerce three varieties are distinguishable:

1. Flake Manna, or *manna canulata* (*cannellata*), is the purest variety, and is chiefly obtained from Palmero. It exudes spontaneously, or from incisions, during the hottest and dryest weather in July and August. According to Stettner, it is furnished by the upper incisions upon the trunk, while the lower incisions yield the inferior varieties. It is in irregular, unequal pieces, often several inches long, resembling stalactites, rough, light, porous, brittle, whitish or yellowish-white, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small fragments, generally less than an inch in length.

2. Common Manna—*manna communis*, or the *manne en sorte* of French pharmacy—is next in quality, and is collected in Sicily in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. Common manna consists of whitish or yellowish fragments, similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter, identical with fat manna.

3. Fat Manna, or *Manna* (*pinguis*) *sordida*, is collected in the latter part of October and November, when the weather is cooler and rains are more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce, it is in the form of a soft, viscous mass, containing few crystalline fragments, of a brown or yellowish-brown color, and full of impurities. The U. S. Pharmacopœia directs that such manna should be rejected.

Fictitious Manna.—Attempts have been made to counterfeit manna, but the facility of detection renders such frauds unprofitable, and they are not often practised. R. P. Thomas described (*A. J. P.*, xxiv) a sophisticated manna which differed from the genuine drug both in sensible and in chemical properties, not even containing mannite. Baumé describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid, several times successively, in the manner practised by candle makers. It may be still further purified by the use of animal charcoal. Thus prepared, it contains less mannite than flake manna, and less of the nauseous principle, but is said not to operate less effectively as a laxative. A fictitious manna is described by Edmond Histed (*P. J.*, April, 1870) as having been taken from Paris to London, which bears a close resemblance to

flake manna, for which it might be mistaken upon a hasty notice. The resemblance was, moreover, increased by the fact that it contains mannite, of which Histed obtained 40 per cent., while fine natural flake manna yielded him 70 per cent. Closely examined, it is found to differ essentially from genuine flake manna, showing no crystals of mannite when broken, not having the taste and smell characteristic of good manna, and, besides, being cleaner, lighter-colored, more solid, and making a clearer solution in water. (See *A. J. P.*, 1870.) This may have been a specimen of artificial flake manna, prepared from the inferior or common manna.

Properties.—Manna is officially described as "in irregular, more or less elongated, flattened, 3-sided pieces; externally yellowish-white; friable, somewhat waxy; internally nearly white, porous and crystalline in appearance; odor slight, but characteristic; taste sweet, slightly bitter and faintly acrid. Manna also occurs in irregular masses, consisting in part of brittle or soft, resin-like fragments; from yellowish-white to yellowish-gray in color. The quantity of the yellowish-white fragments must not be less than 40 per cent. of the whole. Add 5 Gm. of Manna to 100 mils of alcohol, heat to boiling and filter; on cooling, the filtrate rapidly deposits crystals of mannite." *U. S.*

Manna has a slight, peculiar odor, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna scarcely so much so as to be disagreeable. Its sp. gr. is 0.834. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold and in its own weight of boiling water. From a boiling saturated aqueous solution it separates in partially crystalline masses on cooling. Alcohol also dissolves it. Boiling alcohol will dissolve 15 parts of manna, and upon cooling deposit beautiful crystals of mannite.

Ebert (*Zeit. Oest. Apoth. Ver.*, xlvi, p. 427) has contributed a very able paper, containing citations of all the literature up to 1908, regarding the origin and pharmacognosy of the different varieties of manna. Probably the most comprehensive monograph on the ash manna is that of Tschirch in his large work entitled "*Handbuch der Pharmakognosie.*" Band II, p. 103.

Fourcroy and Vauquelin found manna to consist of (1) a peculiar sweet principle, *mannite*, which constitutes 75 per cent.; (2) a variety of sugar; (3) a yellow nauseous matter, upon which the purgative property is thought chiefly to depend; and (4) a little mucilage. Leuchtweiss obtained from 105 parts of manna, 11.6 of water, 0.4 of insoluble matter, 9.1 of sugar, 42.6 of mannite, 40.0 of a mixture of mucilaginous matter containing mannite, resin, organic acid, and a nitrogenous substance, and 1.3 of ashes. In *manna canellata in fragmentis* he found 37.6 per cent. of mannite, and in *manna Calabrina* 32 per cent. (*Pflanzenstoffe*, 2d ed., p. 180.) Buignet discovered in manna a considerable proportion of dextrin. He appears to have been led to this discovery by observing a very energetic dextrogyrate power in flake manna, which could not be owing to the saccharine matter it contained, because the same power continued after all the sugar had been destroyed by fermentation. Dextrin forms about one-fifth part of flake manna, and a much larger part of the inferior kinds. Tanret (*Bul. Soc. Ch.*, 1902, p. 947) finds manna to contain several new carbohydrates and reports the composition as follows: mannitol, 40 to 55 per cent.; levulose, 2.5 to 3.4 per cent.; dextrose, 2.2 to 3.0 per cent.; manneotetrose ($C_{24}H_{42}O_{21} + 4H_2O$), 12 to 16 per cent.; manneotriose ($C_{18}H_{32}O_{16}$), 6 to 16 per cent., with small amounts of resin and ash.

Flückiger found in all samples of mannite examined a small amount of a dextrogyrate mucilage, which is precipitated by neutral lead acetate, and yields mucic acid when boiled with strong nitric acid. The greenish color of certain pieces of manna is produced by *fraxin*, $C_{16}H_{18}O_{10}$, a glucoside closely resembling *æsculin*. Fraxin crystallizes in colorless prisms, easily soluble in hot water and in alcohol, and has a faintly astringent and bitter taste. By diluted acids it is resolved into *fraxetin*, $C_{10}H_8O_5$, and *glucose*, $C_6H_{12}O_6$. Even its diluted solutions are fluorescent. (*Pharmacographia*, 2d ed.)

Mannite (*mannitol*) is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is $C_6H_{14}O_6$, and it is considered as belonging to the class of *hexatomic alcohols*. If mixed with chalk and cream-cheese and kept for some weeks at the temperature of 40° C. (104° F.), it yields alcohol largely, with the disengagement of carbonic acid and hydrogen and the production of lactic acid. No fungus is produced, as in the ordinary fermentation of sugar. (Berthelot, *J. P. C.*, xxx.) With lime, barium and strontium oxides, it forms definite compounds, soluble in water, and precipitable from their aqueous solutions by alcohol. (*Ibid.*, Jan., 1860.) It does not reduce an alkaline solution of copper oxide; and a test of its purity is thus presented. (*A. J. P.*, Jan., 1861, p. 26.) It is optically inactive except after the addition of borax. It is then found to be dextrorotatory. Emil Fischer has shown that there are three mannites obtainable; the ordinary mannite is the dextrorotatory variety, and is always obtained in the reduction of *a*-mannose with sodium amalgam; a lævorotatory variety is obtained by the reduction of *l*-mannose; and an inactive mannite is obtained from the inactive mannose. These three physical isomers differ slightly in their fusing points and crystalline form. The native variety may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate; pure mannite is now deposited. An-

other method is to dissolve flake manna in water, precipitate by solution of lead subacetate, filter, throw down the excess of lead by sulphuric acid, evaporate the solution, and mix with alcohol. On cooling, the mannite is deposited. (Bonsall, *A. Pharm.*, cxxxiv, 70.) This principle has been found in numerous vegetables. It is said to be gently laxative in the dose of from one to two ounces (31–62 Gm.).

Manna, when long kept, acquires a deeper color, softens, and ultimately deliquesces into a liquid, which on the addition of yeast, undergoes the vinous fermentation. This is probably owing to its conversion into sugar by the absorption of enough oxygen to cause it to pass over into some variety of glucose or fermentable sugar. That which is driest resists this change the longest. It is said that manna recently gathered is less purgative than it afterwards becomes.

Uses.—Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. It is usually prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect. It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be administered in substance. Manna forms a combination with iron, which it preserves against oxidation. (See *P. J.*, March, 1873.) Under the name of *dulcinol* a mixture of mannite and common salt has been recommended by Sternberg (*D. M. W.*, 1906, p. 1707) as a sweetening agent in *diabetes*.

Dose, half to one ounce (15.5–31 Gm.).

MASSA FERRI CARBONATIS. U. S.

MASS OF FERROUS CARBONATE Mass. Ferr. Carb.
[Vallet's Mass]

(măs'sa fĕr'rī cär-bo-nā'tĭs)

"It contains not less than 35 per cent. of $FeCO_3$ (115.84)." *U. S.*

Pilula Ferri Carbonatis, *Br.* 1885, also *U. S.* 1870; Pilulæ Ferri Carbonici, Pilulæ Ferratæ Valleti; Pill of Carbonate of Iron, Vallet's Ferruginous Pills, Vallet's Pill Mass; Pilules de Carbonate ferreux, *Fr. Cod.*; Pilules ferrugineuses, Masse Pilulaire de Vallet, *Fr.*; Valletsche Pillen, *G.*; Pillole di Vallet, *It.*

* "Ferrous Sulphate, *one hundred grammes* [or 3 ounces av., 231 grains]; Monohydrated Sodium Carbonate, *forty-six grammes* [or 1 ounce av., 272 grains]; Clarified Honey, *thirty-eight grammes* [or 1 ounce av., 150 grains]; Sugar, in coarse powder, *twenty-five grammes* [or 386 grains]; Syrup, Distilled Water, each, *a sufficient quantity*, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the ferrous sulphate and the monohydrated sodium carbonate, each separately, in *two hundred mils* [or 6 fluidounces, 366 minims] of boiling distilled water, and, having added *twenty mils* [or 325 minims] of syrup to the solution of the iron salt, filter both solutions, and allow them to become cold. Place the solution of monohydrated sodium carbonate in a bottle having a capacity of about *five hundred mils* [or 16 fluidounces, 435 minims], and gradually add the solution of the iron salt, rotating the bottle frequently, until carbonic acid gas no longer escapes. Add sufficient distilled water to fill the bottle; then cork it and set it aside, so that the ferrous carbonate may subside. Pour off the supernatant liquid, and, having mixed syrup and distilled water in the proportion of *one volume* of syrup to *nineteen volumes* of distilled water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the water as possible. Lastly, mix the precipitate at once with the clarified honey and sugar, and, by means of a water-bath, evaporate the mixture in a tared dish, with constant stirring, until it is reduced to *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

"**Assay.**—Dissolve about 1 Gm. of Mass of Ferrous Carbonate, accurately weighed, in 15 mils of diluted sulphuric acid, dilute the solution with distilled water to about 100 mils and immediately titrate with tenth-normal potassium dichromate V.S., potassium ferricyanide T.S. being used as indicator. It shows not less than 35 per cent. of $FeCO_3$.

"Each mil of tenth-normal potassium dichromate V.S. used corresponds to 0.011584 Gm. of $FeCO_3$. Each gramme of Mass of Ferrous Carbonate corresponds to not less than 30.2 mils of tenth-normal potassium dichromate V.S." *U. S.*

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharatus* and *Syrupus Ferri Iodidi*. The U. S. mass of ferrous carbonate is another example of a ferruginous preparation in which the iron is protected from further oxidation by the same means. The process of the U. S. P. IX is nearly the same as that of the U. S. P., 1890, excepting that the monohydrated sodium carbonate has replaced the crystallized variety, and the quantity of the alkaline salt has been somewhat increased. The salts employed are the same as those used for obtaining the formerly official ferric subcarbonate which was misnamed, as in forming that preparation the carbonate which is at first precipitated absorbs oxygen, and loses nearly all its carbon dioxide in the processes of washing and drying. When, however, as in the U. S. formula above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with weak syrup also, the absorption of oxygen and loss of carbon dioxide during the separation of the precipitate are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water bath. It is essential to the success

of this process that the ferrous sulphate should be pure, otherwise some ferric oxide will be present in the product. The process is that of Vallet, of Paris, after whom the preparation is popularly called.

The British Pharmacopœia, 1898, omitted Vallet's mass. (See *Ferri Carbonas Saccharatus.*) Gonnermann prepares *powdered Vallet's mass* by mixing intimately ten parts of milk sugar and five parts of powdered licorice root with sufficient freshly precipitated ferrous carbonate to make, when dried, thirty-five parts, and adding enough powdered licorice root to make the whole weigh forty parts. (*Ph. Post,* 1893, 238.)

Properties.—The U. S. preparation is in the form of a soft pilular mass, of a dark greenish-gray color, becoming black on exposure, and with a strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of ferrous carbonate. The corresponding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Uses.—The U. S. mass of ferrous carbonate, or Vallet's ferruginous mass, is an excellent preparation for use in simple *anemia* and *chlorosis.* Its chief merits are its unchangeableness, its freedom from astringency, and its ready solubility in acids.

Dose, in pills, from three to five grains (0.20–0.32 Gm.), after meals.

MASSA HYDRARGYRI. U. S. (Br.)

MASS OF MERCURY Mass. Hydrarg. [Blue Mass Blue Pill]

(măs'sa hȳ-drär'gȳ-rī)

"It contains not less than 32 per cent. nor more than 34 per cent. of Hg. Preserve the product in well-closed containers." *U. S.*

Pilula Hydrargyri, *Br.,* Mercury Pill; Pilulæ Hydrargyri, *U. S.* 1870; Pilulæ Cœruleæ, Massa Cœrulea; Pills of Mercury; Mercurial Pill; Pilules mercurielles simples, *Fr. Cod.;* Pilule de Mercure, Pilules bleues, *Fr.;* Mercurialpillenmasse, *G.*

* "Mercury, *thirty-three grammes* [or 1 ounce av., 72 grains]; Oleate of Mercury, *one gramme* [or 15 grains]; Glycyrrhiza, in No. 60 powder, *ten grammes* [or 154 grains]; Althæa, in No. 60 powder, *fifteen grammes* [or 231 grains]; Glycerin, *nine grammes* [or 139 grains]; Honey of Rose, *thirty-two grammes* [or 1 ounce av., 56 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the oleate of mercury in a warm mortar, gradually add the mercury, then introduce a small amount of honey of rose and triturate the mixture until globules of mercury are no longer visible under a lens magnifying ten diameters. Now incorporate the remainder of the honey of rose and the glycerin, then gradually add the glycyrrhiza and althæa and continue the trituration until the mass is homogeneous." *U. S.*

"Mercury, 40 *grammes;* Confection of Roses, 60 *grammes;* Liquorice Root, in powder, 20 *grammes.* Triturate the Mercury with the Confection of Roses until metallic globules are no longer visible; add the Liquorice Root; mix to form a mass." *Br.*

"**Assay.**—Place about 0.5 Gm. of Mass of Mercury, accurately weighed, in a porcelain dish, add 10 mils of sulphuric acid, heat on a water bath for ten minutes, then add 10 mils of nitric acid and heat the mixture on a sand bath, adding small portions of nitric acid, if necessary, until a colorless or nearly colorless solution results. Now add potassium permanganate T.S. to the hot solution until the red color persists, then discharge the color by the addition of just sufficient oxalic acid T.S. Wash the solution into a flask with distilled water, dissolve any insoluble residue by the addition of nitric acid, dilute the solution to about 150 mils, add 2 mils of ferric ammonium sulphate T.S. and titrate the solution with tenth-normal potassium sulphocyanate V.S. to the production of a pink tint. It shows not less than 32 per cent. nor more than 34 per cent. of Hg.

"Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.01003 Gm. of Hg. Each gramme of Mass of Mercury corresponds to not less than 31.9 nor more than 33.9 mils of tenth-normal potassium sulphocyanate V.S." *U. S.*

The mercury constitutes one-third of the mass. The U. S. process is well suited for the needs of the pharmacist, as the mass can be made with ordinary apparatus extemporaneously. The proportion of glycerin, in the formula which was increased in the U. S. VIII overcomes the tendency to harden slowly and become unfitted for use which was characteristic of the U. S., 1890, preparation.

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater proportion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into mercurous oxide, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury is not oxidized during the trituration, there can be little doubt that it becomes so, to a slight extent, by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way, and mercurous oxide is asserted to have been actually extracted from old mercurial pill. Harold Senier analyzed a number of samples of blue mass, with the view of determining the amount of metallic mercury and of mercurous and mercuric oxides. The results showed that the latter gradually increased in quantity with the age of the blue mass, which, 18 hours after preparation, con-

tained but a trace of mercurous oxide; after three months, 0.24 per cent. of mercuric and 0.62 per cent. of mercurous oxides were obtained, and in another sample, 0.44 and 1.60 per cent., respectively. After two years, 1.80 per cent. of mercuric and 4.22 per cent. of mercurous oxides were present. (*P. J.*, 1876.) Nevertheless, it scarcely admits of dispute that the metal, independently of oxidation out of the body, is capable of producing the peculiar mercurial effects when introduced into the stomach, probably undergoing chemical changes there. The U. S. VIII provided a test which limited the quantity of mercurous oxide and proved the absence of mercuric oxide; it will be difficult for the ordinary "blue mass" of commerce to withstand these requirements: "If a portion of the Mass be triturated in a mortar, with warm acetic acid, the filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of *mercurous oxide*). If another portion of the Mass be digested with warm, diluted hydrochloric acid and a little purified animal charcoal, the filtrate should not be affected by hydrogen sulphide T.S., or by stannous chloride T.S. (absence of *mercuric oxide*)." *U. S. VIII.* All agree that the efficacy of the preparation is proportionate to the extinguishment of the mercury; in other words, to the degree in which the metallic globules disappear. This may be effected by trituration with various substances, and manna, syrup, honey, licorice, mucilage, soap, guaiac, and extract of taraxacum have been recommended, among others, for this purpose; but the oleate of mercury has been adopted by the U. S. P. IX as less open to objection than any other. The mercury is known to be completely extinguished when, upon rubbing a portion of the mass with the end of the finger upon a piece of paper, no globules appear, or the extinguishment may be more accurately judged by the official microscopic test. Powdered licorice root and powdered marshmallow root are added in order to give due consistence to the mass. It is possible for the apothecary to make moderate quantities extemporaneously with no other appliances than the mortar and pestle. As the trituration requires to be long continued, which renders the process very laborious when conducted on the large scale, it is customary to prepare the mass by machinery. A machine which has been employed consisted of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axes." A machine for preparing blue mass, capable of being worked by hand or steam power, was invented by J. W. W. Gordon, of Baltimore, and, having been found to answer well, was at one time in extensive use. (*A. J. P.*, xxi, 6.) We have referred, under *Hydrargyrum cum Creta* (page 569) to another ingenious apparatus, invented by Squibb, by which the extinguishment of mercury is very satisfactorily effected. Formerly much of the blue mass used in this country was imported, but at present the market is chiefly supplied by our own manufacturers. The preparation slowly changes color upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.

In consideration of the incomplete extinguishment of the mercury in many specimens of the blue pill, arising from the tedious process employed, F. B. Benger proposed to obtain the metal in a state of minute division by reduction of mercuric chloride solution by means of stannous chloride. An obvious objection to the process is the possibility, with carelessness of manipulation, of having in the preparation a minute proportion of corrosive sublimate or stannous chloride.

The blue pill is sometimes wanted in the state of powder, but, from its peculiar constitution, it is not eligible for reduction to this form, as the mercury is disposed to aggregate during pulverization, and, from the honey it contains, it is likely, when pulverized, to attract moisture from the air. Chas. Bullock recommended the following method of preparing a powder which, as nearly as possible, represents the blue pill, in reference to its therapeutic effects:

Powdered Blue Mass.—Take of finely powdered Elm bark, finely powdered Sugar, and Mercury, equal parts, and of Alcohol a sufficiency. Rub the mercury with the powdered bark, adding from time to time enough alcohol to maintain a pasty consistence, until the mercury is completely extinguished; then spread the mass on paper to dry. When dry, powder it, add the sugar, and rub the mixture thoroughly until the powder will pass through a sieve of fine bolting cloth. (*A. J. P.*, 1859, p. 271.)

Uses.—Blue mass has the therapeutic properties of the mercurials (see *Hydrargyrum*), but is to-day chiefly employed for its cathartic action. It seems to be somewhat less irritant than calomel and the purgation caused is less frequently accompanied with griping. When used as a cathartic it is sometimes necessary to follow it after some hours with a saline.

Dose, as an alterative, one to three grains (0.065–0.2 Gm.), as a laxative, from five to fifteen grains (0.32–1.0 Gm.).

MATRICARIA. U. S.

MATRICARIA Matricar. [German Chamomile Wild Chamomile]

(măt-rĭ-cā'rĭ-ă)

"The dried flower-heads of *Matricaria Chamomilla* Linné (Fam. *Compositæ*), without the presence or admixture of more than 5 per

cent. of stems or foreign matter. Preserve it in tightly-closed containers and guard against attack by insects." *U. S.*

Flores Chamomillæ Vulgaris; Horse Gowan, Dog's Camovyne; Camomille commune (d'Allemagne), *Fr. Cod.*; Flores Chamomillæ, *P. G.*; Kamillen, Kamillenblumen, *G.*; Camomilla comune, *It.*; Manzanilla (Flor de), *Sp.*

Matricaria Chamomilla is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves, the lower being tripinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and very small. The flower-heads appear singly at the ends of the stem and branches. The bracts of the involucre are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray-florets are pistillate white, at first spreading, and ultimately reflected. The disk is of a deep yellow color, at first flat, but in the end convex, and in some cases somewhat conical. The plant is a native of Europe and western Asia, and is occasionally cultivated in our gardens. It is also naturalized in North America and Australia. Mitlacher gives the results of methods of cultivating matricaria in *Zeit. Oest. Apoth. Ver.*, l, p. 410. Meyer has suggested (*Pharm. Zeit.*, lviii, p. 790) the practicability of scientifically collecting matricaria from the wild grown plants. All parts of it are active, but the flowers only are official. These are gathered from May to August, shrink in drying, so that they are scarcely half as large as in their recent state. Those found in commerce are imported from Germany.

Properties.—Matricaria is officially described as follows: "Flower-heads composed of a few white ray-florets and numerous yellow disk-florets on conical, more or less hollow receptacles, the latter being from 3 to 10 mm. in breadth; disk-flowers tubular, perfect, and without a pappus; ray-flowers from 10 to 20, pistillate, corolla white, 3-toothed and 4-veined, usually reflexed; involucre hemispherical, composed of from 20 to 30 imbricated, oblanceolate, and pubescent scales; peduncles light green to brownish-green, longitudinally furrowed, more or less twisted and attaining a length of 2.5 cm.; achenes somewhat obovoid and faintly 3- to 5-ribbed; pappus none, or only a slight membranous crown; odor pleasant, aromatic; taste aromatic and bitter. Matricaria yields not more than 13 per cent. of ash." *U. S.*

"The similar flower-heads of *Anthemis arvensis* L., and *Maruta Cotula* De Candolle (Fam. *Compositæ*), have conical, solid, and chaffy receptacles." *U. S. VIII.*

In addition to the above it is sometimes admixed with the flower-heads of other European species of *Anthemis*. Sometimes the flower-heads of the common daisy (*Chrysanthemum Leucanthemum* L.) as well as other species of *Chrysanthemum* are present in the drug of commerce.

The dried flowers of matricaria are considerably smaller than those of common chamomile, and exhibit a larger proportion of the disk-florets compared with those of the ray. They have a strong, peculiar, rather unpleasant odor, and a disagreeable, bitter taste. Their active constituents are volatile oil and bitter extractive, which are readily taken up by water and alcohol. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, and of a fine deep blue color becoming green and brown by age, and almost opaque in mass. Though supposed by Gerhardt to be identical with the oil of chamomile (*Anthemis nobilis*), it has been shown to be distinct. (*P. J.*, Feb., 1862, p. 429.) It congeals at −20° C. (−4° F.), has the sp. gr. 0.93, and contains a terpene, $C_{10}H_{16}$, and a colorless oil, $C_{10}H_{16}O$. *Schimmel & Co.'s Report* for April, 1897, states that the German chamomile oil contains a paraffin hydrocarbon, which was obtained as a snowy white solid melting at 53° to 54° C. (127.4°–129.2° F.). The blue color is due to a volatile principle called *azulene* by Piesse, and *cærulein* by Gladstone and others; also found in oil of absinthe, yarrow and some other blue volatile oils. This, when distilled with potassium, yields a terpene, $(C_{10}H_{16})_3$, and with phosphoric oxide a hydrocarbon, $C_{10}H_{14}$. (Kachler, *Ber. d. Chem. Ges.*, iv, 36.)

Uses.—Matricaria is a mild tonic, very similar to chamomile in medicinal properties, and, like it, in very large doses an emetic. It is considered also in Europe to be antispasmodic and anthelmintic. It is much employed in Germany, but in this country scarcely at all, unless by German practitioners. It may be given for the same purposes and in the same manner as chamomile.

Dose, half an ounce (15.5 Gm.).

Off. Prep.—Species Emollientes, *N. F.*

MEL. U. S.

HONEY

(mĕl)

"A saccharine secretion deposited in the honey-comb by the bee, *Apis mellifera* Linné (Fam. *Apidæ*)." *U. S.*

Miel, *Fr. Cod.*; Mel, *P. G.*; Honig, *G.*; Miele, *It.*; Miel, *Sp.*

From the nectaries of various flowers the bee and other insects extract a thin, aqueous fluid, nearly without flavor and insipidly sweet, usually known as *nectar*. As honey is made out of this substance it is very much affected by the character of the nectar, so that the nature of the plants which predominate in the vicinity of the hive is a matter of great importance to the bee culturist, not only in regard to the flavor of the honey which is yielded, but even to its freedom from poisonous qualities, cases having been reported from time to time of poisoning produced by the eating of honey which had not been tampered with after extraction from the hive. In the United States honey made by the

bee from the flowers of the Mountain Laurel (*Kalmia*) is especially poisonous. See *N. J. M. R.*, 1852, 46; "*Poisonous Honey*," by L. F. Kebler, *Proc. A. Ph. A.*, 1896, 167; H. Bley, *Ph. Ztg.*, Nov., 1885. The latter states that *Datura Stramonium* and *Gelsemium* are for honey making especially dangerous plants. The nectar when taken in by the bee is chemically changed by secretions from glands in the head and thorax, levulose, dextrose, and rarely sucrose being formed. The finest honey is that which is allowed to drain from the comb. If obtained from hives that have never swarmed, it is called *virgin honey*. An inferior kind is procured by submitting the comb to pressure, and if heat be employed previous to expression, the product is still more impure. The honey which is most highly esteemed is that made from the nectar of the white clover blossom. Equally valuable is the honey derived from raspberry blossoms and bass-wood flowers. The honey made late in the summer from the flowers of the buckwheat is darker in color. The largest producer of honey in the United States is California. The United States is said to be the greatest honey producing region on the globe, the annual production being between 60,000,000 and 75,000,000 pounds annually. Nearly 2,000,000 pounds of wax are also produced in this country.

Propolis is a resinous substance, deposited by bees at the base of the hive, and in other parts which require protection from the outer air, of a nature entirely different from that of wax or honey, and supposed to be intended for the protection of the comb from injurious agencies. H. O. Hitchcock (*Chicago Med. Journ.*, 1867) considers it one of the best remedies in *diarrhea* and *dysentery*. It is of a dark reddish or yellowish-brown color, of a shining fracture, an aromatic taste and odor, quite insoluble in water, nearly so in ether, but readily dissolved by alcohol and solution of potassium hydroxide. Hitchcock used a tincture (two drachms of propolis and four fluidounces of alcohol) in doses of from thirty minims to a fluidrachm (1.8–3.75 mils).

Bee bread is the name given to a material found in some of the cells of the comb, consisting mainly of the pollen of plants. (*Chicago Med. Examiner*, Sept., 1865.) Jas. S. Whitmire found that in the dose of a drachm (3.9 Gm.) three times a day it caused great increase of the urinary secretion. No disagreeable affects followed its use, except a slight flatulency and looseness of the bowels. It is entirely palatable and inoffensive to the stomach. (*A. J. P.*, 1866.)

Eucalyptus Honey, or *Black Honey*.—This honey, a detailed description of which may be found in *U. S. D.*, 16th ed., appears to have been not a natural but a sophisticated article.

In the recent state honey is fluid, but on being kept it is apt to form a crystalline deposit, and to be ultimately converted into a soft granular mass. In commerce it is found of every consistence, from that of a viscid liquid, like thin syrup or oil, to that of lard or soft suet. Its color is sometimes white, but usually yellowish, and occasionally of a brownish or reddish tinge. It has a peculiar agreeable odor, varying somewhat with the flowers from which it was collected, and a very sweet, feebly aromatic taste, which is followed by a slight prickling or sense of acridity in the fauces. Cold water dissolves it readily, alcohol with less facility. "Honey is a thick, syrupy liquid of a light yellowish or yellowish-brown color, translucent when fresh, but gradually becoming opaque and crystalline; having a characteristic odor, and a sweet, faintly acrid taste. It is slightly acid to litmus and is lævorotatory. Dilute Honey with twice its weight of water; the resulting liquid is only moderately turbid, not stringy, and has a specific gravity of not less than 1.099 at 25° C. (77° F.) (corresponding to a specific gravity of not less than 1.370 for the original Honey). Incinerate about 1 Gm. of Honey, accurately weighed, in a platinum crucible, in small portions at a time; not more than 0.3 per cent. of ash remains. Separate portions of 5 mils each of a filtered aqueous solution of Honey (1 in 5) acidified with nitric acid, are not rendered more than slightly opalescent by the addition of a few drops of silver nitrate T.S. (*chlorides*), nor more than slightly cloudy by a few drops of barium chloride T.S. (*sulphates*). Boil about 2 Gm. of Honey with 10 mils of distilled water; the resulting solution, when cold, is not rendered blue, green or reddish on the addition of iodine T.S. (*starch or dextrins*). The color of an aqueous solution of Honey (1 in 2) is not changed at once when mixed with an equal volume of ammonia water (*foreign coloring matter*); 5 mils of an aqueous solution of Honey (1 in 2) does not at once acquire a red or rose color on the addition of a few drops of hydrochloric acid (*azo dyes*). A solution of 10 Gm. of Honey in 50 mils of distilled water requires not more than 0.5 mil of normal potassium hydroxide V.S. for neutralization, phenolphthalein T.S. being used as indicator. Triturate about 1 Gm. of Honey with 20 mils of ether in a mortar, filter it into a porcelain dish or crucible, allow the filtrate to evaporate and add to the residue one drop of resorcinol T.S. At most only a pink color may be produced, which disappears in half a minute, but not an orange, cherry, or brown-red color (*artificial or added invert sugar*)." *U. S.*

It is essentially a strong aqueous solution of mixed dextrose and levulose, amounting generally to from 70 to 80 per cent. According to Wm. A. Selser, who separated wax from honey on a large scale, the proportion of wax in the honey comb averages 1 per cent.; from 1500 pounds he obtained 14¼ pounds of wax by actual experiment. (*A. J. P.*, 1904, 267.)

A large number of samples of genuine honey analyzed in 1897 for the Department of Inland Revenue, Canada (Bull. 47), showed the following variations:

Direct polarization, −2.4 to −19.
Invert polarization, −10.2 to −28.
Sucrose (by Clerget), 0.5 to 7.64 per cent.
Invert sugar, 60.37 to 78.8 per cent.
Water, 12 to 33 per cent.
Ash, 0.03 to 0.50 per cent.

Neufeld in *Der Nahrungsmittelchemiker als Sachsverständiger*, Berlin, 1907, p. 275, gives the following limits for pure honey of European origin:

Water	8.30	to 33.59	per cent.
Protein	0.03	to 2.67	per cent.
Invert sugar	49.59	to 93.96	per cent.
Sucrose	0.10	to 10.12	per cent.
Dextrin	0.99	to 9.70	per cent.
Formic acid	0.03	to 0.21	per cent.
Ash	0.02	to 0.68	per cent.

Browne has published a comprehensive article on American honey (*U. S. Dept. Agric., Bur. of Chem., Bull.* 110, 1908) of which the tabular analyses are given in Leach, *Food Inspection and Analysis*, 3d ed., p. 635.

The *honey sugar* may be obtained by treating granular honey with a small quantity of alcohol, which, when expressed, takes along with it the other ingredients, leaving the crystals nearly untouched. The same object may be attained by melting the honey, saturating its acid with calcium carbonate, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a large proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation. In warm weather, honey, itself, if not very pure, sometimes ferments, acquiring a pungent taste and deeper color. The presence of dextrin in pure honey seems to be established. G. L. Spencer (*A. J. P.*, 1895, 27) has found as much as 4 per cent. of dextrin, and Haenle (*Zeit. An. Chem.*, xciv, 99) has found that honey from *Coniferæ* always contains dextrin. Künnmann and Hilger (*A. J. P.*, 1896, 570) state that dextrin is present in all honey, whether dextrorotatory or lævo-rotatory, and claim to have identified it as achroo-dextrin. Müllenhoff believes that the honey is preserved in the sealed cells of the comb by the secretion with it of a minute quantity of formic acid, and has found by experiment that the addition of one part of 25 per cent. formic acid is sufficient to keep permanently 250 parts of honey, but in this connection it should be remembered that the absence of contact with the air would account for the preservation of honey in the comb. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration may be detected by adding water, which dissolves the honey and leaves the starch at the bottom of the vessel. Dilution with water may be suspected from the greater thinness of the honey and its want of disposition to crystallize.

Honey is sometimes adulterated with artificial glucose. This cannot be detected by the official tests with certainty, but the safest method is to employ the polariscope. (See Leach, "*Food Adulteration and Analysis.*")

According to Oscar Haenle, glucose can also be detected by first dialyzing thoroughly and then polarizing, under which circumstance, if glucose be present, rotation to the right occurs; if the honey be pure the light is not affected. Undialyzed honey ordinarily polarizes to the left, but unadulterated conifer honeys are dextrogyrate. (*P. J.*, xxi.)

Honey has been frequently adulterated with artificial invert sugar. This is best detected by the official method given above.

Uses.—Honey possesses the same medicinal properties as sugar, but is more disposed to affect the bowels. Though largely consumed as an article of food, it is seldom employed medicinally, except as a vehicle. Its taste and demulcent qualities render it a useful addition to gargles, and it is sometimes employed as an application to *foul ulcers*.

MEL BORACIS. Br.

BORAX HONEY

(mĕl bo-rā′cĭs)

Mel Sodii Boratis, *U. S.* 1870; Honey of Borax, Honey of Borate of Sodium; Miel boraté, Mellite de Borax, *Fr.*; Boraxhonig, *G.*

"Purified Borax, in powder, 10 *grammes;* Glycerin, 5 *grammes;* Purified Honey, 85 *grammes.* Mix." *Br.*

This preparation was very properly dropped from the U. S. Pharmacopœia at the 1880 revision, but is recognized by the N. F. IV, the formula being identical with the British process given above. Borax honey is used in the *thrush* of infants and in *aphthous ulcerations* of the mouth.

MEL DEPURATUM. U. S., Br.

CLARIFIED HONEY Mel Depurat. [Mel Despumatum, U. S. 1890]

(mĕl dĕp-ū-rā′tŭm)

"Purified Honey is honey of commerce melted and strained, the specific gravity, if necessary, being adjusted to 1.36 by the addition of Distilled Water." *Br.*

Purified Honey; Mellite simple, *Fr. Cod.*; Miel déspumé, *Fr.*; Mel depuratum, *P. G.*; Gereinigter Honig, *G.*; Miele depurato, *It.*; Miel depurada, *Sp.*

* "Honey, *a convenient quantity,* Distilled Water, Glycerin, each, *a sufficient quantity.* Weigh the honey in a tared dish, mix it intimately with *two per cent.* of paper pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water, and then strongly expressed and again shredded. Then heat on a water bath at a temperature not exceeding 70° C. (158° F.), and carefully remove the scum which rises to the surface. Add

enough distilled water to make up the loss incurred by evaporation, strain, and mix the strained liquid with *five per cent.* of its weight of glycerin." *U. S.*

The U. S. method of clarifying honey was new as far as the Pharmacopœia was concerned in 1890. Paper-pulp is very effective as a clarifying agent, and the glycerin offers some protection to the honey against change. Honey may be made brilliant by hot filtration through paper. (See Remington's *Practice of Pharmacy*, "Hot Filtration."

Honey, by the heat of the water bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface and may be skimmed off, while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom. It is officially required that "Clarified Honey, diluted with twice its weight of water, has a specific gravity of not less than 1.095 at 25° C. (77° F.); in other respects it conforms to the tests for purity under *Mel.*" *U. S.*

A neat method of separating is described in *N. R.*, Feb., 1880. It is as follows: "Pour the honey into a perfectly clean cylindrical vessel, with straight sides, rather narrow, and having a small lip at the open margin, and heat the vessel on a water-bath. When the water is hot, pour enough honey into the vessel to fill it to within about 1 inch of the edge, and allow it to remain at rest in the water-bath, at a moderate heat, for about one hour. During this time, most of the impurities will rise to the top, while some others may sink to the bottom. Now remove the vessel very carefully from the water-bath, and pour on top of the hot honey, very gently, a sufficient amount of cold water to fill the vessel completely. This will cause all the impurities floating on the honey to rise at once to the top of the cold water, where they will often solidify to a tough skin or cake, which may be taken off without difficulty. Then pour off the water through the lip, remove the last remnants, if necessary, by means of blotting paper, and filter the honey through a piece of well-washed, wetted, and dense white flannel. The resulting product—if the honey be pure—will be very brilliant." The French Codex directs one part of honey to be diluted with one part of distilled water. The specific gravity of this solution should be not less than 1.300.

(For other processes of purifying honey, see 14th edition of this work, p. 1321, also 19th ed., p. 775, and *A. J. P.*, 1877, p. 19; also 1879, pp. 193, 598; and 1880, p. 132.) Heugel's method is to mix two pounds each of honey and water with a half-ounce of magnesium carbonate, frequently agitate for two or three hours, filter through doubled white filtering paper, boil slowly, remove the scum carefully, and evaporate upon a steam bath to a syrupy consistence. Dieterich recommends the following process: Mix the honey with sufficient water (the amount depending on the consistence), heat for about seven hours on a water bath, and clarify it with 5 per cent. of its weight of powdered talc, neutralize, if necessary, with magnesium carbonate; allow to deposit, filter, add a few drops of acetic acid, and evaporate to the proper specific gravity. (*Ph. Ztg.*, 93, 712.)

The British Pharm. describes it as "a syrupy, translucent, pale yellowish liquid. Aromatic odor; taste at first sweet, afterwards faintly acrid. Specific gravity 1.36. *Optical rotation* at 15.5° C. (60° F.) of a solution in *water*, containing 25 grammes in 100 millilitres, decolorised by filtration with *animal charcoal*, in a tube 200 millimetres long, between 0° and –5° C. (32° and 23° F.); 5 millilitres of the same solution when mixed with 15 millilitres of *absolute alcohol* do not become more than faintly opalescent (absence of starch sugar). When 2 grammes are dissolved in 20 millilitres of boiling *water* and cooled, the solution does not become blue on the addition of one drop of *N/10 solution of iodine* (absence of starch). Ash not more than 0.25 per cent.; solution of the ash in *water* is not alkaline to *litmus*, and when acidified with *nitric acid* yields not more than a very faint opalescence with *solution of barium chloride*, or with *solution of silver nitrate* (limit of sulphates and of chlorides)." *Br.*

Honey clarified with calcium carbonate and animal charcoal, or as in the first process described, is as clear and colorless as syrup made with sugar, but still retains a peculiar flavor. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Dose, one to four fluidrachms (3.75–15 mils).

Off. Prep.—Confectio Piperis, *Br.;* Mel Boracis, *Br.;* Mel Rosæ, *U. S.;* Oxymel, *Br.;* Confectio Rosæ, *N. F.;* Mel Sodii Boratis, *N. F.*

MEL ROSÆ. U. S.

HONEY OF ROSE

(mĕl rō'şæ)

Mellitum Rosatum; Mellite de Rose rouge, *Fr. Cod.;* Miel Rosat, *Fr.;* Mel Rosatum, *P. G.;* Rosenhonig, *G.;* Miele rosato, *It.;* Miel de rosas, *Sp.*

* "Fluidextract of Rose, *one hundred and twenty mils* [or 4 fluidounces, 28 minims]; Clarified Honey, *a sufficient quantity* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the fluidextract of rose in a tared vessel with enough clarified honey to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

Though one of the official preparations in the London and Edinburgh Pharmacopœias, the Honey of Rose has been dropped in the British. The U. S. formula is based on that of Grahame. (See *A. J. P.*, 1859, p. 443.) As is well known, honey of rose deposits honey sugar upon standing even but a short time. Touflet (*Ph. Centralh.*, xxxvi, 307) obviates this precipitation in the following manner: Take of Powdered Rose Leaves, 25 parts; Alcohol, sp. gr. 0.875, 75 parts; Honey, 80 parts; Sugar, 34 parts. Per-

colate the rose leaves with the alcohol, filter and distil off the filtrate to 40 parts. To this add the honey and sugar, and bring to the boiling point. Honey of rose forms a pleasant addition to the gargles employed in *inflammation* and *ulceration* of the *mouth* and *throat*.

Dose, one fluidrachm (3.75 mils).

MENTHA PIPERITA. U. S.

PEPPERMINT Menth. Pip.

(mĕn'thą pĭp-ę-rī'tą)

"The dried leaves and flowering tops of *Mentha piperita* Linné (Fam. *Labiatæ*)." *U. S.*

Brandy Mint; Menthe poivrée, *Fr. Cod.*; Folia Menthæ Piperitæ, *P. G.*; Pfefferminzblätter, Pfeffermünze, *G.*; Menta piperita, *It.*, *Sp.*

The genus *Mentha* comprises at least fifteen species, of which there are also a great many varieties. Some of the mints have been in use for culinary and medicinal purposes since antiquity, but no well defined distinction is made as to just what plants were employed. It is stated that *M. piperita* L. (1753), also Smith (1800)—the most important member of this genus, was long ago cultivated by the Egyptians. It is mentioned in the Icelandic Pharmacopœia of the thirteenth century. Peppermint is now grown in considerable amounts in Europe, North America, and Eastern Asia. It is also found growing wild in other parts of the world, as South America and Australia. The oldest existing peppermint district is in the neighborhood of Mitcham (Surrey), England. In some parts of the United States, especially in Michigan, the western part of New York, Ohio and Indiana, it is largely cultivated. On the continent of Europe other species of *Mentha* (particularly *M. arvensis*) grow with *M. piperita*, deteriorating the product. In America other plants (as *Erigeron canadensis* and *Erechthites hieracifolia*) cause the same trouble. Besides *M. piperita* other species are cultivated, as some Asiatic varieties of *M. arvensis*, *M. spicata*, *M. longifolia* (var. *undulata*), *M. gentilis*, *M. dalmatica*, and *M. Pulegium*. Miss Henkel reviews the situation regarding the cultivation of peppermint in the United States and describes the three kinds of mint grown for the production of peppermint oil: *Mentha piperita* L.; *Mentha piperita vulgaris* Sole, and *Mentha piperita officinalis* Sole. (*Bul. Bur. Plant Ind., U. S. Dept. Agric.*, No. 90, 1906.) A comprehensive article on the cultivation of peppermint in Japan is that by Inouyé in *Schim. Rep.*, November, 1908, p. 199. Peppermint has recently been successfully grown in Wisconsin. (*Paint, Oil and Drug Rev.*, xliv, p. 18.) The cultivation of peppermint is a growing industry on the reclaimed lands of Louisiana. (*Spatula*, xvii, p. 18.) Great interest recently has been taken in the cultivation of peppermint in Germany. (See Thoms in *B. P. G.*, xx, p. 244; *Arb. Pharm. Inst. Univ. Berl.*, viii, p. 93.) Mitlacher reports on the cultivation of peppermint in Austria and outlines methods for its culture on a large scale. (*Ph. Post*, xliv, p. 215; *Zeit. Oest. Apoth. Ver.*, 1, p. 422.) It has been repeatedly pointed out that the essential oil-bearing plants of the *Labiatæ* are very capricious and constantly changing character with change of soil and climate. For an account of the cultivation of peppermint in Russia, see *Proc. A. Ph. A.*, 1902, 831.

Peppermint is a perennial herbaceous plant, producing creeping stolons. The stems are quadrangular, channelled, purplish, somewhat hairy and branching towards the top. The leaves are opposite, petiolate, ovate, sharply serrate, pointed, smoother on the upper than on the under surface, and of a dark green color, which is paler beneath. The flowers are small, purple, and in terminal obtuse spikes, interrupted below, and cymosely arranged. Late in the season, the growth of the lateral lower branches often gives to the inflorescence the appearance of a corymb. The calyx is tubular, often purplish, furrowed, glabrous below, and five-toothed, the teeth being hirsute. The corolla is purplish, tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its summit. The four short stamens are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The plant should be cut for medicinal use in dry weather, in August, about the period of the expansion of the flowers. John C. Umney points out differences between white and black peppermint in *P. J.*, 1896, 123. For a paper on the histology of powdered peppermint by Smith Ely Jelliffe, see *D. C.*, 1899, 252.

Properties.—It is officially described as follows: "Leaves more or less crumpled and frequently detached from the stems; stems quadrangular, from 1 to 2 mm. in diameter, glabrous except for a few scattered deflexed hairs; leaves when entire ovate-oblong to oblong-lanceolate, petioles from 4 to 15 mm. in length, slightly pubescent, laminæ from 1 to 9 cm. in length, acute and sharply serrate, light green to purplish-brown, upper surfaces nearly glabrous, lower surfaces glandular hairy, especially on the veins; flower-whorls in oblong or oval spikes which are usually compact, or somewhat interrupted at the base, from 1 to 1.5 cm. in breadth, rounded at the summit, and in fruit attaining a length of from 3 to 7 cm.; bracts oblong-lanceolate, very acuminate, 7 mm. in length; calyx tubular, equally 5-toothed, pubescent and glandular-punctate, often dark purple in color; corolla tubular-campanulate, 4-cleft, about 3 mm. in length and often light purple; stamens 4, short and equal; nutlets ellipsoidal, about 0.5 mm. in diameter, blackish-brown; odor aromatic, characteristic; taste aromatic, pungent, followed by a cooling sensation in the mouth." *U. S.*

The morphology of *Mentha piperita* and other species of *Mentha* are discussed by Eriksson in *B. P. G.*, xviii, p. 244. The herb, both in

the recent and in the dried state, has a peculiar, penetrating, grateful odor. Peppermint is quite frequently contaminated with spearmint and in one instance the leaves of belladonna were found. The latter, while no doubt accidental, shows the necessity for the examination of crude drugs generally. (*Pharm. Prax.*, iv, p. 38.) There is sometimes difficulty in distinguishing between the leaves of *M. piperita* and those of *M. spicata*. According to Joseph Schrenk, crystals can always be found in the glandular hairs of the peppermint, but are absent in those of the spearmint. The crystals are doubly refractive, and so transparent that sometimes a polariscope is necessary for their easy detection. These crystals have been thought to be menthol, but they seem not to dissolve in alcohol, and are probably hesperidin.

The medicinal properties depend on a volatile oil, of which from 1 to 1.25 per cent. can be obtained from the herb. The leaves are said to contain a little tannic acid. The virtues of the herb are imparted to water, and more readily to alcohol.

Uses.—Peppermint is an aromatic stimulant, much used to allay *nausea*, relieve *spasmodic pains of the stomach and bowels*, expel *flatus*, or cover the taste or qualify the nauseating or griping effects of other medicines. The medicine is rarely used in infusion. (See *Oleum Menthæ Piperitæ*.)

Dose, one drachm (3.9 Gm.).

Off. Prep.—Spiritus Menthæ Piperitæ, *U. S.*

MENTHA VIRIDIS. U. S.

SPEARMINT Menth. Vir.

(mĕn'thą vĭr'ĭ-dĭs)

"The dried leaves and flowering tops of *Mentha spicata* Linné (*Mentha viridis* Linné) (Fam. *Labiatæ*)." *U. S.*

Herba Menthæ Acutæ (vel Romanæ); Brown, Lamb, Garden, or Mackerel Mint; Menthe verte, *Fr. Cod.;* Menthe romaine, Baume vert, Menthe à épi, *Fr.;* Grüne Münze, Römische Minze, *G.*

Spearmint, sometimes called simply *mint*, differs from *M. piperita* chiefly in having sessile, or nearly sessile, oblong or ovate-lanceolate, unequally serrate leaves; elongated, interrupted, panicled spikes; setaceous bracts; and stamens longer than the tube of the corolla. It is a native of Europe and Asia, and naturalized in waste places from Nova Scotia and Ontario to Minnesota and Kansas in the West and Florida in the South United States. It is also cultivated for domestic use and for the sake of its oil. Its flowering season is August. Spearmint is officially described as "leaves more or less crumpled and mixed with a large proportion of the light brown or purplish-colored stems, occasionally with their characteristic opposite branches; stems distinctly quadrangular, from 1 to 3 mm. in width, nearly glabrous; leaves when entire ovate-lanceolate, unequally serrate, nearly sessile or with a petiole less than 5 mm. in length, of a bright green color and somewhat glandular-hairy on the under surface; flowers arranged in opposite clusters and in more or less interrupted or crowded lanceolate, nearly acute spikes; bracts linear-lanceolate, subulate, from 7 to 10 mm. in length, subtending the flower clusters; calyx tubular, 5-toothed, glandular punctate and somewhat pubescent near the teeth; corolla nearly white or light brown; stamens extending beyond the corolla tube; odor slightly pungent, characteristic; taste aromatic, characteristic but not followed by a cooling sensation in the mouth." *U. S.*

Spearmint was cultivated in the Convent gardens of the ninth century. It is largely used as a domestic and popular flavor in foods, chewing gum, and confectionery. The plant is widely cultivated, and Schimmel and Co. present a review of its cultivation in Michigan, Indiana and New York in their *Schim. Rep.*, October, 1910, p. 131. Recently experiments have been conducted in Louisiana, and Phenis states the resulting oil to be of the highest grade. (*Paint, Oil, and Drug Review*, xlvi, p. 27.) Successful experiments have also been conducted in Wisconsin. (*Ibid.*, xliv, p. 18.) Mitlacher has reported that *Mentha crispa* can be successfully grown in Austria. (*Ph. Post*, xliv, p. 215.)

Spearmint is sometimes admixed with peppermint. This is probably due to carelessness. The taste and odor of spearmint are retained for some time by the dried plant. They depend on a volatile oil. (See *Oleum Menthæ Viridis*.)

Dose, one drachm (3.9 Gm.).

Off. Prep.—Spiritus Menthæ Viridis, *U. S.*

MENTHOL. U. S., Br.

MENTHOL

(mĕn'thŏl)

"A secondary alcohol [$C_{10}H_{19}OH = 156.16$] obtained from oil of peppermint or other mint oils. Preserve it in well-closed containers, in a cool place." *U. S.* "Menthol, $C_{10}H_{20}O$, is a crystalline substance obtained by cooling the oil distilled from the fresh herb of Mentha arvensis, *DC., vars.* piperascens et glabrata, *Holmes;* and probably other species of Mentha." *Br.*

Pipmenthol, Peppermint Camphor; Menthol, *Fr. Cod.;* Camphre de Menthe, Mentholum, *Fr.;* Mentholum, *P. G.;* Menthol, Pfefferminzkampher, Mentha-Kampher, Pipmenthol, *G.;* Mentolo, *It.;* Mentol, *Sp.*

Menthol, or *peppermint camphor*, may be obtained from either American or *Japanese oil of peppermint* (*Mentha arvensis*), by cooling the oil to a very low temperature, when the menthol crystallizes out, often in a dense mass; the adhering oil may be separated by expression. Menthol may also be obtained by fractional distillation, and there is reason to believe that the oil of peppermint of commerce is often contaminated with the dementholized oil. A larger yield of menthol is obtained from Japanese or Chinese oils, and for this reason Japanese menthol is largely found in commerce. It is practically identical with American menthol,

differing, however, in the character of its crystals, which occur in small prisms instead of in long needles.

Properties.—The U. S. P. describes it as in "colorless, acicular or prismatic crystals, having a strong odor and taste of peppermint; when tasted it produces a sensation of warmth followed by cold when air is drawn into the mouth. Menthol is slightly soluble in water; very soluble in alcohol, chloroform, ether or in petroleum benzin; freely soluble in liquid petrolatum or fixed volatile oils. Its alcoholic solution is neutral to litmus, and is lævorotatory. It melts between 42° and 44° C. (107.6° and 111.2° F.). When Menthol is triturated with about an equal weight of camphor, thymol, or hydrated chloral, the mixture becomes liquid. Heat about 2 Gm. of Menthol in an open dish, on a water bath; it gradually volatilizes without leaving more than 0.05 per cent. of residue (*wax, paraffin, or inorganic substances*). Dissolve a few crystals of Menthol in 1 mil of glacial acetic acid and then add 3 drops of sulphuric acid and 1 drop of nitric acid; no green color is produced (*thymol*)." *U. S.*

"Colorless acicular crystals or crystalline masses. Melting point 42° to 43° C. (107.6°–109.4° F.). Odor and taste recalling peppermint; produces a sensation of warmth on the tongue and, if air is inhaled, a sensation of cold. Entirely volatilised by the heat of a water-bath. Very slightly soluble in *water;* but readily soluble in *alcohol* (90 per cent.), the solutions being neutral to *litmus.* Boiled with *sulphuric acid* diluted with half its volume of *water,* Menthol acquires an indigo-blue or ultramarine color, the acid becoming brown." *Br.*

Menthol is a stearopten and belongs to the class of camphors. Its formula may be written $C_{10}H_{19}OH$ (for structural formula see under *Olea Volatilia,* p. 732), as it is recognized as being a saturated secondary alcohol. Chromium trioxide oxidizes menthol to *dextro-* and *lævo-menthone,* $C_{10}H_{18}O$, which is the ketone corresponding. The *menthones* are liquids, with an odor resembling that of peppermint. They boil at 207° C. (404.6° F.). Distillation with zinc chloride or phosphoric anhydride changes menthol into liquid *menthene,* $C_{10}H_{18}$, boiling at 167° C. (332.6° F.). (See papers by Kremers, Urban, and Richtmann on the menthol group, *Proc. A. Ph. A.,* 1893, 185; also 1896, 200.) Menthol has been grossly adulterated with spermaceti, paraffin, etc., and, after being compressed into pencils or cones, sold as a local panacea for headache and neuralgia.

Uses.—According to Schwenkenbecher (*M. M. W.,* 1908, lv, p. 1495), menthol in large doses is a narcotic, paralyzing eventually both the sensory and motor systems. It cannot, however, be regarded as highly toxic, for he himself, took 8 Gm. within a period of two hours without suffering serious symptoms. When locally applied it stimulates the nerves for the perception of cold, but depresses those for pain. It is actively antibacterial; according to McDonald, it is about twice as powerful as phenol. Menthol is used for its local anesthetic influence in various *skin diseases,* accompanied with *itching,* such as *urticaria.* Probably by virtue of the same property it is also frequently of service in *nausea* and *gastrodynia.* In *headache* and other forms of *neuralgia* the external application of menthol will frequently produce considerable degree of relief; the action in these cases is probably that of a counter-irritant rather than anesthetic. A solution containing one or two per cent. of menthol in liquid petrolatum is very widely employed for its antiseptic and anesthetic influence in inflammations of the upper respiratory tract, such as *acute coryza, pharyngitis,* or *laryngitis.* It is also occasionally employed as a gastro-intestinal antiseptic. According to S. A. Russel an ethereal solution of from 10 to 50 per cent. applied 2 or 3 times a day has a remarkable power of controlling superficial inflammations, such as *boils* or *carbuncles.* Berliner (*B. K. W.,* 1910, p. 967) and others have injected, hypodermically, its oily solution with asserted benefit in various forms of *tuberculosis.* A number of cases of dangerous asphyxiation, at least one of which ended fatally, have followed the local application of menthol in infants for the relief of *coryza.* (See Lublinski, *B. K. W.,* 1912, xlix.)

Dose, one to two grains (0.065–0.13 Gm.).

METHYLIS SALICYLAS. U. S. (Br.)

METHYL SALICYLATE Methyl. Salicyl. [Oleum Gaultheriæ, U. S. VIII, Oil of Wintergreen, Oleum Betulæ, U. S. VIII, Oil of Sweet Birch, Oil of Teaberry, Methyl Salicylas, U. S., 1890, Synthetic Oil of Gaultheria, Synthetic Oil of Wintergreen]

(mĕth'ĭl-ĭs săl-ĭ-cĭ'lăs)

"It contains not less than 98 per cent. of $CH_3C_7H_5O_3$ (152.06). It is produced synthetically or is obtained by distillation from *Gaultheria procumbens* Linné (Fam. *Ericaceæ*) or from *Betula lenta* Linné (Fam. *Betulaceæ*). The label must indicate whether the methyl salicylate has been made synthetically or distilled from either of the above mentioned plants. Preserve it in well-stoppered amber-colored bottles, in a cool place, protected from light." *U. S.* "Methyl Salicylate is the methyl ester of salicylic acid. It may be obtained by the interaction of methyl alcohol and salicylic acid. It contains not less than 98 per cent. of pure methyl salicylate, $CH_3C_7H_5O_3$." *Br.*

Methyl Salicylas, *Br.;* Salicylate de Méthyle, *Fr.;* Methylsalicylat, Künstliches Wintergrünöl, *G.*

Methyl salicylate, or *artificial oil of wintergreen,* was introduced into the U. S. P., 1890,

largely because of its extensive use and on account of its being a valuable synthetic; it is asserted that it can be produced of more uniform quality and is more definite and certain in its action than either the oil from gaultheria or the oil from birch, which are natural oils. (See *A. J. P.*, 1889, p. 398; *Ph. Rund.*, 1889, 283; see also 1892, p. 7, 9.) Many investigators have attempted to devise tests for differentiating the oils of wintergreen and birch and methyl salicylate, but as soon as a reaction is proposed and described, its unreliability is quickly proved by other investigators. A method is said to have been discovered in the Bureau of Chemistry, U. S. Dept. of Agriculture, which has not yet been made public, but which has been used with success unofficially. Vanillin and alcohol, heliotropin and sulphuric acid, chloral hydrate and sulphuric acid, are among the reagents which have been proposed, none of which seem to be infallible with mixtures, although they do show decided differences with the pure oils. References to some of the articles on this subject are as follows: *Schim. Rep.*, 1914, Apr., p. 99; *J. A. Ph. A.*, 1914, p. 1658; *J. A. Ph. A.*, 1914, p. 1284. Methyl salicylate may be made by distilling salicylic acid or a salicylate, with methyl alcohol and strong sulphuric acid. The reaction is as follows:

$$C_6H_4OHCOOH + CH_3OH = C_6H_4OHCOOCH_3 + H_2O.$$

The sulphuric acid plays no part in the reaction except to serve as a dehydrating agent. The following process was devised by G. M. Beringer (*A. J. P.*, 1887, p. 8). Dissolve half an ounce of salicylic acid in two fluidounces of absolute methyl alcohol, then gradually add one fluidounce of sulphuric acid; warm gently for twenty-four hours, then distil from a retort into which a current of steam is introduced. The distillate is to be well washed, and separated by decantation. The odor improves with age. Methyl salicylate has been found in a great number of plants. (See *A. J. P.*, 1898, 412; *Ph. Rev.*, 1898, 130; *Schim. Rep.*, 1898, 45; 1899, 46.)

Properties.—Methyl salicylate is officially described as "a colorless, yellowish or reddish liquid, having the characteristic odor and taste of gaultheria. It is sparingly soluble in water; miscible with alcohol and glacial acetic acid. It is soluble in 6 volumes of 70 per cent. alcohol at 25° C. (77° F.) with not more than a slight cloudiness. The alcoholic solution is neutral or slightly acid to moistened litmus paper. Specific gravity at 25° C. (77° F.): synthetic, 1.180 to 1.185; when from sweet birch or gaultheria, 1.172 to 1.182. It boils between 218° and 221° C. (424.4° and 429.8° F.). Synthetic Methyl Salicylate, or that from sweet birch, is optically inactive; when obtained from gaultheria, it is slightly lævorotatory, not exceeding –1.5° in a 100 mm. tube at 25° C. (77° F.). A deep violet color is produced by shaking a drop of Methyl Salicylate with about 5 mils of distilled water and adding a drop of ferric chloride T.S. Add 10 mils of potassium hydroxide T.S. to 1 mil of Methyl Salicylate, contained in a capacious test tube, and agitate the mixture. A clear, or slightly cloudy, colorless or faintly yellowish solution results without the separation of any oily drops either on the surface or at the bottom of the liquid (*other volatile oils or petroleum products*). It does not respond to the Test for heavy metals in volatile oils (see Part III, Test No. 3)." *U. S.*

"A colorless liquid. Characteristic, aromatic odor; taste sweetish, warm, aromatic. Slightly soluble in *water;* readily soluble in *alcohol* (90 per cent.), in *glacial acetic acid,* and in *carbon disulphide.* Specific gravity 1.185 to 1.192. Boiling point from 219° to 221° C. (426.2°–429.8° F.). Optically inactive. The solution in *alcohol* (90 per cent.) is neutral or faintly acid to *litmus.* The aqueous solution is colored violet by the addition of a drop of *T. Sol. of ferric chloride.* Contains not less than 98 per cent. of the *ester* methyl salicylate, $CH_3C_7H_5O_3$." *Br.*

"**Assay.**—Introduce about 2 mils of Methyl Salicylate into a tared flask, note the exact weight, add 50 mils of half-normal alcoholic potassium hydroxide V.S., connect the flask with a reflux condenser and heat the mixture on a water bath during two hours. Then add a few drops of phenolphthalein T.S. and titrate the excess of alkali with half-normal hydrochloric acid V.S. It shows not less than 98 per cent. of $CH_3C_7H_5O_3$.

"Each mil of half-normal alcoholic potassium hydroxide V.S. consumed corresponds to 0.07603 Gm. of $CH_3C_7H_5O_3$. Each gramme of Methyl Salicylate corresponds to not less than 12.9 mils of half-normal alcoholic potassium hydroxide V.S." *U. S.*

Uses.—Methyl salicylate is used chiefly in the treatment of various forms of *rheumatism* in which other preparations of salicylic acid are of service. It has the advantage over the inorganic salicylates of being less unpleasant to the taste, but in our experience is somewhat more prone to cause digestive disturbances. Because of its volatility it is capable of being absorbed through the skin and is frequently applied externally for its systemic effect. For this purpose it may be mixed with equal parts of lard and a drachm of the mixture spread over a surface as big as the palm of the hand and covered with an impermeable dressing to prevent evaporation. It is also employed for its counter-irritant action in various liniments. As a flavoring agent two minims may be used for each fluidounce.

Internally it is best administered in emulsion, although sometimes taken by dropping into a teaspoonful of sugar. The custom of giving it in capsules is to be deprecated as it is much more likely to irritate the stomach under these circumstances.

Dose, from five to twenty minims (0.3–1.2 mils).

Off. Prep.—Inunctum Mentholis Compositum, *N. F.;* Liquor Antisepticus, *N. F.;* Liquor Antisepticus Alkalinus, *N. F.;* Liquor Ferri Salicylatis, *N. F.;* Liquor Pepsini Antisepticus, *N. F.;* Nebula Aromatica, *N. F.;* Nebula Mentholis Composita, *N. F.;* Petroxolinum Methylis Salicylatis, *N. F.*

METHYLTHIONINÆ CHLORIDUM. U. S.

METHYLTHIONINE CHLORIDE Methylthionin. Chlor. [Methylene Blue Methylthioninæ Hydrochloridum, U. S. VIII]

(mĕth-ȳl-thī-o-nī'næ ȼhlō'rı̤-dŭm)

"Tetramethylthionine chloride [$C_{16}H_{18}N_3ClS + 3H_2O = 373.75$]." *U. S.*

Chlorhydrate de Tetraméthylthionine, *Fr.;* Tetramethylthioninchlorid, Methylen Blau, *G.*

This synthetic dye color belongs to the class of *thiazines* or dyestuffs in which two benzene nuclei are united by a nitrogen atom and a sulphur atom. *Methylene blue* was discovered by Caro in 1876, and was made by the oxidation of *p*-amido-dimethyl aniline with ferric chloride in the presence of hydrogen sulphide. Both the hydrochloride of the base and the zinc chloride double salt of the same are known by the name of methylene blue. It is only the former that is used in medicine and constitutes the official salt. Methylene Blue must not be confounded with *methyl blue,* a dark blue powder which is used as an antiseptic; the latter is sodium triphenyl-pararosaniline-sulphonate.

Properties.—Methylene blue is officially described in the United States Pharmacopœia as "a dark green, crystalline powder, or in prismatic crystals having a lustre resembling bronze. Methylthionine Chloride is freely soluble in water and alcohol; soluble in chloroform; the solutions have a deep blue color. The addition of hydrochloric acid to its aqueous solution changes the color to a lighter shade of blue. The addition of sodium hydroxide T.S. to its aqueous solution changes the color to a purplish shade, and, if added in excess, produces on standing a precipitate having a dull violet color. A solution of Methylthionine Chloride in diluted sulphuric acid is gradually decolorized upon the addition of zinc dust. Incinerate about 0.5 Gm. of Methylthionine Chloride; not more than 1 per cent. of ash remains. Intimately mix 0.2 Gm. of Methylthionine Chloride with about 0.5 Gm. each of potassium nitrate and anhydrous sodium carbonate and heat the powdered mixture in a crucible until the organic matter is completely oxidized. Then dissolve the cooled residue in 15 mils of diluted sulphuric acid and evaporate the solution over a flame until vapors of sulphuric acid begin to evolve. The residue so obtained meets the requirements of the Test for arsenic (see Part III, Test No. 1). Heat about 0.5 Gm. of Methylthionine Chloride at a temperature below a red heat until it is completely carbonized, boil the powdered residue with 10 mils of diluted hydrochloric acid for five minutes, filter the liquid and wash the residue with 10 mils of distilled water. The combined liquids, when boiled with 1 mil of nitric acid, and supersaturated with ammonia water and filtered, if necessary, remain clear upon the addition of an equal volume of hydrogen sulphide T.S. (*zinc*). Dissolve 1 Gm. of Methylthionine Chloride in 50 mils of boiling alcohol, filter through counter-balanced filters, wash the residue on the filter with boiling alcohol until the washings cease to be colored blue, and dry it at 100° C. (212° F.). The weight corresponds to not more than 1 per cent. (*dextrin*)." *U. S.*

Uses.—When taken internally methylene blue is absorbed and eliminated chiefly from the kidneys, coloring the urine blue or greenish. In therapeutic doses it produces no symptoms except occasionally some irritation of the bladder, and we know of no serious cases of poisoning with the pure article. It is a feeble antiseptic and has been used to a considerable extent in *gonorrhea, cystitis* and *pyelitis,* but its value is certainly not great. As an analgesic, it has been employed in *neuralgia, locomotor ataxia,* etc., but is inferior to other aniline derivatives. In 1891, Ehrlich and Guttmann (*B. K. W.,* xxviii), led by its power as a staining agent over the plasmodium malariæ, suggested its practical use as an antiperiodic, and its value as such is well established. In 425 cases collected by H. C. Wood, Jr. (*Trans. Phila. County Med. Soc.,* 1904), there were 85 per cent. of cures. It does not produce disturbances of the special senses or of the gastro-intestinal tract, and therefore may be preferable to quinine in aural or gastro-intestinal affections. Further, on account of its lack of action upon the kidney, it is especially valuable in those forms of *malaria* accompanied with *hematuria,* the so-called "*black water fever.*" If the statement of Iwanoff, that it especially acts upon the adult forms of plasmodium be correct, it should be especially valuable in *chronic malaria,* and experience may prove that the best treatment of this condition is the administration of full doses of quinine at intervals of seven days, with the continuous use of the methylene blue. Slack (*Atlanta Journal and Record of Medicine,* 1907) recommends the internal use of methylthionine in *carcinoma;* it seems not only to relieve the pain but also to delay the growth of the tumor.

Methylene blue is preferably administered in capsule. In malaria from ten to twenty grains (0.65–1.3 Gm.) may be given in the course of a day for ten days, and after this six to ten grains (0.4–0.65 Gm.) a day for two weeks. In obstinate cases a full dose of quinine may be exhibited every seventh day, the methylene blue being omitted. The staining action of methylene blue upon any portion of the body or clothing with which it may come in contact, and its color effect upon the urine, should always be explained to the patient.

Dose, two to five grains (0.13–0.32 Gm.).

MEZEREUM. U. S.

MEZEREUM [Mezereon]

(mẹ-zē′rē-ŭm)

"The dried bark of *Daphne Mezereum* Linné, *Daphne Gnidium* Linné, or of *Daphne Laureola* Linné (Fam. *Thymeleaceæ*)." *U. S.*

Mezerei Cortex, *Br.* 1898; Mezereon Bark; Cortex Mezerei, Cortex Thymeleæ (vel Coccognidii); Dwarf Bay, Wild Pepper, Spurge-flax, Spurge-olive, Magell; Mézéréon ou Bois gentil, *Fr. Cod.*; Lauréole, Thymelée, *Fr.*; Kellerhals, Seidelbastrinde, Kellerhalsrinde, *G.*; Mezereo, *It.*; Mecereon, *Sp.*

All the species of *Daphne* are possessed of active properties, but three only are official—*D. Mezereum, D. Laureola,* and *D. Gnidium,* all of which are recognized in the United States Pharm., and the last in the former French Codex, 1884.

1. *Daphne Mezereum* is a very hardy, low shrub, with a branching stem, and a smooth, dark gray bark, very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate-lanceolate, entire, smooth, and of a pale green color, somewhat glaucous beneath. They are preceded by the flowers, which appear very early in the spring, and sometimes bloom even amidst the snow. These are of a purple-rose color, rarely white, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red color, and contains a single round seed. Another variety produces white flowers and yellow fruit. This species of *Daphne* occurs throughout the forests of Europe, and extends in Western Asia from the Caucasus to the Altai. It is cultivated in Europe, and is occasionally found in our own gardens. *D. Mezereum* is locally naturalized from New York and Massachusetts to western Quebec and Ontario.

2. *Daphne Gnidium.*—In this species, called *garou* or *sain-bois* by the French, the leaves are linear-lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicled racemes. The fruit is globular, dry, at first green, but ultimately black. *D. Gnidium* grows in dry uncultivated places in the south of Europe, and flowers in June. Its bark, which in France is used indiscriminately with that of the former species, is of a deep purplish-brown color, and hairy in the younger portions. It appears to be equally as active, medicinally, as the other official species.

Besides the species above described, *Daphne Laureola,* or *spurge laurel,* is said to furnish a portion of mezereum of commerce, and is recognized by the U. S. Pharmacopœia, but its product is inferior in acrimony, and consequently in medicinal activity.

Properties.—The bark of the root was formerly directed, but the mezereum with which our markets are supplied is evidently the bark of the stem, and the Pharmacopœias at present very properly direct the bark, without designating the part from which it must be taken. The official description is as follows: "In flexible, tough quilled pieces or somewhat flattened strips, attaining a length of 90 cm.; from 0.3 to 1 mm. in thickness; outer surface yellowish- or olive-brown (*D. Mezereum*) or purplish-brown (*D. Gnidium*) or purplish-gray (*D. Laureola*), smooth, numerous lenticels giving a transversely striated appearance and occasionally with numerous, circular, brownish-black apothecia; outer corky layer easily separable from the middle bark which varies from light green to olive-brown and with more or less detached bast-fibers; inner surface yellowish-white, satiny lustrous, finely striate; fracture tough, fibrous, the inner bark lamellated; odor very slight; taste at first slight, becoming gradually and increasingly pungent and acrid. Under the microscope, transverse sections of Mezereum show a rather thick cork composed of from 20 to 30 rows of cells, the outer being compressed and with yellowish-brown walls, and the inner more or less tabular with nearly colorless walls; a hypodermis of 3 to 5 rows of collenchymatous cells containing chloroplastids or a yellowish-green resinous substance; an inner bark consisting mostly of nearly colorless non-lignified bast-fibers occurring in loosely united groups, and a few starch-bearing medullary rays one cell in width. The powder is light grayish-brown; bast-fibers numerous, from 0.4 to 3 mm. in length and about 0.015 mm. in width, frequently more or less uneven or irregularly bent and considerably attenuated at the ends, the walls being from 0.001 to 0.005 mm. in thickness, colorless, non-lignified and free from pores; fragments of yellowish-brown cork cells and starch-bearing medullary rays; starch grains relatively few, mostly spherical or elliptical, occasionally 2- to 4-compound, the individual grains from 0.003 to 0.015 mm. in diameter." *U. S.*

British writers state that the bark of the root is the most active. The berries and leaves of the plant are also active, and the former have sometimes proved fatal to children who have eaten them. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to act. French authors observe that fifteen are sufficient to kill. A tincture of them is used in Germany as a local application in *neuralgia.*

Vauquelin discovered a peculiar principle in the bark of *Daphne alpina.* This has subsequently been found in other species, and has received the name of *daphnin.* Gmelin and Bär found it in the bark of *D. Mezereum,* associated with wax, an acrid resin (*mezerein*), a yellow coloring matter, a reddish-brown extractive, and uncrystallizable and fermentable sugar, a gummy matter containing nitrogen, ligneous fiber, malic acid, and several malates. By J. B. Eng it has been discovered, together with a vola-

tile oil, in the flowers of *D. Mezereum.* (*Wittstein's Viertelj.*, viii, 23.) *Daphnin* is in prismatic crystals, grouped together, colorless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water and alcohol, without odor, and of a bitter, somewhat harsh taste. According to Zwenger (*Ann. Ch. Ph.*, 1860, cxv, 1) it is a glucosidal acid, being resolvable by sulphuric or hydrochloric acid into sugar, and a peculiar crystallizable principle called *daphnetin*, $C_9H_6O_4 + H_2O$. He gives for daphnin the formula $C_{15}H_{16}O_9 + 2H_2O$, the same as that of *æsculin*, of which it is, therefore, an isomer. W. Will and O. Jung (*A. J. P.*, 1885) have investigated daphnetin, which was shown in 1879 by Stünkel to be *dioxycoumarin*,

$$C_6H_2(OH)_2\begin{cases} O & -CO \\ & | \\ CH & =CH \end{cases}$$

; they obtained but about one ounce of daphnetin from fifty pounds of extract of mezereum, and they proved that it has the same relation to pyrogallic acid that coumarin has to phenol, or umbelliferone to resorcinol. (For a method of preparing the glucoside daphnin, see *U. S. D.*, nineteenth edition, p. 781.) *Coccognin*, isolated in 1870 by Casselmann from the fruits of *D. Mezereum*, appears to be closely allied to, if not identical with, daphnin. By the dry distillation of an alcoholic extract of mezereum bark, Zwenger obtained *umbelliferone*, $C_9H_6O_3$.

Uses.—The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic, from time immemorial, in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues. A small square piece, moistened with vinegar, is applied to the skin, and renewed twice a day until a blister is formed, and occasionally afterwards to keep up the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. The ointment was formerly used for maintaining the discharge from blistered surfaces, and may be applied advantageously to obstinate, ill-conditioned indolent *ulcers*. It was recognized by the U. S. 1880. (See *U. S. D.*, 19th ed., p. 781, for formula.)

An alcoholic extract has also been employed to communicate irritant properties to issue-peas. Internally administered, mezereum is a stimulant capable of being directed to the skin or kidneys, and in large doses likely to excite purging, nausea, and vomiting. In overdoses it produces the fatal effects of the acrid poisons, and a case of apparently severe narcotic effects has been recorded. (*Am. J. M. S.*, xxi.) It had at one time much reputation as an alterative in *syphilis, chronic rheumatism*, etc., but is of no value as an internal remedy and is almost never administered save as an ingredient of the compound fluidextract of sarsaparilla.

Dose, ten grains (0.65 Gm.).

Off. Prep.—Fluidextractum Sarsaparillæ Compositum, *U. S.*; Decoctum Sarsaparillæ Compositum, *N. F.*; Fluidextractum Mezerei, *N. F.*; Linimentum Sinapis Compositum (from Fluidextract), *N. F.*

MISTURA AMMONIACI. Br.

AMMONIACUM MIXTURE

(mĭs-tū'rą ăm-mo-nī'ą-cī)

Emulsum Ammoniaci, U. S. 1890, Emulsion of Ammoniac; Ammoniac Mixture; Emulsio Ammoniaci, Lac Ammoniaci; Milk of Ammoniac; Mixture de Gomme ammoniaque, *Lat;* d'ammoniaque, *Fr.;* Ammoniak-Emulsion, *G.*

"Ammoniacum, in coarse powder, 30 *grammes;* Syrup of Tolu, 60 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Triturate the Ammoniacum thoroughly with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water and the Syrup of Tolu, triturating until the mixture assumes a uniform milky appearance; strain through muslin." *Br.*

In this emulsion the resinous and oily constituents are suspended by means of the gum of the ammoniac, imparting a milky appearance to the preparation, which from this circumstance was formerly called *lac ammoniaci*, or *milk of ammoniac.* The greater portion of the resin subsides upon standing. This emulsion is no longer official in the U. S. P. IX, the process of the U. S. P., 1890, is as follows:

Emulsum Ammoniaci, U. S. 1890. *Emulsion of Ammoniac.*—"Ammoniac, *forty grammes* [or 1 ounce av., 180 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the Ammoniac, in a warmed mortar, with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*, 1890.

The British Pharmacopœia (1898) process directs the addition of a small quantity of syrup of Tolu, doubtless as a flavoring agent. The mixture is slightly curdled by acids.

Dose, one-half to a fluidounce (15–30 mils).

MISTURA CRETÆ. U. S., Br.

CHALK MIXTURE Mist. Cret.

(mĭs-tū'rą crē'tæ)

Mixture avec la Craie, *Fr.;* Kreidemixtur, *G.*

* "Compound Chalk Powder, *twenty grammes* [or 309 grains]; Cinnamon Water, *forty mils* [or 1 fluidounce, 169 minims]; Water, *a sufficient quantity*, to make *one hundred mils* [or 3 fluidounces, 183 minims]. Gradually add the cinnamon water and about *twenty mils* [or

325 minims] of water to the compound chalk powder in a mortar, triturating until the mixture is uniform; transfer this to a graduated vessel, rinse the mortar with enough water to make the product measure *one hundred mils* [or 3 fluidounces, 183 minims], and mix the whole thoroughly. This preparation must not be dispensed unless it has been recently prepared." *U. S.*

"Prepared Chalk, 30 *grammes;* Tragacanth, in powder, 5 *grammes;* Refined Sugar, 60 *grammes;* Cinnamon Water sufficient to produce 1000 *millilitres.* Triturate the Prepared Chalk with the Tragacanth and Refined Sugar, and gradually add, with constant trituration, sufficient Cinnamon Water to produce the required volume." *Br.*

The direction that this mixture be prepared extemporaneously is a decided improvement. Unsuccessful attempts have been repeatedly made to devise a formula which would yield a permanent product, and much injury has been done through the dispensing of chalk mixture in an incipient fermentative condition. The trifling amount of glycerin present in the chalk mixture official in 1870 was totally inadequate to preserve it during the warm summer months, when it is in greatest vogue. Compound Chalk Powder is official (see *Pulvis Cretæ Compositus*); it will keep indefinitely, and, besides being itself a valuable addition to the materia medica, is quickly made into chalk mixture by rubbing it with the water and cinnamon water, so that there can be no excuse for not dispensing a fresh mixture. This mixture is a convenient form for administering chalk, and is much employed in *looseness of the bowels* accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency.

Dose, four fluidrachms (15 mils), frequently repeated.

MISTURA FERRI COMPOSITA. Br.

COMPOUND IRON MIXTURE [Griffith's Mixture]

(mĭs-tū'rą fĕr'rī cŏm-pŏz'ĭ-tą)

Mixture ferrugineuse de Griffith, *Fr.;* Griffithsche Eisenmixtur, *G.*

This mixture was dropped from the U. S. P. IX; but is included in the N. F. IV. (See Part III.)

"Ferrous Sulphate, in powder, 6 *grammes;* Potassium Carbonate, 8 *grammes;* Myrrh, 15 *grammes;* Gum Acacia, in powder, 15 *grammes;* Glucose, 15 *grammes;* Spirit of Nutmeg, 10 *millilitres;* Rose Water, sufficient to produce 1000 *millilitres.* Powder the Myrrh; add the Potassium Carbonate, Glucose, and Gum Acacia; triturate the mixture with a small quantity of the Rose Water so as to form a thin paste; gradually add more Rose Water and the Spirit of Nutmeg; continue the trituration and further addition of Rose Water until one thousand *millitres* of liquid are produced; add the Ferrous Sulphate and shake until dissolved." *Br.*

This is very nearly the same as the celebrated tonic or anti-hectic myrrh mixture of Griffith. The ferrous sulphate is decomposed by the potassium carbonate, with the production of potassium sulphate and ferrous carbonate, while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish color, which it loses upon exposure to the air, in consequence of the conversion of the ferrous carbonate into the ferric compound. The official solution may, however, be kept for some time without change, if the vessel in which it is contained be well closed, but the best plant is to prepare it extemporaneously. The sugar contained in it helps somewhat to retard the further oxidation of the ferrous salt, and if considerably increased in amount would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down with a little of the rose water, as the powdered myrrh of commerce is often impure, and otherwise does not make a good mixture, owing mainly to its loss of volatile oil.

This mixture is used in *anemia,* especially when attended with derangement of the menstrual function. It has been also employed in the hectic fever of *phthisis.* It is contra-indicated by the existence of inflammation of the gastric mucous membrane.

Dose, from one-half to two fluidounces (15–60 mils) two or three times a day.

MISTURA GLYCYRRHIZÆ COMPOSITA. U. S.

COMPOUND MIXTURE OF GLYCYRRHIZA Mist. Glycyrrh. Co. [Brown Mixture]

(mĭs-tū'rą glĭç-ĭr-rhī'zæ cŏm-pŏz 'ĭ-tą)

Mistura Fusca; Mixture de Réglisse, *Fr.;* Zusammengesetzte Lakritzenmixtur, *G.*

*"Pure Extract of Glycyrrhiza, *thirty grammes* [or 1 ounce av., 25 grains]; Syrup, *fifty mils* [or 1 fluidounce, 331 minims]; Acacia, granulated, *thirty grammes* [or 1 ounce av., 25 grains]; Antimony and Potassium Tartrate, *two hundred and forty milligrammes* [or 3½ grains]; Camphorated Tincture of Opium, *one hundred and twenty mils* [or 4 fluidounces, 28 minims]; Spirit of Nitrous Ether, *thirty mils* [or 1 fluidounce, 7 minims]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Rub the pure extract of glycyrrhiza and acacia in a mortar with *five hundred mils* [or 16 fluidounces, 435 minims] of warm water, until they are dissolved. Allow the solution to cool, transfer it to a graduated vessel, add the antimony and potassium tartrate, dissolved in *twelve mils* [or 195 minims] of hot water, then the other ingredients and rinse the mortar with enough water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly." *U. S.*

This is an exceedingly popular cough mixture, and has been official for many years. In the

U. S. P. IX a change was made by using a definite quantity of antimony and potassium tartrate instead of wine of antimony, because all wines were deleted. This is an improvement because wine of antimony as found in commerce was sometimes variable in quality.

The spirit of nitrous ether is probably useful by somewhat retarding decomposition. It has been suggested many times that this preparation be filtered and dispensed clear but the revisers of the Pharmacopœia have not considered it of sufficient importance to change the well-known appearance of the mixture and there are no advantages in making a *mixture* transparent. Commercial powdered extract, however, should not be used as it contains about 40 per cent. of insoluble matter and produces a very heavy precipitate. If pure extract is used as officially directed the mixture is but slightly cloudy (see *A. J. P.*, 1892, 563; *M. R.*, 1910, 253).

Uses.—The compound mixture of glycyrrhiza is used very frequently as a vehicle, especially in conjunction with the ammonium salts in the early stages of acute bronchitis. Its use in such manner, however, is not to be encouraged because of the presence of the antimony and opium. While the dose of the latter ingredients is so small that in a teaspoonful there will scarcely be sufficient to exercise any perceptible effect in the adult, yet their exhibition in unsuitable cases is certainly unwise. In large dose it acts as a nauseating expectorant and is sometimes given, especially in children, for its active effects in *bronchitis*. In our opinion, however, the combination is not a very happy one for this purpose.

Dose, from one-half to one fluidounce (15–30 mils) for an adult; one fluidrachm (3.75 mils) for a child two years old. It should be well shaken when administered.

MISTURA GUAIACI. Br.

GUAIACUM MIXTURE

(mĭs-tū'rą guā'ĭą-cī)

Emulsio Resinæ Guaiaci; Mixture de Résine de Gayac, Lait de Gayac, *Fr.*; Guajak-Emulsion, Guajakharzmixtur, *G.*

"Guaiacum Resin, 25 *grammes;* Refined Sugar, 25 *grammes;* Tragacanth, in powder, 5 *grammes;* Cinnamon Water, sufficient to produce 1000 *millilitres*. Triturate the Guaiacum Resin with the Refined Sugar and the Tragacanth; add gradually, with constant trituration, sufficient Cinnamon Water to produce the required volume." *Br.*

For the changes of color which the Guaiac in this mixture undergoes, and which it produces in other substances, see *Guaiaci Resina*, p. 539. Tragacanth was substituted for acacia in the Br. Ph., 1898, process. A similar preparation under this title is official in the N. F. IV. (See Part III.)

Dose, one-half to two fluidounces (15–60 mils), repeated two or three times a day, or more frequently.

MISTURA OLEI RICINI. Br.

CASTOR OIL MIXTURE

(mĭs-tū'rą ō'lę-ī rĭç'ĭ-nī)

Emulsion of Castor Oil; Emulsion d'Huile de Ricin, *Fr.*; Ricinusoelmixtur, *G.*

"Castor Oil, 375 *millilitres;* Gum Acacia, in powder, 100 *grammes;* Orange-flower water of commerce, undiluted, 150 *millilitres;* Cinnamon Water, sufficient to produce 1000 *millilitres*. Triturate the Castor Oil with the Gum Acacia in a dry mortar; add, in one portion, two hundred *millilitres* of Cinnamon Water, and continue the trituration until the oil is completely emulsified; then, with constant trituration, add the orange-flower water and sufficient Cinnamon Water to produce the required volume." *Br.*

Under the title *Emulsum Olei Ricini* a similar preparation is official in the N. F. IV. (See Part III.)

Dose, from one-half to two fluidounces (15–60 mils).

MISTURA SENNÆ COMPOSITA. Br.

COMPOUND MIXTURE OF SENNA

(mĭs-tū'rą sĕn'næ cŏm-pŏs'ĭ-tą)

Black Draught; Mixture de Séné composée, *Fr.*; Zusammengesetzte Senna-Aufguss, Zusammengesetzte Sennamixtur, *G.*

"Magnesium Sulphate, 250 *grammes;* Liquid Extract of Liquorice, 50 *millilitres;* Compound Tincture of Cardamoms, 100 *millilitres;* Aromatic Spirit of Ammonia, 50 *millilitres;* Infusion of Senna, sufficient to produce 1000 *millilitres*. Dissolve the Magnesium Sulphate in five hundred *millilitres* of the Infusion of Senna; add the mixed Liquid Extract of Liquorice, Compound Tincture of Cardamoms, and Aromatic Spirit of Ammonia, and sufficient Infusion of Senna to produce the required volume." *Br.*

This is a form of Compound Infusion of Senna, called commonly *black draught*, which term should never be used, as death has occurred through misreading prescriptions and dispensing *"black drop"* or vinegar of opium. We prefer the form given under *Infusum Sennæ Compositum*, as being more easily prepared and quite as efficient.

Dose (Br. Pharm.), from one to two fluidounces (30–60 mils).

MISTURÆ

MIXTURES

(mĭs-tū'ræ)

Mixtures, *Fr.*; Mixturen, *G.*; Mixtura, *Sp.*

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in aqueous fluids, by the intervention of gum arabic, sugar, yolk of egg, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is properly called an *emulsion*, and the

U. S. Pharmacopœia has recognized them by creating a special class for these. (See *Emulsa*, p. 419.) The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines, and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect mixtures. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the inter-medium, before the aqueous vehicle is added. In Great Britain, and to some extent in this country, the term mixture is used indiscriminately for aqueous medicinal liquids having more than one ingredient, and for aqueous liquids which cannot be easily classified. Many of such liquids are perfectly transparent and should be in the class of Solutions.

A study of the principles of colloid chemistry has been brought to bear upon the subject of pharmaceutical mixtures and their preparation, with great advantage (see *Emulsa*).

MORPHINA. U. S.

MORPHINE

(mör-phī'nȧ)

"An alkaloid [$C_{17}H_{19}O_3N + H_2O = 303.18$] obtained from opium. Preserve it in well-closed containers, protected from light." *U. S.*

Morphia, *U. S.* 1870; Morphinum, Morphium; Morphine, *Fr. Cod.*; Morphin, *G.*; Morfina, *It., Sp.*

The U. S. Pharmacopœia no longer contains a process for the extraction of morphine; that of 1870, which has been known as Staples's process, is given in the *U. S. Dispensatory*, 19th edition, p. 785.

Various processes for preparing morphine have been employed. In most of them the morphine is extracted from opium by maceration with water (either pure or acidulated), then precipitated by ammonia, and the crystals afterwards purified by the agency of alcohol, or by repeated solution in a diluted acid and precipitation. Sertürner, the discoverer of morphine, made an infusion of opium in distilled water, precipitated the morphine by ammonia in excess, dissolved the precipitate in diluted sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization. In evaporating aqueous solutions containing morphine a temperature of 40° C. (104° F.) should not be exceeded.

Properties.—Morphine crystallizes from alcohol in the form of small, colorless, shining crystals. It is officially described as follows: "Colorless or white, shining, rhombic prisms, in fine needles, or as a crystalline powder; odorless; permanent in the air. One Gm. of Morphine dissolves in 3340 mils of water, 210 mils of alcohol, 1220 mils of chloroform, 6250 mils of ether, and in 100 mils of lime water, at 25° C. (77° F.); also in 1075 mils of boiling water and 98 mils of boiling alcohol; insoluble in benzene. A saturated aqueous solution of Morphine is alkaline to litmus. One mil of sulphuric acid added to about 0.05 Gm. of Morphine produces either no color or at most only a red or yellow tint; on heating, a brown color is developed. Sulphuric acid containing 0.005 Gm. of selenous acid in each mil gives with Morphine a blue color, changing to green and then to brown. (Codeine yields a green color, changing to blue, and afterwards to grass-green; narcotine gives a green color, changing to brown and then to cherry-red.) Nitric acid produces with Morphine an orange-red color fading to yellow. Sulphuric acid containing 0.005 Gm. of molybdic acid in each mil gives a purple color, changing to blue. Sulphuric acid containing in each mil one drop of solution of formaldehyde yields an intense, purple color. Add a few drops of ferric chloride T.S. to a neutral solution of Morphine (1 in 100), made by the careful addition of diluted sulphuric acid; a blue color is produced which is destroyed by acids, alcohol, or by heating. Morphine solutions, when mixed with an aqueous solution of potassium ferricyanide containing a drop of ferric chloride T.S., yield deep blue solutions from which, after standing, a blue precipitate separates (difference from *codeine*). Morphine loses not more than 6.5 per cent. of its weight when dried to constant weight at 100° C. (212° F.) (*moisture*). No weighable ash remains on incinerating 0.5 Gm. of Morphine. Dissolve about 0.1 Gm. of Morphine in 10 mils of diluted hydrochloric acid; no red coloration is produced by the addition of a few drops of ferric chloride T.S. (*meconic acid or meconates*). Warm about 0.2 Gm. of Morphine with 4 mils of potassium hydroxide T.S.; the odor of ammonia is not noticeable (*ammonium salts*). Dissolve 1 Gm. of Morphine in 10 mils of sodium hydroxide T.S., shake out the solution with three successive portions of 15, 10, and 10 mils of chloroform, passing the chloroform solutions through a small filter previously moistened with chloroform. Evaporate carefully the combined chloroform solutions to dryness on a water bath, dissolve the residue in 10 mils of fiftieth-normal sulphuric acid V.S., add a few drops of methyl red T.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Not less than 7.5 mils of the latter is required (*foreign alkaloids*)." *U. S.*

Von Gerichten and Schrötter (*Ber. d. Chem. Ges.*, 1882, pp. 1484 and 2179) showed that morphine and codeine were derivatives of phenanthrene, as when distilled with zinc dust they yielded phenanthrene, pyridine, and quinoline. Knorr (*Ber. d. Chem. Ges.*, 22, p. 2081) has shown that it is probable that morphine contains, combined with the phenanthrene nucleus, the *morpholine* group. Morpholine (tetra-hydro-oxazine), $NH<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}>O$, is formed when dioxyethylamine is heated to 160° C. (320° F.) with hydrochloric acid, or is boiled

with alkali. As seen from the formula, it bears a structural relation to both pyrrol and pyridine. For later views on the structure of the morphine molecule by Knorr and Vis, see *Proc. A. Ph. A.*, 1894, 1122. For a chemical bibliography of morphine, by H. E. Brown, see *Ph. Rev.*, 1897, and *Ph. Archiv.*, 1898.

Heated in the open air, morphine burns with a bright flame, and at a red heat is wholly dissipated. In the products resulting from the combustion of opium or morphine this alkaloid may be detected, proving that it is partly volatilized when burned. Morphine in solution is to a considerable extent absorbed by animal charcoal, which, though it will part with most of the alkaloid to alcohol, cannot be wholly deprived of it by repeated washings with that liquid, either cold or hot. It is also absorbed when filtered through kaolin or fuller's earth. (Lefort, *J. P. C.*, Août, 1861, 98.) Its solution restores the blue color of litmus paper reddened by acids, and turns the yellow of turmeric to brown. Hager (*Ph. Ztg.*, 93, 250, also *Proc. A. Ph. A.*, 1893, 680) states that on heating solutions containing morphine, oxygen is absorbed gradually and oxymorphine is formed; at a boiling temperature this change proceeds rapidly. The oxymorphine is much less active as a narcotic than is morphine. This absorption of oxygen takes place most rapidly in alkaline solutions and is also affected by the aid of potassium permanganate, potassium ferricyanide, and ammoniacal copper solution. The reaction is:

$$2C_{17}H_{19}NO_3 + O = (C_{17}H_{18}NO_3)_2O + H_2O$$

This product is known as *oxydimorphine* (or *pseudomorphine*). Morphine is, therefore, a powerful reducing agent, acting upon silver nitrate and gold chloride even in cold solutions. With the acids morphine forms salts, which are generally soluble, and are decomposed by the alkalies. It is dissolved also by the fixed and volatile oils. The solutions of potassium and sodium hydroxides also dissolve morphine, which is precipitated slowly from them on exposure to the air, in consequence of the absorption of carbon dioxide. Solution of ammonia has to a certain extent the same solvent power, and hence the necessity, in precipitating morphine by this alkali, not to employ it in great excess. Solution of iodine with potassium iodide precipitates the salts of morphine in aqueous solution. With chlorine water morphine and its salts assume an orange color, and the same effect is produced on them by solution of chlorinated soda. (Fairthorne *A. J. P.*, xxviii, 9.) By the contact of nitric acid they assume a blood red color, which ultimately changes to yellow, and this is one of the tests of morphine; but, as the same change of color is produced with brucine, it cannot be relied on in the absence of other evidence. Nitric acid also produces a red color with oil of cloves, but in this case the red does not change to yellow. When added to a solution of iodic acid, or an acidulous iodate, morphine and its salts redden the liquid and set iodine free. (Sérullas.) This is a very delicate test, but is not conclusive, as various other organic substances act in a similar manner. J. Lefort, however, has found that the color produced by these substances is removed by ammonia, while the redness produced with morphine is greatly intensified by addition of that alkali. This test, thus modified by the addition of ammonia, is so delicate that, according to Lefort, it will detect one part of morphine in 10,000 parts of a liquid holding it in solution. (*J. P. C.*, Août, 1861, 113.) Husemann's test consists in leaving morphine or its salt in contact with concentrated sulphuric acid for 12 or 15 hours, or in heating for half an hour with the acid to 100° C. (212° F.), and then adding either a little nitric acid, a nitrate or chlorate or chlorine water, or chlorinated soda, when a beautiful bluish or reddish-violet color, passing into deep blood-red and gradually paling, is developed. The presence of small quantities of coloring matter does not prevent this reaction, if chlorinated reagents are selected. A. Husemann asserts that this test will recognize the hundredth part of a milligramme of the alkaloid. (*A. J. P.*, xlvii, 210.) According to R. Schneider, a very delicate test is afforded by putting a drop of the suspected liquid on a plate, saturating with sugar, and putting alongside of it a drop of sulphuric acid; if morphine be present, a very intense purple will be developed at the point of contact, passing after half an hour into violet, then bluish green, and finally dirty yellow. (*J. P. C.*, 4e sér., xviii, 221.) According to H. Weppen, the delicacy of this test is much increased by the addition of a minute quantity of bromine water to the solution. Codeine and aconitine are stated, however, to give the same reaction. (*Ibid.*, 4e sér., xix, 246.)

Fröhde's reagent (a fresh solution of 0.005 Gm. sodium molybdate in 1 mil of pure concentrated sulphuric acid) strikes with morphine and its salts a beautiful blue-violet color, passing into blue then green, finally back to bluish violet. This reaction is stated to be delicate but not characteristic. A. B. Prescott gave a thorough résumé of the views of investigators on this test in *A. J. P.*, 1876, 59. Bruylants combines Fröhde's test with that of Husemann. A trace of Fröhde's reagent added to a solution of morphine in sulphuric acid produces the well-known lilac tint; if the sulphuric acid solution be warmed and treated in the same way, a green tint will be noted. On dropping a particle of potassium nitrate into this green liquid, the color changes to red and finally yellowish. The other opium alkaloids give different tints. (*Proc. A. Ph. A.*, 1895, 1016.) In the presence of sulphuric acid morphine exhibits surprising powers as a reducing agent. Among the most notable instances of deoxidation may be mentioned those of silver oxide, hydrated bismuth oxide, the acids of tin, tungsten, vanadium, titanium, and molybdenum. A solution of titanic acid in con-

centrated sulphuric acid is one of the most delicate reagents for morphine. An intense brown-red to violet color is produced if titanic acid is added to concentrated sulphuric acid containing a trace of morphine in solution. (Flückiger, *N. R.*, Feb., 1880. See also *N. R.*, 1881, p. 237.) M. H. Kahlbrunner states that the most sensitive test is made with a solution (No. 1) of crystallized ferric chloride (thirty grains to four fluidrachms of distilled water) and a fresh solution (No. 2) of potassium ferricyanide (two grains in four drachms). To the suspected liquor five or six drops of No. 1 are added, and afterwards three or four drops of No. 2. If morphine be present, a color varying from deep blue to pale blue and bluish-green, according to the proportion of the alkaloid, is developed. Neither gum, sugar, alcohol, glycerin, atropine, quinine, nor strychnine interferes with this test. An excess of alkali does so by decomposing the ferric chloride. This test depends upon the fact that the potassium ferricyanide solution is reduced by morphine to the ferrocyanide. It is affirmed that even 1-60,000th of one per cent. of morphine can be detected. (See also *Proc. A. Ph. A.*, 1897, 701.) G. Vulpius (*A. Pharm.*, 1887, 25) states that if about 0.00025 Gm. of a morphine salt be dissolved in a porcelain dish in about six drops of concentrated sulphuric acid, a few centigrammes of sodium phosphate added, and the mixture carefully heated, white fumes will be evolved and a violet color appear. On adding water drop by drop, a brilliant red appears, which, on further addition, changes to a dirty green. If the solution be then shaken with the same volume of chloroform, the latter will be colored blue. Isobutylic alcohol has been used by Nagelvoort for the detection of morphine and codeine. (See *Proc. A. Ph. A.*, 1894, 273.)

A delicate reaction for morphine has been reported by T. H. Oliver, which is sensitive to 0.00002 Gm. morphine. It is as follows: To the solution of the suspected substance, add a few mils of hydrogen dioxide solution and a few drops of strong ammonia water. Then stir the solution with a piece of copper wire, whereupon the previously colorless solution becomes of a deep port wine color in the presence of morphine. Codeine and dionine do not give the reaction. (*J. A. M. A.*, 1914, 63, p. 513.)

Siebold heats gently the suspected substance with some drops of concentrated sulphuric acid and a small quantity of chemically pure potassium perchlorate; a deep brown color will be produced if morphine is present. (*P. J.*, Oct., 1873.) According to H. S. Wellcome, one part of morphine in ten thousand parts of water can be recognized by chlorine water, if care be exercised not to decolorize by an excess of the reagent; the color varies from light orange-red to deep red according to the proportion of morphine present. Brucine is the only other alkaloid giving the same reaction, but, while the color produced by morphine is discharged by excess of chlorine, that caused by brucine is not affected. (*A. J. P.*, 1874, p. 305.) Morphine and its salts assume a fine blue color with ferric chloride; at least this is true of the alkaloid, its sulphate, acetate, and oxalate, and the same effect will be produced by the other salts, if previously decomposed by an alkali, but that this test should be satisfactory it is necessary to operate on morphine either in powder or in concentrated solution. (Lefort.) A solution of morphine acetate or sulphate containing only one part of the salt in 100 precipitates silver from a solution of the nitrate of that metal. (Horsley.) Morphine is precipitated from its solutions by potassium or sodium hydroxide, and redissolved by an excess of the alkali. Infusion of galls and other vegetable substances containing tannic acid precipitate morphine in the state of tannate, which is soluble in acetic acid, but according to Dublanc, the alkaloid is not precipitated by pure gallic acid. If ammonia be added to a mixture of the solutions of chlorine and morphine, there will be produced a dark brown color, which will be destroyed by a further addition of chlorine. Sulphuric acid containing a trace of formaldehyde produces a bright purple color with even small traces of morphine. For methods of separating narcotine, see *U. S. D.*, 17th ed., 879.

Formaldehyde reacts with both morphine and codeine to form medicinally active condensation products by the union of two molecules of the base with one molecule of the formaldehyde, with elimination of water; a methylene group, CH_2, uniting with two alkaloidal residues each of which loses an H atom. That formed from morphine is an amorphous base, difficultly soluble in water, but easily soluble in alkaline solution and in alcohol. It melts at 270° C. (518° F.), and forms a hydrochloride soluble in water. (*Proc. A. Ph. A.*, 1897, 702.)

Uses.—There can be no doubt that morphine is the chief narcotic principle of opium, from which, however, it differs somewhat in its mode of action. The effects of morphine are so protean that they can best be considered by taking the different functions of the body seriatim.

Nervous System.—Morphine is a cerebral depressant but a spinal stimulant. The relative predominance of one or the other of these actions depends upon the relative degree of development of the brain or spinal cord; thus in the frog it produces violent convulsions of the strychnic type, but in man the spinal symptoms are usually imperceptible and for medical purposes we may regard it as a general depressant as far as the nervous system is concerned. The primary action upon the cerebrum seems to be a diminution in the powers of perception, especially of pain, although there is often an evident lowering in the acuity of the special senses. With somewhat larger doses intellection becomes depressed and a tendency to drowsiness is manifest, and after toxic doses a deep comatose sleep may follow. The theory that small doses of morphine exercise a primary stimulant influence on intellection we believe is untenable.

When locally applied in sufficient concentration morphine lowers the functional activity of the peripheral nerve endings both motor and sensory. In this way it may, under certain conditions as shown by Wiki (*J. de P. P.*, 1913, xv, p. 848), exercise a local anesthetic action. It is, however, less active in this regard than some of the other allied alkaloids, notably ethyl-morphine or methyl-morphine (codeine). Among the other actions of morphine which are to be attributed to its influence on nerve centers is the contraction of the pupil, due to stimulation of the oculo-motor center, slowing of the pulse from stimulation of the cardio-inhibitory center, slowing of the respiration from depression of the respiratory center, and overcoming the action of nauseants from its action on the emetic center. Cushny and Lieb (*J. P. Ex. T.*, 1915, vi, p. 450) have found that in the period of respiratory depression produced by morphine there is not the same sort of insensibility to carbon dioxide that is caused by some other respiratory depressants, an observation which is of considerable importance in connection with the clinical use of this remedy in dyspneic states.

Circulation.—The action of morphine upon the circulation is quite subsidiary to its effects upon the nervous system. In therapeutic doses the only manifestation of its effects on the part of the circulatory apparatus is slowing of the pulse, due, as mentioned above, to stimulation of the inhibitory center, and flushing of the skin which appears to be the result of a special action on the cutaneous blood vessels. After large doses the blood pressure is generally somewhat lowered, probably from the combined weakening of the heart and vasomotor system.

Nutrition.—Morphine affects the nutrition both through its action upon the digestive processes and through a direct influence on the bodily chemistry. It appears to lessen all the digestive secretions including salivary, gastric, and enteric, also to diminish the peristaltic movements. The direct influence of morphine upon metabolism is not clearly understood, but there is reason to believe that it has some such action.

Elimination.—A large part of the morphine is detoxicated in the body passing out as a dioxymorphine. Some of it, however, is eliminated unchanged, more through the intestinal glands than the kidneys.

Clinical Uses.—Morphine may be used in medicine to fulfil any of seven indications: (1) In its power to relieve *pain* morphine is without rival. Because, however, of its unpleasant action upon the digestive organs and the ever present danger of formation of the habit, it should be reserved for the more severe degrees of suffering, such as in *gall-stone* or *renal colic*, or when other analgesics have failed. In this connection it should be noted that the analgesic action of morphine is greatly enhanced by combining it with even relatively feeble synergists, such as the coal tar series or scopolamine, and by recourse to this principle of combination the physician is often able to assuage the suffering with comparatively small doses of the alkaloid. (2) As a hypnotic morphine is useful, especially when the *insomnia* is due to suffering. In the purely nervous types of sleeplessness it is less valuable than the aliphatic narcotics, but is often of service as an adjuvant. (3) As a sedative to the respiratory center it is a remedy of much value in *asthma* and certain types of *cough*, such as *whooping cough*. In true *bronchitis*, however, it must be used with circumspection. In the acute stage or where the mucous membranes are dry, it often does great harm by a further checking of the bronchial secretions; on the other hand, when the secretions are very profuse it may so benumb the respiratory center as to stop their expectoration and thereby lead to a dangerous retention of fluid in the chest. (4) In intestinal conditions it is used for its influence both on secretion and peristalsis. For the latter action it is of much service in serous *diarrheas*, but when the diarrhea is due to irritation of the intestinal tract it is generally to be avoided, as it defeats nature's purpose to get rid of the irritant. For its influence upon the muscular movements of the bowel it is useful in various forms of intestinal spasm, such as *lead colic*, and also to keep the bowels at rest in certain types of *peritonitis* and other inflammatory conditions. Whole opium is usually preferred to morphine when an action upon the intestines is desired. (5) For the purpose of aiding in the production of diaphoresis it is used, especially in the form of Dover's powder, in the early stages of *colds*, in *rheumatism*, *influenza*, etc. (6) To allay *vomiting*, especially of reflex origin. (7) By its calmative effect it protects the system against exhaustion in debilitated conditions, as certain forms of *typhoid fever*. For the same purpose it is also a very valuable drug in the treatment of *internal hemorrhage*.

In cases where it is desired to make a profound impression upon the general system, morphine should be given hypodermically. The dose varies enormously, according to the susceptibility of the patient and the purpose for which it is used. In a general way the dose of the morphine salts, by mouth, may be given as from one-eighth to one-half grain (0.008-0.032 Gm.), and one-twelfth to one-fourth grain (0.005–0.016 Gm.) hypodermically.

In consequence of its insolubility in water, morphine in its pure state is less convenient than its salts, which are therefore always preferred. The acetate, sulphate, and hydrochloride, which have been employed, act precisely alike therapeutically, and differ from opium chiefly in being less disposed to constipate the bowels. They are also somewhat less likely to cause disagreeable after-effects than is opium, but the deodorized tincture is certainly preferable to them for many purposes. They are further adapted for hypodermic use. Oleic acid has also been proposed as a vehicle for morphine externally used, as it dissolves both the

alkaloid and its salts perfectly in considerable proportion. A liniment of oleate of morphine has been proposed, consisting of 300 parts of oleic acid and 1 part of morphine scented with a little oil of bergamot.

As the proportion of acid necessary to neutralize morphine is very small, the dose of the alkaloid is practically the same as that of its salts.

Dose, one-fifth of a grain (0.012 Gm.), equivalent to a grain of powdered opium.

MORPHINÆ ACETAS. Br.

MORPHINE ACETATE

(mŏr-phĭ'næ ą-cē'tăs)

"Morphine Acetate, $C_{17}H_{19}NO_3,C_2H_4O_2,3H_2O$, is the acetate of an alkaloid, morphine, obtained from opium." *Br.*

Morphiæ Acetas, *Br.* 1867, *U. S.* 1870; Acetate of Morphia; Morphinum Aceticum; Acetas Morphicus; Acétate de Morphine, *Fr.*; Essigsaures Morphium, Morphinacetat, *G.*

A process for this salt is no longer official; that of the U. S. P., 1870, is as follows: "Take of Morphia, in fine powder, *a troyounce;* Distilled Water, *half a pint;* Acetic Acid, *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop Acetic Acid into the mixture, stirring it constantly until the Morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup, and set aside until it concretes. Lastly, dry the salt with a gentle heat, and rub it into powder." *U. S.*, 1870.

In the U. S. process of 1870, morphine is saturated with acetic acid. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is required not to employ too much heat in the evaporation, as the acetate is easily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphine. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals, but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphine in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. Less heat is thus required in the evaporation, and impurities in the morphine may often be detected, as they are likely to be insoluble in alcohol. To ascertain, in this case, whether the morphine is saturated, it is necessary to employ litmus paper, the blue color of which should not be restored if previously reddened by an acid. If the morphine used in preparing the acetate contain narcotine, it will be best to employ diluted acetic acid as the solvent, and to favor its solvent power by heat. Under these circumstances it dissolves only the morphine, leaving the narcotine nearly or quite untouched. (Hodgson, *A. J. P.*, v.) The British process (1885) differs from that of the U. S. Pharmacopœia of 1870 only in obtaining uncombined morphine, as the first step, by precipitating it from a solution of the hydrochloride, morphine itself not being official. As this salt is prone to decompose it is well to prepare it with a slight excess of acetic acid in order to promote its stability.

Properties.—It is officially described in the British Pharmacopœia as "a white, crystalline or amorphous powder. Taste bitter. Almost entirely soluble in 2.5 parts of *water.* Loses acetic acid when exposed to the air. Yields the reactions for morphine described under 'Morphinæ Hydrochloridum,' and the *reactions* characteristic of acetates. 2 grammes form with 5 millilitres of warm *morphinated water* a slightly turbid solution which is rendered clear by the addition of 0.1 millilitre of *acetic acid,* and this solution, when mixed with a slight excess of *solution of ammonia,* yields a white precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' weighs from 1.41 to 1.44 grammes. No appreciable ash." *Br.*

Uses.—This and the other official salts of morphine are of identical medicinal value. The solutions for hypodermic use should be freshly prepared, as morphine salts, especially the acetate, are very prone to undergo decomposition, through the growth of a fungus.

Dose, one-twelfth to one-half grain (0.005–0.032 Gm.).

Off. Prep.—Liquor Morphinæ Acetatis, *Br.*

MORPHINÆ HYDROCHLORIDUM. U. S., Br.

MORPHINE HYDROCHLORIDE Morph. Hydrochl. [Morphinæ Hydrochloras, U. S. 1890, Morphine Hydrochlorate Morphine Chloride]

(mŏr-phĭ'næ hȳ-drǫ-ȼhlō'rī'dŭm)

"The hydrochloride [$C_{17}H_{19}O_3N.HCl + 3H_2O = 375.68$] of the alkaloid morphine. Preserve it in well-closed containers protected from light." *U. S.* "Morphine Hydrochloride, $C_{17}H_{19}NO_3,HCl,3H_2O$, is the hydrochloride of an alkaloid, morphine, obtained from opium." *Br.*

Morphiæ Murias, *Br.* 1867, *U. S.* 1870; Murias (Hydrochloras) Morphicus; Morphiæ Hydrochloras; Muriate of Morphia; Chlorhydrate de Morphine, *Fr. Cod.*; Morphinum Hydrochloricum, *P. G.*; Morphinhydrochlorid, Salzsaures Morphin, *G.*

A process for this salt is no longer official. The British process (1885) will be found in *U. S. D.*, 17th ed., 882. See also *U. S. D.*, 19th ed., 790.

Properties.—This salt crystallizes in "white, silky, glistening needles or cubical masses, or as a white, crystalline powder; odorless; permanent in the air. One Gm. of Morphine Hydrochloride dissolves in 17.5 mils of water and 52 mils of alcohol at 25° C. (77° F.); also in 0.5 mil of boiling water and 46 mils of alcohol at 60° C. (140° F.); soluble in glycerin; insoluble in chloroform or ether. Its aqueous solution (1 in 20) is neutral or slightly acid to litmus. Silver nitrate T.S., when added to an aqueous solution of the salt, produces a white precipitate

insoluble in nitric acid. Add potassium carbonate T.S. to 5 mils of an aqueous solution of the salt (1 in 30), a white precipitate is produced, which does not become green on exposure to air nor yield a color to chloroform when shaken with it (*apomorphine*). Morphine Hydrochloride loses not more than 15 per cent. of its weight when dried to constant weight at 100° C. (212° F.) (*moisture*). In all other respects the salt responds to the tests for identity and purity under *Morphina.*" *U. S.*

"Acicular crystals, or a white microcrystalline powder. Taste bitter. Soluble in 25 parts of *water*. 1 drop of *solution of ammonia* added to 5 millilitres of an aqueous solution (1 in 30) produces a white crystalline precipitate easily soluble in *solution of sodium hydroxide,* but soluble with difficulty in excess of *solution of ammonia;* this precipitate yields mere traces to *benzene* (absence of certain other alkaloids). Yields, when moistened with *nitric acid,* an orange-red color; with *T. Sol. of ferric chloride,* a dull greenish-blue. A trace added to 5 millilitres of a very dilute solution of *potassium ferricyanide* to which 1 drop of *T. Sol. of ferric chloride* has been added produces a deep blue color. 0.1 gramme dissolves in 2 millilitres of *sulphuric acid* without coloration, or with the production of not more than a faint pink color; if a portion of this solution is heated on a water-bath for fifteen minutes, cooled, and treated with a few drops of *diluted nitric acid,* a violet coloration, rapidly changing to blood-red, is produced; the addition of *sodium arsenate* to another portion of the original solution produces a bluish-green color. 1 drop of *solution of potassium carbonate* added to 5 millilitres of an aqueous solution (1 in 30) yields a pure white precipitate which does not become colored on exposure to the air, and does not color *chloroform* when shaken with it (distinction from and absence of apomorphine). When 0.5 millilitre of an aqueous solution (1 in 100) is mixed on a white porcelain tile with 0.5 millilitre of *mucilage of starch* in which 0.005 gramme of *iodic acid* has been dissolved, a blue coloration is immediately produced (distinction from morphine esters). Yields the reactions characteristic of chlorides. 2 grammes dissolved in 50 millilitres of warm *morphinated water* give, on the addition of a slight excess of *solution of ammonia,* a white, crystalline precipitate which, when washed with a little cold *morphinated water* and dried, first at 55° to 60° C. (131°–140° F.), and finally for fifteen minutes at 115° C. (239° F.), weighs from 1.50 to 1.52 grammes. Loses about 14 per cent. of its weight when dried at 100° C. (212° F.). No appreciable ash." *Br.*

A saturated solution in boiling water forms a solid crystalline mass on cooling. The solution of morphine hydrochloride, when kept several months, has been known to produce vomiting, through the formation of traces of apomorphine. (*Ph. Centralh.*, 1885, 93.) Potassium hydroxide throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected by heat, nitric acid, iodic acid, ferric chloride, and chlorine followed by ammonia, in the same manner as morphine. Sugar is said to have been used largely in the adulteration of this salt. It may be detected most readily by the deep red color produced when the adulterated salt is dissolved in strong sulphuric acid. (See *Saccharum.*)

This preparation of morphine is much used in Great Britain, but in this country less than the sulphate. For medicinal properties, see *Morphina.*

Dose, one-twelfth to one-half grain (0.005–0.032 Gm.).

MORPHINÆ SULPHAS. U. S.

MORPHINE SULPHATE Morph. Sulph.

(mör-phī'nē sŭl'phās)

"The sulphate $[(C_{17}H_{19}O_3N)_2.H_2SO_4 + 5H_2O = 758.49]$ of the alkaloid morphine. Preserve it in well-closed containers, protected from light." *U. S.*

Morphiæ Sulphas, *Br.* 1867, *U. S.* 1870; Morphinum Sulphuricum, Sulphas Morphicus; Sulphate of Morphia; Sulfate de Morphine neutre, *Fr. Cod.;* Schwefelsaures Morphium, Morphinsulfat, *G.;* Sulfato morifico, *Sp.*

No process is given in the present U. S. P.; for that of the U. S. P., 1870, see *U. S. Dispensatory,* 19th ed., p. 791. Morphine sulphate is no longer official in the British Pharmacopœia, 1898, the hydrochloride being used in Great Britain, as in Germany, almost exclusively.

In the process of 1870 the morphine is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphine employed contain narcotine, this will remain in the mother liquor, and will not contaminate the product. The mother liquor remaining after the first crystallization may be evaporated so as to afford a fresh supply of the sulphate, but, if the morphine was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further purification. When impure morphine is employed, the mother liquor should be mixed with alcohol, or boiled with purified animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphine; or the mother liquor may be mixed with a little milk of lime, filtered, and precipitated with solution of ammonium chloride, when the morphine will be nearly pure. This may be converted into the sulphate in the manner directed by the U. S. P., 1870.

Another mode of obtaining morphine sulphate is to dissolve the alkaloid in boiling alcohol of 36° Baumé (sp. gr. 0.8428), saturate it

while hot with sulphuric acid, add purified animal charcoal, boil for a few minutes, and filter the solution at the boiling temperature. Upon cooling, it deposits most of the sulphate, and the remainder may be obtained by evaporating the mother liquor. According to J. Calvert (*Pac. Drug.*, June, 1893), morphine sulphate is made as follows: Opium in any quantity is exhausted with water; the resulting liquid is precipitated with an alkaline base and crude morphine is the result. The crude morphine is dissolved in diluted sulphuric acid, solution filtered through animal charcoal and evaporated to a density of 4½° to 5° B. The crystallizing apparatus is a leaden tank, about six inches in depth, of any size to correspond with the amount of morphine sulphate. It is hinged on a frame and has an outlet, with a plug or faucet at the lower end for drainage. The solution being ready and the apparatus adjusted, the hot solution is run into the crystallizer; the solution is stirred gently every few minutes until crystals commence to form on the surface, and then, by carefully stirring, when the solution has come to the right temperature, the morphine sulphate crystallizes suddenly into a solid mass. The mass of crystals is allowed to repose for 48 hours, the plug at the lower end of the tank is removed and the mother liquor is allowed to run off, at first slowly, and afterwards by elevating the tank the last of the liquor is removed; the drainage requires several days. The crystals in the apparatus are then cut up into pieces of the shape of bricks (commencing at the upper end), which are placed on an absorbent, and removed to a drying-room. In ordinary crystallization a certain part of the coloring matter is retained in the crystals. In this case, when the morphine is crystallized as described, and dried in bricks, nearly all the retained coloring matter comes to the surface, so that when the bricks come out of the drying-room the surfaces are brown and in some cases almost black, showing that the coloring matter is eliminated. The next part of the process is to remove the colored part. This is effected by slicing off the dark portions, leaving the morphine sulphate perfectly white. The masses of crystals of morphine sulphate (which have been heretofore described as bricks) are in a condition to be made into a merchantable article. A very sharp knife and delicate handling is used. The bricks are placed on a table and cut into slices each measuring about ¼ inch. These slices are very gently crumbled in the hands or they are preferably cut into cubes or small pieces to distinguish them from other white crystals of a less poisonous nature.

In the evaporation of the solution of this salt, care should be taken not to carry the heat too far, for when pushed to incipient decomposition with an excess of acid, a new substance is formed containing no morphine. This salt is sometimes adulterated. D. B. Dott met with a sample in the English market which contained 34.63 per cent. of anhydrous sodium sulphate. Such an adulteration, however, would be readily detected by the ignition test of the U. S. P. IX. (*P. J.*, August 4, 1877.)

Properties.—It is officially described as in "white, feathery, acicular, silky crystals, or in cubical masses; odorless, permanent in the air. One Gm. of Morphine Sulphate dissolves in 15.5 mils of water and 565 mils of alcohol at 25° C. (77° F.); also in 0.7 mil of water at 80° C. (176° F.), and 240 mils of alcohol at 60° C. (140° F.); insoluble in chloroform or ether. Its aqueous solution (1 in 20) is neutral or slightly acid to litmus. Barium chloride T.S. produces a white precipitate insoluble in hydrochloric acid when added to an aqueous solution of the salt. Morphine Sulphate loses not more than 7.5 per cent. of its weight when dried for four hours at 100° C. (212° F.) (*moisture*). In all other respects the salt responds to the tests for identity and purity under *Morphina*." *U. S.*

By exposure to a heat of 120° C. (248° F.) it loses 9.66 parts of the water, but cannot be deprived of the remainder without decomposition. (Liebig.) The official tests for it are those for sulphuric acid and for morphine. Considerable discussion has taken place in the pharmaceutical journals about the solubility in water of morphine sulphate. Owing to the ease with which the salt parts with its water of crystallization, even at ordinary temperatures, it is not difficult to account for some of the discrepancies that exist in the text-books on this subject. Yet there can be no doubt that the heretofore commonly quoted solubility, "twice its weight of cold water," is an oft-repeated error. J. U. Lloyd (*N. R.*, May, 1882) found it soluble in 21.60 parts of cold water. F. B. Power, after a determination by precipitation with barium chloride, found a commercial specimen of undoubted purity to require very nearly 24 parts of cold water, and the U. S. P., 1880, adopted his results. (*A. J. P.*, 1882, p. 97.) Virgil Coblentz subsequently examined five commercial samples and practically confirmed Power's results, finding the specimens soluble respectively in 21.38, 23.90, 23.18, 17.69, and 18.97 parts of water. D. B. Dott criticizes the methods employed by J. U. Lloyd, and to some extent those of Power, but fails to establish a very different result. (*P. J.*, 1882, p. 252.) The temperature used in obtaining these figures was 15.6° C. (60° F.). The solubility according to the U. S. P. (8th Rev.) is 15.3 parts of water at 25° C. (77° F.).

The *solution of morphine sulphate* formerly official was made by dissolving 1 grain of morphine sulphate in 1 fluidounce of distilled water, and, although the solution is more stable than that of any other of the morphine salts in common use, it will in time become weakened through the presence of microscopic plants belonging to the Confervoideæ, and hence it is not desirable to keep it on hand. According to Hamberg, of Stockholm, the sulphate should be dissolved in boiling distilled water which is free from ammonia, phosphoric, nitric, and nitrous acids; the solution should be filtered through paper not

previously moistened and is best preserved in small well-filled vials closed with a glass stopper. (*Ph. Ztg.*, No. 49; *A. J. P.*, 1881.)

In the United States this salt of morphine is used almost to the exclusion of all others. For medicinal properties, see *Morphina.*

Dose, from one-twelfth to one-half grain (0.005–0.032 Gm.).

MORPHINÆ TARTRAS. Br.

MORPHINE TARTRATE

(mör-phī'næ tăr'trăs)

"Morphine Tartrate, $(C_{17}H_{19}NO_3)_2,C_4H_6O_6, 3H_2O$, is the tartrate of an alkaloid, morphine, obtained from opium." *Br.*

Morphinum Tartaricum; Tartrate de Morphine, *Fr.;* Morphintartrat, Weinsaures Morphium, *G.*

This salt of morphine was brought into notice by Erskine Stuart (1880), and recommended for hypodermic injection because of its greater solubility in water over the other salts of morphine. (See *Injectio Morphinæ Hypodermica,* p. 585, and *Liquor Morphinæ Tartratis,* p. 649.) It is officially described as "minute acicular crystals, efflorescent at 20° C. (68° F.). Taste bitter. Soluble in 11 parts of *water,* forming a clear solution neutral to *litmus.* Yields the reactions for morphine described under 'Morphinæ Hydrochloridum,' and the *reactions* characteristic of tartrates. 2 grammes dissolved in 20 millilitres of warm *morphinated water* give, on the addition of a slight excess of *solution of ammonia,* a precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' weighs from 1.46 to 1.49 grammes. No appreciable ash." *Br.*

A. E. Tanner (*P. J.*, 1903, 134) found morphine tartrate in the English market of low solubility; he investigated the subject and stated that an acid tartrate of morphine was sparingly soluble, that this was found in commerce and that it required 100 parts of cold water for its solution.

Dose, one-twelfth to one-half grain (0.005–0.032 Gm.).

Off. Prep.—Injectio Morphinæ Hypodermica, *Br.;* Liquor Morphinæ Tartratis, *Br.*

MOSCHUS. U. S.

MUSK Mosch. [Tonquin Musk, Deer Musk]

(mŏs'ḉhŭs)

"The dried secretion from the preputial follicles of *Moschus moschiferus* Linné (Fam. *Moschidæ*). Preserve it carefully in glass-stoppered bottles." *U. S.*

Moschus Orientalis, M. Chinensis, M. Tibetanus; Chinese Thibet or Tonquin Musk; Musc, *Fr. Cod.;* Bisam, Moschus, *G.;* Muschio, *It.;* Almizcle, *Sp.*

Musk was deleted from the British Pharmacopœia, 1914.

The *muskdeer* differs from other deer in not having antlers in either sex, and having only one lachrymal orifice, and in the possession of a gall-bladder. The male animal contains in addition the musk-bearing gland to which the animal owes its name. The animal is usually not over 20 inches high with haunches considerably more elevated than the shoulders. From its upper jaw two tusks project downward out of the mouth, each about two inches long, curved backward, and serving to extract the roots which are used as food by the animal. The ears are long and narrow, and the tail very short. The fleece, consisting of strong, elastic, undulated hairs, varies in color with the season, the age of the animal, and perhaps the place which it inhabits. The general color is a deep iron-gray. The musk is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two or three inches long, and from one to two broad, opening by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, thrown into a number of irregular folds, forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old, seldom more than two drachms, and none in the young. According to Frederick Markham, the musk of the younger animals is not so strong as that of the old, but is much pleasanter. (*P. J.*, xv, 472.) The musk is secreted by the lining membrane, and in the living animal forms a consistent mass, which on the outside is compact, and marked with the folds of the membrane, but is less firm towards the center, where there is sometimes a vacant space. As first secreted it is probably liquid, and a portion is occasionally forced out by the animal, to which it communicates its odor. The musk-deer inhabits the mountainous regions of Central Asia, extending from India to Siberia, and from the country of the Turcomans to China. It is an active and timid animal, springing from rock to rock with surprising agility, and frequenting the snowy recesses and most inaccessible crags of the mountains. Concealing itself during the day, it chooses the night for roaming in search of food, and is taken with difficulty. It is hunted for its hide, as well as for the musk. The natives often take it by snaring. As soon as the animal is killed, the sac is cut off, dried, and sent into the market.

Attention has been drawn by E. Bertherand to the excrement of the *Algerian gazelle, Antilope dorcus* L., which possesses a powerful musk-like odor. It is said to contain about 7 per cent. of an acid resin having a musky odor. (*Proc. A. Ph. A.*, xxvi, 332.)

American Musk.—Owing to the costliness of true musk, the sacs derived from *Fiber zibethicus,* the common *musk-rat,* have been used as a substitute. This product possesses many of the

properties of musk, and, although the odor is not identical, it can often replace it in perfumery if used judiciously. If the fatty matter present has become rancid, it should be washed out by agitating the bruised sacs with a little ether and pouring off the ethereal solution, then allowing the musk to become dry by exposure to the air, and carefully preserving the product in sealed packages.

Musk varies in quality with the country inhabited by the animal. That procured from the mountains on the southern borders of Siberia, and brought into the market through Russia, is comparatively feeble. Chinese musk has been said to come from Tonquin, but appears really to be chiefly obtained in Yun-Nan, a province in the extreme south of China, whence it is sent 1400 miles to Shanghai, the export center. A variety intermediate between these is procured in the Himalaya Mountains and Thibet and sent to Calcutta. This is sometimes enclosed in the membranous lining of the sac, without the hairy envelope, and in this condition is said to be quite equal if not superior to that surrounded by the skin, as in the former condition it dries readily in the sun, while in the latter the aid of artificial heat is deemed necessary, by which the musk may sometimes be injured. (F. Peake, *P. J.*, Feb., 1861.) A musk, which is also said to pass from Thibet into China, is known as *Cabardine* musk. (See *C. D.*, 1890.)

Two varieties are known in commerce, the *Chinese, Thibet* or *Tonquin* musk, and *Russian* or *Siberian* musk. Both come in sacs, convex and hairy on one side, flat and destitute of hair on the other. The hairs are brownish-yellow, grayish, or whitish, stiff and short, and arranged concentrically around the orifice of the sac. The Chinese, which is the more highly valued, is in bags of a rounder shape, covered with brownish-yellow or reddish-brown hairs, and containing at most a drachm and a half of large grained, dark, strong scented musk, of an ammoniacal odor. The Russian is in longer and larger bags, small-grained, of a light yellowish-brown color, and of a weaker and more fetid odor, with less odor of ammonia. The annual exportation of musk from Shanghai to New York is about 300 catties, which consists of boxes about 19 cm. in length, 12 cm. wide, and 9 cm. high.

Properties.—Musk is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous color resembling that of dried blood. Some hairs of the pod are generally mixed with it. It is officially described as "usually in small irregular granules, not more than 2 mm. in thickness, blackish with a few brown fragments and becoming somewhat grayish on aging; glistening and somewhat oily; odor peculiar, penetrating, powerful and persistent; taste somewhat bitter. Add a few granules of Musk to 2 mils of water in a watch crystal and stir with a glass rod; a light brown solution is obtained. The undissolved portion consists of irregular fragments containing a finely granular substance, numerous rod-like bacteria and occasionally the hyphæ of a fungus. Add a drop of iodine T.S. to a few granules of Musk on a slide and examine it under the microscope; the particles are not colored blue or bluish-black (*starch*). Add a few granules of Musk to 2 mils of alcohol contained in a watch crystal; the grains sink to the bottom, and upon stirring with a glass rod, a pale brown, slightly cloudy solution is obtained, leaving a somewhat oily stain upon the upper portion of the watch crystal as the alcohol evaporates; the undissolved portion or residue resembles that obtained with the aqueous mixture, except that the particles are less disintegrated. Add a few granules of Musk to 2 mils of chloroform in a watch crystal; the grains float on the surface and upon stirring with a glass rod, the solution remains nearly colorless, and as it evaporates there separates around the particles a small quantity of a whitish, oily or fatty substance. Not less than 50 per cent. of Musk is soluble in water, the solution having a strong, distinctly characteristic odor, and a slightly acid reaction. Not less than 10 per cent. of Musk is soluble in alcohol, the solution being of a light, yellowish-brown color and becoming slightly turbid upon the addition of water. Musk loses not more than 15 per cent. of moisture when dried to constant weight in a desiccator over sulphuric acid. Musk yields not more than 8 per cent. of ash." *U. S.*

The odor is strong, penetrating and so diffusive that one part of musk communicates its odor to more than 3000 parts of inodorous powder. (Fée.) In some delicate individuals it produces headache and other disagreeable symptoms, and it has even caused convulsions. The color of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. Reduced to ashes, it leaves less than 8 per cent. of residue, containing potassium, calcium, magnesia, iron, carbonic, phosphoric, and sulphuric acids, chlorine, and traces of potassium ferrocyanide and ammonium sulphide. (W. Bernatzik.) It yields, upon analysis, a great number of proximate principles. Guibourt and Blondeau obtained water, ammonia, stearin, olein, cholesterin, an oily acid combined with ammonia, volatile oil, ammonium chloride, potassium and calcium chlorides, and unidentified acid combined with ammonia, potassium, and calcium, gelatin, albumin, fibrin, a highly carbonaceous matter soluble in water, a soluble calcareous salt and a combustible acid, calcium carbonate, and phosphate, with hair and sand. (*Ann. Ch. Phys.*, ix, 327.) Besides these constituents, Geiger and Reinman found a peculiar bitter resin, a peculiar substance in part combined with ammonia, and lactic acid both free and in combination. According to Guibourt and Blondeau, it contains 47 per cent. of volatile matter, thought by

some to be chiefly ammonia, by others to be a compound of ammonia and volatile oil. Theimann obtained only from 10 to 15 per cent. But the quantity of volatile as well as of soluble matter varies exceedingly in different specimens. Thus, Theimann found from 80 to 90 per cent. of matter soluble in water, Buchner only 54.5 per cent., and other chemists intermediate proportions. The proportion soluble in alcohol, as ascertained by different experimenters, varies from 25 to 62 per cent. Ether is a good solvent. The aqueous infusion has a yellowish-brown color, a bitterish taste, a strong odor, and an acid reaction. The alcoholic tincture is transparent, and of a reddish-brown color, with the peculiar odor of musk. The action of potassium hydroxide upon musk is accompanied with the extrication of ammonia and an increase of its peculiar odor. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocere, but, according to Guibourt, without diminishing the medicinal activity. The correctness of this opinion, however, is perhaps questionable, and it is advisable to preserve the musk as much as possible unaltered. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change. The odor of musk is very much diminished by mixing it with emulsion or syrup of bitter almond, or with cherry-laurel water. From the experiments of Wimmer, it appears that musk loses its odor when rubbed with golden sulphide of antimony, and reacquires it on the addition of a little solution of ammonia. Camphor rubbed up with musk is also said to destroy its odor. (See *Artificial Musk*, Part II.)

Adulterations.—The price of this medicine is so high, and its sources are so limited, as to offer strong temptations to adulteration, and little genuine unmixed musk is to be found in the market. The sophistication commences in China, and is completed in Europe and this country. A common practice in the East is to open the sac and to supply the place of the musk with an adulterated mixture. Sometimes the scrotum of the animal is filled with this mixture, and not infrequently the sacs are made out of the skin. Dried blood, from its resemblance to musk, is one of the most common adulterations; but, besides this, sand, lead, iron filings, hair, animal membrane, tobacco, the dung of birds, wax, benzoin, storax, asphaltum, artificial musk, and other substances are introduced. These are mixed with a portion of musk, the powerful odor of which is diffused through the mass and renders the discovery of the fraud sometimes difficult. It is said that the Chinese sometimes mix the musk of Tonquin with that of Siberia. The bags containing the drug should have the characters before described as belonging to the natural sac, and should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. When the bag is made from any other portion of the skin, the difference may be detected, according to Neligan, by the microscope. The genuine hairs exhibit innumerable cells, which are wanting in the spurious. (*Chem. Gaz.*, Feb., 1846, p. 79.) Musk which burns with difficulty, has a feeble odor and a color either pale or entirely black, feels gritty to the finger, is very moist so as to lose much weight in drying, or contains obvious impurities, should be rejected. Russian musk is said never to be adulterated before leaving Russia.

For an account of the effects of numerous re, agents on musk, and other modes of identification, as well as of detecting adulterations, see a paper by W. Bernatzik, in *A. J. P.*, 1861, p. 427. There is a discrepancy between Bernatzik's statement of the solubilities of musk and that quoted in the text above. According to the latter, ether is a good solvent; according to the former, ether and chloroform possess scarcely any solvent power. Solubility, however, cannot be relied upon as a test.

Uses.—Musk is stimulant and antispasmodic, in some way stimulating very decidedly the nervous centers when exhausted, without producing either in health or in disease very pronounced symptoms. It is a very valuable remedy in the treatment of nervous exhaustion coming on at or about the crisis of acute disease. When, in low cases of *typhus affections, subsultus tendinum, tremors, singultus,* and similar symptoms indicate the failure of nerve power, its exhibition is often of great advantage. We have seen it apparently save life in the acme of *typhoid fever,* when the vital powers seemed to have almost succumbed, and when violent alterations of temperature or symptoms resembling those of coma vigil had manifested themselves. It was many years ago especially commended by Trousseau in the treatment of *adynamic pneumonia* of drunkards with severe cerebral symptoms. Under these circumstances it certainly appears to do great good. In very obstinate *hiccough* it is one of the most efficient of all of our remedies, and, according to G. B. Wood, it is very effective in those alarming *convulsions of infants* originating in spasm of the intestines. In the *laryngismus stridulus* Bouchut relied mainly on musk, having found it more efficacious than any of the narcotics. (*N. Y. M. J.*, Sept., 1868, p. 545.) According to our experience, musk rapidly loses its power of influencing the nerve centers, and for this reason, and on account of its costliness, its employment should always be delayed until severe nervous exhaustion becomes alarming. It may be given in pill, but is commonly given in emulsion or administered as an enema.

Dose, from five to fifteen grains (0.32–1.0 Gm.).

MUCILAGINES

MUCILAGES

(mū-cĭ-lăg'ĭ-nēs)

Mucilages, *Fr.;* Schleime, *G.;* Mucilagines, *It.*

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopœia, is an aqueous solution of gum, or of substances closely allied to it. In the British Pharmacopœia (1885) the term is applied also to the semi-liquid, jelly-like substance resulting from the cooling of a hot solution of starch.

MUCILAGO ACACIÆ. U. S., Br.

MUCILAGE OF ACACIA Mucil. Acac.

(mū-cĭ-lā'gō ą-cā'cĭ-æ)

Mucilage of Gum Arabic; Mucilage of Gum Acacia; Mucilage de Gomme, *Fr. Cod.;* Mucilage arabique, *Fr.;* Mucilago Gummi Arabici, *P. G.;* Gummischleim, *G.;* Mucilagine di gomma arabica, *It.;* Mucilago de goma arabica, *Sp.*

℞ "Acacia, in small fragments, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Distilled Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Place the acacia in a tared bottle or flask having a capacity not exceeding *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], wash the drug with cold water, allow it to drain, and then add enough warm distilled water to make the mixture weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Securely stopper the container, and agitate it from time to time until the acacia is dissolved. Strain the Mucilage and preserve it in small, well-filled bottles in a refrigerator or in a cool place. Mucilage of Acacia should be frequently made and must not be dispensed if it has become sour or moldy." *U. S.*

"Gum Acacia, 100 *grammes;* Distilled Water, 150 *millilitres.* Rapidly rinse the Gum Acacia with a little *water;* then dissolve it in the Distilled Water in a closed vessel and strain. The Mucilage should be recently prepared. In India and the Eastern Divisions of the Empire, Mucilage of Indian Gum may be employed in making the official preparations for which Mucilage of Gum Acacia is directed to be used (see 'Gummi Indicum')." *Br.*

The gum used for this purpose should be in small fragments or coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum arabic. This mucilage is semi-transparent, almost colorless, if prepared from good gum, viscid, tenacious, of a feeble, peculiar odor, and nearly tasteless. By straining a solution of gum through a layer of freshly precipitated alumina it can be almost entirely decolorized, particularly if the operation be repeated several times. By keeping, the mucilage becomes sour, and this happens even though it be enclosed in well-stoppered bottles; but, according to Guérin, the solution of pure gum undergoes no change *in vacuo.* Heat in its preparation is said to favor the production of acid, and hence cold has been substituted for boiling water in the present formulas. The U. S. P. VIII directed the addition of lime water in making this mucilage; this addition has proved advantageous by neutralizing the acidity generally found in acacia and it promotes stability, but the U. S. P. IX process deleted the lime water. According to R. Rother (*A. J. P.,* xliv, 113), if glycerin be employed in the proportion of one to eight of the mass, and the mixture of water and glycerin be added to the gum in a bottle and solution secured by agitation at intervals over several hours, the resulting mucilage does not spoil; the presence of glycerin is objectionable, however, for many of the uses of mucilage of acacia. E. D. Oesch (*West. Drug.,* 1892, 38) adds about 6 per cent. of alcohol as a preservative. Keller preserves the mucilage by the addition of acetanilid (two grains in the fluidounce). (*C. D.,* 1896, 378.) Archer & Co. have found (*A. J. P.,* xlvi, 469) that if "Tolu water" be substituted for water the mucilage will keep for months. The Tolu water is made by rubbing two drachms of the tincture with magnesium carbonate and two pints of water, and filtering. Mucilage is employed chiefly in the making of pills, and in suspending insoluble substances in water. In prescribing it for mixtures, it should be recollected that it is a solution of definite strength, containing, according to the U. S. formula, half an ounce of the gum to each fluidounce of mucilage. The British mucilage is a little stronger. The adhesiveness of the mucilage is stated to be very much increased by the addition of one part of aluminum sulphate to one hundred and twenty-five parts of the mucilage, but this would not be permissible for a mucilage intended for medicinal purposes.

MUCILAGO GUMMI INDICI. Br.

MUCILAGE OF INDIAN GUM

(mū-cĭ-lā'gō gŭm'mī ĭn'dĭ-cī)

"Indian Gum, 50 *grammes;* Distilled Water, 150 *millilitres.* Rapidly rinse the Indian Gum with a little *water;* then dissolve it in the Distilled Water in a closed vessel and strain. The Mucilage should be recently prepared. In India and the Eastern Divisions of the Empire, Mucilago of Indian Gum may be employed in making the official preparations for which Mucilage of Gum Acacia is directed to be used (see 'Gummi Indicum')." *Br.*

This mucilage was made official in the British Pharmacopœia (1914); it is not as adhesive as the mucilage of acacia.

MUCILAGO TRAGACANTHÆ. U. S., Br.

MUCILAGE OF TRAGACANTH Mucil. Trag.

(mū-cĭ-lā'gō trăg-ą-căn'thæ)

Mucilage de Gomme Adragante, *Fr. Cod.,* Mucilag adragant, *Fr.;* Traganthschleim, *G.;* Mucilagine di gomma adragante, *It.*

℞ "Tragacanth, *six grammes* [or 93 grains]; Glycerin, *eighteen grammes* [or 278 grains];

Water, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the glycerin with *seventy-five mils* [or 2 fluidounces, 257 minims] of water in a tared vessel, heat the mixture to boiling, remove the heat, add the tragacanth, and macerate during twenty-four hours, stirring occasionally. Then add enough water to make the mixture weigh *one hundred grammes* [or 3 ounces av., 231 grains], beat it until of a uniform consistence, and strain it forcibly through muslin." *U. S.*

"Tragacanth, in powder, 1.25 *grammes;* Alcohol (90 per cent.), 2.50 *millilitres;* Distilled Water, sufficient to produce 100.00 *millilitres.* Mix the Tragacanth with the Alcohol; add the Distilled Water as quickly as possible, and shake vigorously." *Br.*

A part only of *tragacanth* is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. The addition of glycerin renders it more serviceable as an excipient. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long, it is apt to undergo decomposition, and to become offensive, but it will keep well if phenol be added. (*A. J. P.,* 1864.) Lyon (*P. J.,* 1901, 600) recommends the use of chloroform water as a preservative in making this mucilage; this is preferred in all cases if the mucilage is not to be used internally. The alcohol in the British process facilitates the quick production of the mucilage, and in addition acts as a preservative.

MYRISTICA. U. S., Br.

MYRISTICA Myrist. [Nutmeg]

(mȳ-rĭs'tĭ-cą)

"The ripe seeds of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*), deprived of the arilli and seed-coats. Preserve the kernels in tightly-closed containers, adding a few drops of carbon tetrachloride or chloroform from time to time to prevent attack by insects. Reject broken or wormy kernels." *U. S.* "Nutmeg is the dried kernel of the seed of Myristica fragrans, *Houtt.*" *Br.*

Muscade, *Fr. Cod.;* Nux Moschata, Noix muscade, *Fr.;* Semen Myristicæ, *P. G.;* Muskatnuss, *G.;* Noce moscata, *It.;* Nuez moscada, *Sp.*

The nutmeg tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves are alternate, petiolate, oblong-oval, pointed, entire, bright green and somewhat glossy on their upper surface, whitish beneath, and of an aromatic taste. The staminate and pistillate flowers are upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish color. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, smooth, at first pale green, but yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the summit, discloses a scarlet reticulated membrane or arillus, commonly called *mace,* closely investing a thin, brown, shining shell, which contains the kernel or *nutmeg.* The nutmeg tree is a native of the Moluccas and other neighboring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs were long derived. But numerous varieties of the plant are now cultivated in Sumatra, Java, Singapore, Penang, Ceylon, and other parts of the East Indies, and have been introduced into the Isles of France and Bourbon, Cayenne, and several of the West India islands. Various species of the genus *Myristica,* other than those which are official, yield commercial seeds or products:

The larger part of the nutmegs of commerce is said still to come from the Dutch Banda Islands. The Penang nutmegs are distinguished by not being limed. The tree is produced from the seed. It does not flower until the eighth or ninth year, after which it bears flowers and fruit together, without intermission, and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the staminate tree is grafted into all the young pistillate plants when about two years old, so as to insure their early fruitfulness. J. H. Hart presented an interesting report (*Bull. Bot. Dept.,* Trinidad, 1907, p. 202) showing that 16-year-old nutmeg trees growing in Trinidad bear both staminate and pistillate flowers. Indeed, he found both kinds of flowers on the same branch of the tree, and he therefore suggests that an attempt should be made to perpetuate this variety by grafting.

In the Moluccas the tree yields three crops annually. The fruit is gathered by hand, and the outside covering rejected. The arillode, constituting the mace of commerce, is then carefully separated, so as to break it as little as possible. It is flattened, dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. The nuts are dried in the sun or by ovens, and exposed to smoke until the kernel rattles in the shell. They are then broken open, and the kernels, having been removed and steeped for a short time in a mixture of lime and water, in order to preserve them from the attacks of worms, are next cleaned, and packed in casks or chests for exportation. Lumsdaine has found them to keep better if rubbed over with dry lime than when prepared in the moist

way. (See *Am. J. Sci.*, Nov., 1851.) Tschirch confirms the value of liming as a preservative against the attacks of insects. (*Ph. Rev.*, 1898, 196.) This is, however, not sufficient protection, as the commercial nutmegs are sometimes "wormy." Nutmegs are brought to this country either directly from the East Indies or indirectly from England and Holland. They are also occasionally imported in small quantities from the West Indies.

The amount of unground nutmegs imported into the United States averages about two million pounds a year.

Properties.—Myristica is officially described as "ovoid or ellipsoidal, from 20 to 30 mm. in length and about 20 mm. in thickness; externally light brown to dark brown, reticulately furrowed, the broad end with a large, circular upraised scar from which arises a furrow extending to the chalaza; easily cut, the surface having a waxy luster and mottled by reason of the light brown perisperm penetrating into the yellowish-brown endosperm; a longitudinal section through the endosperm above the large scar shows a small irregular cavity with the more or less shrunken remains of the embryo, and usually containing a growth of mold; odor and taste agreeably aromatic. The powder is dark reddish-brown; consisting of irregular, yellowish-brown or brownish-black fragments; fragments of perisperm yellowish-brown with large, circular or elliptical oil reservoirs containing a volatile oil, small, thin-walled parenchyma cells, and occasional spiral tracheæ; parenchyma cells of endosperm more or less polygonal and filled with starch grains and aleurone grains; starch grains single or compound, the individual grains being spherical, plano-convex or polygonal, from 0.003 to 0.02 mm. in diameter and colored blue with iodine T.S. (distinction from starch grains in mace, which are colored yellowish-red); mounts in hydrated chloral T.S. show numerous globules of a fixed oil which later may separate in the form of rod-like crystals; mounts in fixed oil show the separation of spheroidal aggregates of crystals which polarize light strongly. The powder made from 'limed' nutmegs show under the microscope, upon the addition of water containing 25 per cent. of sulphuric acid, the immediate separation of crystals of calcium sulphate in the form of small needles or short rods which do not polarize light. Myristica yields not more than 5 per cent. of ash." *U. S.*

"Broadly oval or rounded, rarely more than twenty-five millimetres long; greyish-brown externally, marked with reticulated furrows, and minute black points and lines; internally greyish-red with darker brownish-red veins. Transverse section marbled. Strong aromatic odor; taste aromatic, warm and somewhat bitter." *Br.*

The microscopical structure of nutmeg and mace have been well illustrated by Winton and Moeller in the "*Microscopy of Vegetable Foods.*" Spaeth has recently made an interesting contribution to the pharmacognosy of nutmeg and the detection of the prevalent adulterations in *Ph. Zentralh.*, xlix, p. 627. It has been stated that much of the ground nutmeg of commerce has been made from small, stunted and worthless nutmegs, so-called "grinding nutmegs." The powdered drug is sometimes adulterated with corn meal, powdered beans, curcuma and various nut-shells.

Under the names of *long, female,* or *wild nutmeg, Macassar nutmeg, Papua nutmeg, New Guinea nutmeg, horse nutmeg,* certain seeds have long been known in European commerce; they have finally become an important article of trade, nearly 77,000 kilos of them having been sold in Holland in the year 1894. These seeds have been variously ascribed to *M. fatua* Houtt. (*M. tomentosa* Thumb., *M. macrophylla* Roxb.), and other species of the genus *Myristica,* but by Bassermann and Warburg have in all their varieties been traced to the *M. argentea* Warburg, of New Guinea, from which country they are often taken to Macassar to finally enter commerce as Macassar nutmegs. (*P. J.*, 1898, 97.) The numerous varieties of these false nutmegs are readily reducible to two, which differ chiefly in size, the larger being commonly known as the Papua nuts, the smaller as the Macassar nuts. They are distinguished from the nutmeg by their greater length, their elliptical shape, their comparatively feeble odor and disagreeable taste, and by the absence of the dark brown veins. (Holmes, *P. J.*, lxxxii, p. 459.) Heckel has described two new so-called wild nutmegs from Madagascar. (*Rep. d. Pharm.*, 1909, p. 49.)

Clifford Richardson (*Bulletin U. S. Dept. Agriculture,* No. 13, 1887) gives as the average of three analyses of imported nutmegs: water, 5.56 per cent.; ash, 2.88; volatile oil, 3.23; fixed oil or fat, 34.22; starch, etc., 39.62; crude fiber, 9.21; albuminoids, 5.28; total, 100.00. The volatile oil is obtained by distillation with water. (See *Oleum Myristicæ.*) The virtues of nutmeg are extracted by alcohol and ether.

Nutmegs have been punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their lightness. They are also apt to be injured by worms, which, however, attack preferably the parts least impregnated with the volatile oil. The Dutch were formerly said to heat them in a stove in order to deprive them of the power of germinating and thus prevent the propagation of the tree. The largest nutmegs now command the highest prices. They should be rejected when very light in weight, with a feeble taste and odor, worm eaten, musty, or marked with black veins.

The *concrete* or *expressed oil of nutmeg* (*Oleum Myristicæ Expressum,* Br., 1885), often called *oil of mace,* or *nutmeg butter,* is obtained by bruising nutmegs, exposing them in a bag

to steam, and then compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. Nutmegs are said to yield from 10 to 12 per cent. of this oil, but Flückiger and Hanbury obtained as much as 28 per cent. (See analyses of Richardson, quoted previously.) A process for obtaining it by means of carbon disulphide has been proposed by Lepage, of Gisors, in France, and has received the sanction of the Society of Pharmacy of Paris. It consists in treating the nutmeg, thoroughly comminuted, with three times its weight of the well-rectified liquid referred to, agitating the mixture frequently for 24 hours, expressing, repeating the process with two parts only of the menstruum, mixing the products of the two macerations, filtering in a covered vessel, and then distilling off the disulphide until the residue is entirely deprived of the solvent. (*J. P. C.*, 3e sér., xxxi, 28.) It would seem difficult to prevent the retention of a little of the solvent. The best nutmeg butter is imported from the East Indies in stone jars, or in rectangular blocks 10 inches long by 2½ inches wide, wrapped in palm leaves. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow color, more or less mottled, with the odor and taste of nutmeg. It is composed, according to Schrader, of 52.09 per cent. of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; 43.75 of a white, pulverulent, inodorous substance, insoluble in these liquids; and 4.16 of volatile oil. The pulverulent constituent, which received from Playfair the name of *myristin*, has a silky luster, melts at 31° C. (88° F.), and yields on saponification glycerin and *myristic acid*, $C_{14}H_{28}O_2$. Myristin, $C_3H_5(OC_{14}H_{27}O)_3$, is a true fat, or *glyceryl myristate*. It is also found in spermaceti, in cocoanuts, and in the fixed oil of linseed and poppy oil. It may be obtained directly from nutmeg by exhausting it by means of benzene, filtering the liquid, and allowing it to crystallize by spontaneous evaporation. To purify the product, it may be dissolved in a mixture of two parts of absolute alcohol and three of benzene with the aid of heat, then filtering the liquid while hot, and setting it aside. On cooling, it deposits the pure myristin in crystals. (*J. P. C.*, June, 1859, p. 471.) Analyzed by Koller, the expressed oil was found to contain, in 100 parts, 6 of a volatile oil analogous to the oil of mace, 70 of myristin, 20 of olein, 3 of resin, and 1 of salts, etc. (*A. Pharm.*, clxxiii, 280.) Wallach found in the volatile oil *pinene* and *dipentene* of the class of terpenes and Semmler found *myristicol*, $C_{10}H_{18}O$, which is liquid, and *myristicin*, a solid ester of the composition $C_{12}H_{14}O_3$. An inferior kind of the oil is prepared in Holland, and sometimes found in commerce. It is in hard, shining, square cakes, lighter-colored than that from the East Indies, and with less odor and taste. It is supposed to be derived from nutmegs previously deprived of most of their volatile oil by distillation. An artificial preparation is sometimes sold for the genuine oil. It is made by mixing various fatty matters, such as suet, palm oil, spermaceti, wax, etc., adding some coloring substance, and giving flavor to the mixture by the volatile oil.

Ucuhula nut is a round or oval seed of *Myristica surinamensis*. It is one-half to two-thirds of an inch in diameter, light brown, but usually covered by a blackish, thin, friable testa. Internally it resembles the nutmeg, but is distinguished by the presence of extraordinarily large and handsome albuminous crystalloids. These seeds are said to contain over 70 per cent. of a solid yellow fat, melting at 36° C. (96.8° F.). (See *A. J. P.*, 1886; also *A. Pharm.*, July, 1888.) The kernel of the fruit of the Brazilian *Myristica officinalis* Mart. (*M. Bicuhyba* Schott), resembles the nutmeg in form and structure, but is covered with a black shell marked with broad furrows. It contains crystals like those above spoken of, but less splendid and regular, and apt to be in three forms. It yields a fat (*bicuhyba fat*, or *bicuhyba balsam*) very much like that of the ordinary nutmeg, but having a rather sour, sharp taste, melting at 47° C. (116.6° F.). It contains a peculiar fatty acid, *bicuhybastearic* acid. The *otoba fat* is the product of the fruit of *Myristica Otoba*. It is almost colorless, when fresh has a nutmeg-like odor, melts at 38° C. (100.4° F.), and contains *myristin*, *olein*, and *otobite*. The latter principle crystallizes in shiny, colorless crystals, melting at 133° C. (271.4° F.). The fruit of *Virola sebifera* Aubl. (*s. Myristica sebifera* Lam.), also yields a fatty substance which is known as *ocuba wax*. The so-called *California nutmeg* is not a nutmeg at all, but the seed of a coniferous tree, *Torreya californica*. It is oblong, with a smooth, brownish, thin testa, and affords a marbled cross-section. Its odor and taste are terebinthinate. Neither are the *Jamaica* or *calabash nutmeg*, from *Monodora Myristica*, the *New Holland* or *plume nutmeg*, from *Atherosperma moschata*, and the *clove nutmeg*, from *Agathophyllum aromaticum*, true nutmegs.

Uses.—Nutmeg owes its medicinal and toxic properties solely to the volatile oil which it contains. For the consideration of the effects and uses of this, see page 777. Powdered nutmeg is rarely used in medicine alone, although it enters into the composition of a number of galenicals. The expressed oil is occasionally used as a gentle external stimulant and was an ingredient in the *Emplastrum Picis* of the 1885 British Pharmacopœia. *Mace* possesses properties essentially the same as those of nutmeg.

Dose, five to twenty grains (0.32–1.3 Gm.).

MYROBALANUM. Br.

MYROBALANS

(mȳ-rō-bă-lā'nŭm)

"Myrobalans are the dried immature fruits of Terminalia Chebula, *Retz.*, usually distinguished in commerce as Chebulic myrobalans." *Br.*

Five varieties of these East India fruits are distinguished by authors. The most important are as follows: (1) *Myrobalani Chebulæ.* This is the only variety which is official. It is produced by the *Terminalia Chebula* Retz (*Buceras Chebula*). This by some is believed to be identical with the *T. Bellerica* noted below. The fruit is roundish or ovate, varying in size from that of a hazel nut to that of a walnut. It consists of an exterior firm fleshy portion and an interior kernel which is light brown, inodorous and with a bitterish, astringent taste.

(2) *Myrobalani Bellericæ.* This is obtained from the *T. Bellerica* Roxb. It closely resembles the previous variety but is of a more grayish brown color and is sometimes supplied with a short thick foot stalk which is lacking in the official form.

(3) *Myrobalani citrinæ* vel *flava.* These are from a variety of the same tree which affords the chebula myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish color, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of *white galls,* to which, however, they bear no other resemblance than in taste.

(4) *Myrobalani indicæ* vel *nigræ.* These are thought to be the unripe fruit of *T. Buceras* (*Bucida Buceras*). They are ovate-oblong, from four to eight lines long and from two to three lines thick, of a blackish color, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the center. They are sourish and very astringent.

(5) *Myrobalani emblicæ.* This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliæ, of the fam. *Combretaceæ*—namely, the *Phyllanthus Emblica* L. (fam. *Euphorbiaceæ*).

Myrobalans are officially described in the Br. Pharm., 1914, as "irregularly ovoid or fusiform, from ten to thirty millimetres or more long and from five to fifteen millimetres wide; strongly shrivelled longitudinally, dark brown or nearly black; in transverse section dark, with a small central cavity; hard. No odor; taste very astringent." *Br.*

When the fruit is entire, it is blackish, spherical depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste. It is often in segments, as found in commerce. These fruits contain about 40 per cent. of tannin which is identical with gallotannic acid. They have occasionally been used for the commercial manufacture of tannin. The resulting product is less pure, however, than that from nut galls.

Uses.—Myrobalans were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly *diarrhea* and *dysentery.* Pierre Apery states that when roasted they are still used in Turkey with excellent results in *intestinal* catarrhs. (*R. T.,* Dec., 1887.) Although the myrobalans are of various origin, they all probably depend for their physiological activity upon the presence of gallotannic acid. Procter states that they contain from 30 to 35 per cent. of gallotannic and ellagitannic acids.

The ointment is used as a local astringent.

The internal *dose* of myrobalans is one-half to one drachm (2.0–3.9 Gm.), given in the form of a powder.

MYRRHA. U. S., Br.

MYRRH Myrrh. [Gum Myrrh]

(mȳr'rhą)

"A gum-resin obtained from one or more species of *Commiphora* (Fam. *Burseraceæ*)." *U. S.* "Myrrh is an oleo-gum-resin obtained from the stem of Commiphora Myrrha, *Holmes,* and probably other species." *Br.*

Arabian or Somali Myrrh, Herabol Myrrh; Gummi Resina Myrrha; Myrrhe, *Fr. Cod.;* Myrrha, *P. G.;* Myrrhe, *G.;* Mirra, *It., Sp.;* Murr, *Ar.;* Bowl, *Hindost.*

Though *myrrh* has been employed from the earliest times, it is still uncertain by what plant it is yielded. The *Amyris Kataf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient proof. Afterwards Ehrenberg met on the frontiers of Arabia Felix with a plant from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From the specimens of the plant taken by Ehrenberg to Germany, Nees von Esenbeck referred it to the genus *Balsamodendron* of Kunth, and named it *Balsamodendron Myrrha.* It was not thought by De Candolle sufficiently distinct, but is now generally recognized under the name of *Commiphora,* first given it by Jacquin in 1797, and therefore preceding the name of Kunth by some 27 years. Berg found another species in Ehrenberg's collection, to which was attached a label by the discoverer, stating that he had collected myrrh from it, and proposed to call it *Balsamodendron ehrenbergianum.* (*A. J. P.,* 1873, 314.) Both Oliver and Trimen agree that this plant is not specifically distinct from *B. Opobalsamum.* It is probable that there are gum resins from several species of the *Commiphora* which furnish commercial myrrh. Hildebrand (*P. J.,* 1878, ix, p. 893) collected the *C. Myrrha* on the north Somali

coast in 1873, and presents evidence to show that it yields myrrh. Although this view has been disputed, E. M. Holmes (*Y. P. B.,* 1913, p. 453) supports it and this species is recognized by the British Pharmacopœia. Defiers and Schweinfurth (*Ber. d. Pharm Ges. zu Berlin,* 1893), however, believe that genuine myrrh is yielded by *Commiphora abyssinica* (Berg.) Engl., which is found in Southern Arabia, Erithrea, and Northern Abyssinia. *C. Schimperi* (Berg.) Engl., occurring in the Yemen, Abyssinia, and from Kern to Tigré, is likely also to yield some of the commercial Arabian myrrh. It appears to be established that *C. Myrrha* produces *myrrh,* but it is probable that it is also yielded by other trees belonging to the genus *Commiphora,* which genus includes more than 60 species, natives of Arabia and Africa.

Commiphora Myrrha (Nees) Engler (Syn. *C. Myrrha* Holmes) is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two latter are much smaller than the one at the end. The fruit is oval-lanceolate, pointed, longitudinally furrowed, of a brown color, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighborhood of Gison, in dwarfish thickets, interspersed among the *Acaciæ* and *Euphorbiæ.* The juice concretes spontaneously upon the bark.

Formerly the best myrrh was brought from the shores of the Red Sea by way of Egypt and the Levant, and hence received the name of *Turkey myrrh,* while the inferior qualities were imported from the East Indies, and were commonly called *India myrrh.* These titles have ceased to be applicable, as myrrh of all qualities is now brought from the East Indies, whither it is carried from Arabia and the northeastern coast of Africa. Aden in the former region, and Berbera in the latter, would appear, from the statements of James Vaughan, to be the chief entrepôts of the trade. (*P. J.,* xii, 226.) It is usually imported in chests containing between one and two hundred-weight. Sometimes the different qualities are brought separate, but oftener more or less mingled. Only the best kind should be selected for medicinal use.

There are several varieties of myrrh recognized in commerce. The official description corresponds to that of that known as the Arabian myrrh or Somalian myrrh.

Another variety of myrrh coming from Arabia known as the *Fahdi myrrh* is described in the *Pharmacographia* as "occurring in irregular masses, seldom exceeding 1½ inches long, and having a somewhat gummy-looking exterior. The larger lumps seem formed by the cohesion of small, rounded, translucent, externally shining drops or tears. The fracture is like that of common myrrh, but less unctuous, and has not the whitish markings. The odor and taste are those of the ordinary drug." This myrrh is said to be collected on the hills about Shugraeea and Sureeae, east of Aden. "*Meetiya,*" or *Arabian Myrrh of Dymock,* is said to be sold in India as true myrrh. It has a dull surface, a dark reddish-brown color, a more unctuous and waxy fracture, and has white marks like Somali myrrh, which it resembles in taste, but its odor is rather less fragrant. *Yemen Myrrh,* which is said by Hanbury to contain a resin which differs from that of Somali myrrh and the Arabian myrrh or Fahdi in that its solution in petroleum spirit does not give a violet color on the addition of bromine. This myrrh is said to enter commerce chiefly from Makulla via Aden and Bombay. It occurs in large pieces 1 to 3 inches long, irregularly rounded and characterized by a dark reddish-brown color with a similarly colored fracture free from whites streaks. Odor and taste similar to Somali myrrh, but stronger and more rank.

Mecca balsam, according to G. Schweinfurth, is yielded by *Commiphora Opobalsamum,* from which it is collected in the valleys near Mecca. It is said to be the myrrh of the Bible, the error of translation having been made on account of the similarity of the old Hebrew word "mar" with the modern Arabic word "morr," the name of the true myrrh.

Properties.—Myrrh is "in rounded or irregular tears or masses, brownish-yellow or reddish-brown, and covered with a brownish-yellow dust; fracture waxy, somewhat splintery, translucent on the edges, sometimes marked with nearly white lines; odor balsamic; taste aromatic; bitter and acrid. The powder is yellowish-brown; 0.001 Gm. of the powder, when added to a drop of fixed oil on a slide and examined under the microscope, shows numerous angular fragments varying in color from pale yellow to yellowish-brown; when mounted in hydrated chloral T.S. the color of the yellowish fragments is intensified; the addition of iodine T.S. to the powder, previously mounted in hydrated chloral T.S., may show the presence of a few starch grains varying in shape from spherical, polygonal, and narrowly ellipsoidal to somewhat pear-shaped, from 0.01 to 0.035 mm. in diameter; when mounted in phloroglucinol T.S. and hydrochloric acid the powder may show a few fragments of lignified tissues consisting of either sclerenchymatous fibers, or of small groups of stone cells, the individual cells of the latter with very thick, porous walls and from 0.015 to 0.05 mm. in length. Not less than 35 per cent. of Myrrh is soluble in alcohol. Myrrh yields not more than 8.5 per cent. of ash." *U. S.*

"In rounded or irregular tears, or masses of agglutinated tears, varying much in size; reddish-brown or reddish-yellow externally, dry, and more or less covered by a fine powder; brittle, the fractured surface irregular, somewhat translucent, of a rich brown color, oily, and frequently exhibiting whitish marks. Aromatic odor; taste aromatic, bitter and acrid. Not more than 70 per cent. insoluble in *alcohol* (90

per cent.). The solution obtained by boiling 0.1 gramme of coarsely powdered Myrrh with 2 millilitres of *alcohol* (90 per cent.), evaporated in a porcelain dish so as to leave a thin film, yields a residue which assumes a violet color in contact with *nitric acid* diluted with an equal volume of *water*. Ash not more than 5 per cent." *Br.*

Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously, and is not fusible by heat. Its sp. gr. is stated as 1.36. The inferior kind is in pieces much darker, more opaque, less odorous, and often abounding with impurities. We have seen pieces of India myrrh enclosing large crystals of sodium chloride, as if the juice had fallen from the tree and concreted upon the ground where this mineral abounds. Pieces of *bdellium*, and other gummy or resinous substances of unknown origin, are often mixed with it. Among these is a product which may be called *false myrrh*. It is in irregular pieces, of a dirty reddish-brown color, a vitreous brownish-yellow fracture, semi-transparent, of a faint odor of myrrh, and a bitter balsamic taste. Myrrh is best purchased in mass, as in powder it is liable to adulterations not easily detected. It is sometimes admixed with small stones which are added when the myrrh is in a moist state. Much of the commercial article is contaminated with the so-called Somali myrrh which does not meet the Pharmacopœia requirements. It is also adulterated with senegal gum and chestnuts.

George F. Merson (*P. J.*, Jan., 1900, 42) proposes as a test of the quality of myrrh that it should yield not more than 5 per cent. of ash, which should be almost entirely soluble in diluted hydrochloric acid, and that when exhausted with 90 per cent. alcohol and dried at 100° C. (212° F.) one gramme should not afford more than 0.6 Gm. of residue.

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odor and taste. By distillation a volatile oil rises, having the peculiar flavor of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in solutions of the alkalies, and, when triturated with them in a crystalline state, forms a tenacious liquid. Hence potassium carbonate may be used to facilitate its suspension in water. Hirschsohn recommends as a reagent for myrrh, trichlor-acetal-chloroform, which is obtained by conducting chlorine into seventy-five per cent. alcohol until turbidity ensues and two layers are formed; the lower of these is shaken with an equal volume of water and then with calcined magnesia and filtered. In one part by weight of the trichloracetal thus obtained, four parts by weight of hydrated chloral are dissolved by heating. The syrupy reagent thus made, which fumes slightly in the air, gives a violet color with the smallest quantity of pure Herabol myrrh. Hirschsohn failed to get a similar reaction with any other resin, not even with Bisabol myrrh. (*Ph. Centralh.*, 1903, 809.) An analysis by Ruickoldt gave 2.183 per cent. of volatile oil, 44.760 of resin, 40.818 of gum or arabin, 1.475 of water, and 3.650 of calcium and magnesium carbonate, with some gypsum and ferric oxide. The volatile oil has been called *myrrhol* or *myrrhenol*, and, according to Ruickoldt, has the formula $C_{10}H_{14}O$. Koehler (*A. J. P.*, 1890, p. 346) confirms this formula, and states that this body, while isomeric with thymol and carvol, is distinct from them. He found 7 or 8 per cent. of essential oil, instead of 2.18 as previously given. Gladstone (*J. Chem. S.* [2], 2, 1) found that the oil had a sp. gr. of 1.0189 at 7.5° C. (45.5° F.), a boiling point of 266° C. (510.8° F.), and was lævorotatory. The resin, which he calls *myrrhin*, $C_{45}H_{32}O_{10}$, is neutral, but becomes acid when kept for a short time in fusion. In the latter state Ruickoldt proposes to call it *myrrhic acid*. (*A. Pharm.*, lxi, 1.) Koehler has found in the portion soluble in alcohol an indifferent soft resin, to which he gave the formula $C_{26}H_{34}O_5$, containing three replaceable OH groups, and two dibasic resin acids, of the formulas $C_{26}H_{32}O_{16}$ and $C_{26}H_{32}O_9$. An investigation of the essential oil of Bisabol myrrh from the interior of the Somali country was made by W. Tucholka. (*Schim. Rep.*, Oct., 1897, 36.) He obtained by distillation 7.8 per cent. of an oil of 0.8836 sp. gr., boiling at from 220° to 270° C. 428°–518° F.). From this was separated, by means of the crystalline hydrochloride, a terpene boiling at from 259° to 260.2° C. (498.2°–500.36° F.), which the author calls *bisabolene*, and an oxygenated portion to which he gives the rather strange formula $C_{56}H_{96}O$. According to Bley and Diesel, myrrh containing a little volatile oil always has an acid reaction, which they ascribe to the oxidation of the oil. They also found formic acid in the specimen examined by them. The same investigators propose as a test of myrrh the production of a transparent dirty-yellow liquid with nitric acid, while false myrrh affords a bright-yellow solution in the same fluid, and bdellium is not dissolved, but becomes whitish and opaque. (*A. J. P.*, xviii, 228.) According to Righini, if powdered myrrh, rubbed for fifteen minutes with an equal weight of ammonium chloride, and fifteen times its weight of water gradually added dissolves quickly and entirely, it may be considered pure. Chas. E. Escott (*A. J. P.*, 1887) extracted a sample of myrrh with petroleum benzin, and on spontaneous evaporation of the solvent obtained 18.75 per cent. of oily residue. The gum left after treatment with alcohol had a barely perceptible odor of myrrh and a slightly mucilaginous taste, was neutral to test paper, and, though of a pale color, gave with water a dark-brown solution. The insoluble portion amounted

to 15 per cent., or 8.4 per cent. of the weight of the myrrh. The diluted solution acquired a purple color by ferric chloride, changed to reddish-yellow by ammonia. Stronger solutions were precipitated by alcohol, not gelatinized by borax, and the precipitate with lead subacetate was not redissolved. The gum makes a good mucilage, and, when making tincture of myrrh, the residue insoluble in the alcoholic menstruum should be saved for that purpose.

Uses.—Myrrh is a stimulant tonic, with some tendency to the lungs, and perhaps to the uterus. It is also employed as a tonic in *dyspepsia,* and as an expectorant and emmenagogue in *debilitated states* of the system, in the absence of febrile excitement or acute inflammation. The diseases in which it is usually administered are *chronic catarrh, phthisis pulmonalis,* other *pectoral affections* in which the secretion of mucus is abundant but not easily expectorated, *chlorosis, amenorrhea,* and the various affections connected with this state of the uterine function. It is generally given combined with chalybeates or other tonics, and in *amenorrhea* very frequently with aloes. It is used also as an application to *spongy gums,* the *aphthous sore mouth* of children, and various kinds of *unhealthy ulcers.*

A *plaster of myrrh* is made by rubbing together powdered myrrh, camphor, and balsam of Peru, of each an ounce and a half, then adding the mixture to 32 ounces of lead plaster previously melted, and stirring well until the plaster thickens on cooling. It is then to be formed into rolls. This plaster may be employed in all cases where a gentle and long-continued rubefacient effect is desired.

Myrrh may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Griffith. (*Mistura Ferri Composita.*) The infusion is also sometimes given, and an aqueous extract has been recommended as milder than myrrh in substance. The tincture is used chiefly as a local application.

Dose, ten to thirty grains (0.65–2 Gm.).

NITROGENII MONOXIDUM. U. S.

NITROGEN MONOXIDE Nitrogen. Monox. [Nitrous Oxide]

(nī-trō-gĕn'ī-ī mō-nŏx'ĭ-dŭm)

"Nitrogen Monoxide gas [$N_2O = 44.02$]." *U. S.*

Laughing gas; Oxyde nitreux, Potoxide d'Azote, *Fr.;* Stickstoffoxydul, Lachgas, *G.*

These names were originally given to a gaseous substance, discovered by Priestley in 1776, but first brought into general notice in 1800 by Humphry Davy, who discovered and made known the remarkable exhilarating properties which earned for it the name of laughing gas.

Preparation.—In its preparation, pure fused ammonium nitrate is submitted in a glass retort to a heat sufficient to decompose it, not exceeding 204.4° C. (400° F.), and the resulting gas and vapor are collected in a glass receiver over warm water or a saturated aqueous solution of common salt. Warm water is preferred because cold water absorbs much of the gas, and would consequently occasion loss, and even warm water, though it takes up much less, is not entirely unobjectionable on this score; the saline solution is therefore probably, on the whole, best adapted to the purpose. When ammonium nitrate is heated to the point of decomposition, it is wholly resolved into aqueous vapor and nitrogen monoxide, according to the reaction:

$$NH_4.NO_3 = 2H_2O + N_2O$$

But it is necessary not to let the heat employed in the process be too high, as otherwise, besides nitrous oxide, there will come over portions of nitric oxide, uncombined ammonia, and probably even nitric acid, which contaminate the product, and render it unfit for use. This may be avoided by arresting the process as soon as any white fumes appear in the retort. Peculiar care also must be taken that the ammonium nitrate should be pure, and especially free from ammonium chloride, which might cause an admixture of chlorine in the product. To insure against impurities of this kind, it is best in any case in the least doubtful, and perhaps it might be best in all cases, to cause the nitrous oxide, before it is used by inhalation, to pass successively through two solutions: one, of ferrous sulphate, to remove any nitric oxide that might be present; the second, of potassium or sodium hydroxide, to neutralize acid impurities and chlorine. At times nitrogen gas is also found in the nitrogen monoxide, probably resulting from a trace of nitrite present or some reducing action upon the nitrate in the moment of its decomposition. When the monoxide is liquefied under pressure this free nitrogen remains as unliquefied gas.

Among the impurities sometimes found in commercial specimens of NO are free ammonia or free nitric acid, which, under ordinary circumstances should recombine to form ammonium nitrate. If, however, the apparatus is metallic, the nitric acid may combine with the metal to form a nitrate and the corresponding amount of ammonia cannot recombine with acid and is thus left free as a dangerous impurity.

Nitrogen monoxide gas is colorless, inodorous, slightly sweetish to the taste, and of the sp. gr. 1.527 compared with air. Cold water will absorb about three-fourths of its bulk of the gas,

and, under pressure, much more, and, thus impregnated, has a slight, not unpleasant odor, and a sweetish taste. By the joint influence of cold and pressure the gas may be condensed into a liquid, which is colorless, very mobile, and capable, under the ordinary atmospheric pressure, of remaining liquid at –12.7° C. (9° F.). The liquefaction was effected by Bianchi at 0° C. (32° F.), under a pressure of thirty atmospheres. (*A. J. P.*, 1865, 275.) Inflammable bodies will generally burn with increased vigor in nitrous oxide, but it is entirely incapable of giving oxygen to the blood.

It is officially described as "a colorless gas possessing a slight characteristic odor and a somewhat sweet taste. It supports the combustion of many substances. For convenience in handling and use, it is compressed in metal cylinders. It is quite soluble in water at low temperatures; 1 volume of water dissolves about 1.3 volumes of nitrous oxide at 25° C. (77° F.). Pass 2000 mils of the gas, measured under normal atmospheric pressure at about 25° C. (77° F.), through 100 mils of barium hydroxide T.S. at a rate not exceeding 4000 mils per hour; not more than a slight turbidity is produced (*carbon dioxide*). No opalescence is produced in a mixture of 100 mils of distilled water and 1 mil of silver nitrate T.S. by 2000 mils of the gas under the conditions described above (*halogens*). No change in color is produced in 100 mils of distilled water to which 5 drops of litmus T.S. have been added, by the passage of 1000 mils of the gas through the liquid under the conditions described above (*acids or bases*). No alteration in color is produced in a solution of 0.2 mil of tenth-normal potassium permanganate V.S. in 100 mils of distilled water, by the passage of 1000 mils of the gas through the liquid under the conditions described above (*reducing substances*)." *U. S.*

Uses.—Although Sir Humphry Davy as far back as 1800 suggested the use of nitrous oxide for the production of anesthesia, the first practical employment of it was in 1844 by Horace Wells, of Connecticut. Nitrous oxide is remarkable among anesthetics in being almost physiologically inert, save in its effect on the cerebrum. While as it is ordinarily administered there are marked alterations in the circulation owing to partial asphyxia, by carefully combining pure oxygen with the gas it is possible to induce with nitrous oxide a state of complete anesthesia without any considerable change in either the rapidity of the pulse, the blood pressure, or the respiration. It differs also from the liquid anesthetics in that it is not depressant to the spinal cord. For operations of short duration, such as extraction of teeth, opening of abscesses, and the like, it should always be the anesthetic of preference if available. The mortality in this group of operations is almost nil; it has been estimated variously as from one death in a hundred thousand to one in a million. The two great drawbacks to its more frequent employment are its cumbersomeness of transportation and the shortness of the narcosis. By administering it in conjunction with pure oxygen the inhalation may be continued for long periods of time, so that it can be employed in major operations. There is, however, great difference of opinion as to the advisability of its use for this purpose; Crile (*J. A. M. A.*, 1910, liv), who has had a large experience with it, believes that with a skilful anesthetist it is safer than ether, but that in the hands of the inexperienced is more dangerous.

NUX VOMICA. U. S., Br.

NUX VOMICA Nux Vom. [Strychni semen, P. I.]

(nŭx vŏm'ĭ-cą)

"The dried, ripe seeds of *Strychnos Nux-vomica* Linné (Fam. *Loganiaceæ*), yielding not less than 2.5 per cent. of the alkaloids of Nux Vomica." *U. S.* "Nux Vomica consists of the dried ripe seeds of Strychnos Nux-vomica, *Linn.*" *Br.*

Semen Nucis Vomicæ; Poison Nut, Quaker Buttons, Dog Buttons; Noix vomique, *Fr. Cod.*; Semen Strychni, *P. G.*; Krähenaugen, Brechnuss, *G.*; Noce vomica, *It.*; Nuez vomica, *Sp.*

Strychnos Nux-vomica is a tree of a moderate size, with numerous strong branches, covered with a smooth, dark gray bark. The young branches are long, flexuous, smooth, and dark green, with opposite, roundish-oval, petiolate, entire, smooth, and shining leaves. The flowers are small, white, funnel-shaped and in terminal corymbs. The fruit is a round berry, about as large as an orange, with a smooth, yellow or orange-colored, hard, fragile rind, and many seeds in a juicy pulp. It has frequently been asserted that the pulp is innocuous, but Flückiger and Hanbury, and also Dunstan and Short (*P. J.*, 3d series, xv, 1) have demonstrated that it contains strychnine. Dunstan and Short have also proved that of the commercial varieties of nux vomica Bombay seed stands first in percentage of contained strychnine, then Cochin, and lastly Madras. (*P. J.*, 1883, xiv, 1053.)

The tree is a native of the East Indies, growing in Bengal, Malabar, on the Coromandel Coast, in Ceylon, in many islands of the Indian Archipelago, in Cochin China, and in Northern Australia. The drug is largely shipped from Madras, where it is estimated that in 1912 nearly 400,000 pounds were marketed. Much of the nux vomica shipped to the United States is exported from Bombay, and in 1910–1911 some 45,000 pounds of nux vomica were exported to the United States from the Bombay district. The chief markets for nux vomica are China, and America, small quantities are shipped to London, and the importations to Hamburg are very irregular. Joblin states that during the fiscal year 1909 there were imported into the United States 1,666,957 pounds of nux vomica; in 1910, 2,738,662 pounds. (*Cons. & Tr. Rep.*, 1911, p. 350.)

The wood and root are very bitter, and are employed in the East Indies for the cure of

intermittents. The *radices colubrinæ* and *lignum colubrinum* of the older writers, long known in Europe as narcotic poisons, have been ascribed to this species of *Strychnos,* under the impression that they were identical with *Strychnos colubrina,* to which Linnæus refers them. They were ascertained by Pelletier and Caventou's researches to contain a large quantity of strychnine. The bark has been mistaken for cusparia, and hence is sometimes referred to as *false angustura.* Gehe & Co. (*Handelsbericht,* 1914, p. 119) state that a new variety of nux vomica, the origin of which is unknown, is being exported from Burma. The seeds are externally light gray, internally yellow and are devoid of strychnine.

Properties.—Nux vomica is officially described as "orbicular, nearly flat, occasionally irregularly bent, from 10 to 30 mm. in diameter and from 4 to 5 mm. in thickness, very hard when dry; externally grayish or greenish-gray, covered with appressed hairs giving it a silky luster, hilum indicated by a circular scar at the center of one of the flattened sides and connected with the micropyle at the edge by a ridge; internally showing a thin, hairy seed-coat and a large grayish-white endosperm at one end of which is embedded a small embryo with two broadly ovate, 5- to 7-nerved cotyledons; inodorous; taste intensely and persistently bitter. The powder is light gray; consisting chiefly of thick-walled endosperm cells containing globules of a fixed oil and a few small aleurone grains, and fragments of strongly lignified, non-glandular hairs, the walls of the latter possessing large, circular, or long, slit-like pores. In the tissues of the adhering pulp occur a few small, nearly spherical starch grains. Nux Vomica yields not more than 3.5 per cent. of ash." *U. S.*

"Seeds disc-shaped, nearly flat, but sometimes irregularly bent; rounded or somewhat acute at the margin, from a small prominence on which a raised line passes to the central hilum. Ash-grey or greenish-grey. From two to two and a half centimetres in diameter, and about six millimetres thick. Surface densely covered with short, satiny, radiately arranged and closely appressed hairs. Endosperm large and horny; cotyledon small and leafy. Powdered Nux Vomica exhibits fragments of the endosperm, the cell-walls of which are very thick but not lignified, also slender rod-like fragments of the hairs and their thickened, pitted, lignified basal portions. No odor; taste extremely bitter. Yields not less than 1.25 per cent. of strychnine when tested by the following process." *Br.*

The seeds are destitute of odor, but have an acrid, very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. For a method of distinguishing powdered nux vomica from powdered ignatia and other powders, see *Proc. A. Ph. A.,* 1897, 503.

Herder has proposed a detection of the alkaloids in nux vomica by various microchemical means and shows how they may be localized in the seeds and growing plants. (*A. Pharm.,* 1906, p. 129.) Tunmann (*A. Pharm.,* 1910, 644) has studied the distribution of the alkaloids in the germinating seeds of *Strychnos Nux vomica,* and concludes that the embryo of the seed contained only brucine and that strychnine, which was contained in the endosperm only in the cell plasma of the cell content, appears to act as a protection for the growing plant. Grutterink has also published an illustrated article on the microchemical examination of the several alkaloids of nux vomica. (*Zeit. An. Chem.,* li, p. 187.) Rusby has reported the shipment of nux vomica which consisted of small inferior seeds which had been rolled in some mixture of clay. (*Proc. A. Ph. A.,* 1908, lvi, p. 794.) Powdered nux vomica has been adulterated with ground olive stones and the raspings of vegetable ivory. (See *Rep. d. Pharm.,* 1909, p. 241; *Ann. d. chim. Analyt.,* 1909, p. 261.)

The chemists Pelletier and Caventou discovered in nux vomica two alkaline principles, *strychnine* and *brucine,* united with a peculiar acid which they named *igasuric.* Its other constituents are a yellow coloring matter, a fixed oil, gum, starch, a small quantity of wax, and several earthy phosphates. Charles Bullock, in preparing the alcoholic extract of nux vomica with a moderate continuous heat, so as to dry it sufficiently to be pulverized, separated from 150 pounds of the seeds 5 pints of a liquid oil. This oil has a saponification number of 124, and an iodine number of 64 to 67. The unsaponifiable portion of the oil was identified as a mixture of phytosterin. (*A. Pharm.,* 1912, p. 398.) F. Meyer (*In. Dis.,* St. Petersburg, 1875) investigated the fatty oil from nux vomica, and found it to consist of the glycerides of capric, caprylic, caproic, butyric, and palmitic acids. (*A. J. P.,* 1874, 405.) Shenstone (*J. Chem. S.,* xxxix, 453) has shown that the *igasurine* of Desnoix is a mixture of strychnine and brucine. A glucoside, *loganin,* has also been found in the nux vomica seeds, but it exists more largely in the surrounding pulp. Dunstan and Short, its discoverers (*P. J.* 1883, xiv, 1025), gave to it the formula $C_{25}H_{34}O_{14}$. Boorsma stated that he had discovered a new alkaloid in the leaves of *S. Nux vomica* (*Bull. de l'Inst. Bot. de Buitenzorg*) and he named it *strychnicine;* it is only slightly poisonous. (See also *P. J.,* 1902, 65.)

Hugo H. Schafer (*J. A. P. A.,* 1914, p. 1077) announces a new alkaloid in nux vomica which he has named *struxine.* This alkaloid is stated to have the chemical formula $C_{21}H_{30}O_4N_2$. It is present only in the drug coming from Cochin China, and was found in an amount of 0.1 per cent.

Igasurine was said to be found in the mother waters from which strychnine and brucine have been precipitated by lime. Jörgensen believed that it was identical with brucine (see *A. J. P.,* June, 1872, p. 257), and W. A. Shenstone confirmed this view. (*A. J. P.,* Dec., 1881.)

Loganin is present in the pulp to the amount of 4 or 5 per cent., and is contained in small quantity also in the seeds. It was obtained by exhausting the pulp with a mixture of chloroform and alcohol (100 : 25). The exhaustion was effected in an apparatus for hot repercolation. The percolate, on cooling, deposited crystals, which when recrystallized a number of times from alcohol, and finally from absolute alcohol, were obtained pure. Loganin is easily soluble in water and alcohol, less soluble in ether, chloroform, and benzene. Its aqueous solution is not precipitated by any of the alkaloidal reagents. Its most characteristic reaction is found in its behavior with concentrated sulphuric acid. A very small quantity of loganin, when gently warmed with a few drops of concentrated sulphuric acid, yields a fine red color, which, on standing, develops into a deep purple. By boiling with dilute sulphuric acid, loganin is resolved into glucose (reducing Fehling's solution) and a body for which the name *loganetin* is proposed. This substance, like loganin, gives the characteristic reaction with sulphuric acid, but the purple color does not develop so rapidly. Loganetin is soluble in water and alcohol, less soluble in ether, carbon disulphide and chloroform. (*P. J.*, 1884, p. 1025.)

Strychnine ($C_{21}H_{22}O_2N_2$) was discovered by Pelletier and Caventou in 1818, in both the nux vomica and the bean of St. Ignatius, and received its name from the generic title of the plants (*Strychnos*) to which these two products belong. According to these chemists, it exists much more abundantly in the bean of St. Ignatius than in the nux vomica, the former yielding 1.2 per cent., the latter only 0.4 per cent., of strychnine, but Dragendorff obtained from nux vomica from 1.9 to 2.1 per cent. of mixed alkaloids, about half of which was strychnine. (*Jahresbericht*, 1874, 103.) For valuable practical information about the yield of the alkaloids, extracts, etc., by E. L. Patch, see *Proc. A. Ph. A.*, 1891, 91; also *P. J.*, 1889, 341; *Proc. Michigan Pharm. Assoc.*, 1889; *Proc. Ohio Pharm. Assoc.*, 1889; *P. J.*, 1890, 493.

Other species of *Strychnos* contain the poisonous alkaloids, and may some time become a commercial source of them. *Bidara laut* of the Indian bazaars, believed to be obtained from *S. ligustrina*, has been analyzed by Russow, who found the wood to contain 2.26 per cent. and the bark 7.38 per cent. of brucine without strychnine. Henry G. Greenish found in the wood and bark respectively of *S. colubrina* 0.96 per cent. and 5.54 per cent. of mixed alkaloids; the same analyst obtained from false Angustura bark (*S. Nux vomica*), young bark 3.10 per cent., old bark 1.68. (*P. J.*, 3d ser., ix, 1014.) According to Bernelot-Moens, the dry seeds of the *S. tieute* contain 1.469 per cent. of strychnine, with a trace of brucine. (*A. J. P.*, 1866, p. 506.) From the seeds of *Strychnos Rheedii*, W. R. Dunstan obtained a yield of 0.06 per cent. of brucine and no strychnine. (*Imp. Inst. Rep.*, 1901–1902.) The Congo poison known as *Cupua Apus*, according to Vinci (*A. I. P. T.*, xx), is produced from the *Strychnos kipapa*. The bark of the root contains 6 per cent. of strychnine and the wood 0.1 per cent.

Brucine ($C_{23}H_{26}O_4N_2$) was discovered by Pelletier and Caventou, first in the bark called *false Angustura*, in combination with gallic acid, and subsequently, associated with strychnine in the form of igasurates, in the nux vomica and the bean of St. Ignatius. It is crystallizable from alcohol, the crystals then containing $4H_2O$. It is without odor, but of a permanent, harsh, very bitter taste; is soluble in 850 parts of cold and in 500 of boiling water; very soluble in alcohol, whether hot or cold; it dissolves in 4 parts of chloroform, 440 parts of ether, 60 parts of benzene, and 120 parts of petroleum benzin. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. The hydrated crystals melt at 115° C. (239° F.), and sublime at 204° C. (399.2° F.), while the anhydrous base melts at 178° C. (352.4° F.), changing color, and depositing carbon. (*P. J.*, 1868, 375.) It forms crystallizable salts with acids. Concentrated nitric acid produces with brucine or its salts an intense crimson color, which changes to yellow by heat, and upon the addition of stannous chloride becomes violet. A test for brucine, given by Stanislas Cotton, consists in adding to a warm solution of brucine (from 40° to 50° C. (104°–122° F.)) in nitric acid, a concentrated solution of sodium thiosulphate. The mixture first becomes violet, and then passes to green when the alkaline salt is in excess. (*J. P. C.*, Juillet, 1869, 18.) These effects serve to distinguish brucine from strychnine, and, if produced with the latter alkaloid, evince the presence of the former. According to Larocque and Thibierge, auric chloride produces, with solutions of the salts of brucine, precipitates at first milky, then coffee-colored, and finally chocolate-brown. (*Journ. de Chim. Méd.*, Oct., 1842.) Chlorine water produces with solution of brucine a rose color, due to the formation of *dichlor-brucine*. This is a reddish-brown, hygroscopic powder. (*A. Pharm.*, 1886, 934.) A *dinitro-brucine*, $C_{23}H_{24}(NO_2)_2N_2O_4$, has also been obtained by the action of nitrogen trioxide upon the brucine in alcoholic solution. Brucine appears to bear a definite relation to strychnine in chemical constitution, being a *dimethoxy-strychnine*. According to the analyses of Shenstone and Dragendorff, the bark of the nux vomica contains brucine, with a trace of strychnine, while in the leaves Hooper found only brucine. (*P. J.*, 1890, xxi.)

Brucine may be procured from false Angustura bark, in a manner essentially the same as that in which strychnine is procured from nux vomica, with this difference, that the alcoholic extract obtained from the precipitate produced by lime or magnesia should be treated with oxalic acid, and subsequently with a mix-

ture of rectified alcohol and ether, which takes up the coloring matter, leaving brucine oxalate. This is decomposed by magnesia, and the brucine is separated by alcohol, which by spontaneous evaporation yields it in the state of crystals. Prescott (*Organic Analysis,* 1887, p. 458) gives two methods for the separation of strychnine from brucine; first, by the use of alcohol of 0.97 sp. gr., which easily dissolves brucine, but has very slight solvent power upon strychnine; second, by Dunstan and Short's method with potassium ferrocyanide. This method has been reported upon by Holst and Beckurts (*Ph. Centralh.,* N. F., 1887, p. 119), who find that if the hydrochloric acid solution containing mixed alkaloids is not too dilute, on the addition of potassium ferrocyanide the whole of the strychnine will be precipitated as ferrocyanide, while the brucine salt will remain in solution.

The separation of brucine from strychnine is most conveniently effected by exposing the mixed alkaloids to the action of diluted nitric acid, which destroys brucine very rapidly while having no appreciable action on strychnine; this method is used in the former official assay process.

Igasuric acid has been regarded as erroneously named, and investigators have stated that it was malic acid and tannic acid, while G. Sander (*A. Pharm.,* 1897, 133) believes that the acid found in nux vomica, heretofore known as igasuric acid, is *caffeo-tannic acid.*

The official process for determining the amount of alkaloids present in nux vomica is as follows:

Assay.—"Introduce 15 Gm. of Nux Vomica, in No. 40 powder, into a 250 mil flask and add 150 mils of a mixture of chloroform, 1 volume, and ether, 2 volumes. Stopper the flask, shake it well and allow it to stand ten minutes, then add 10 mils of ammonia water, and, after shaking the flask vigorously every ten minutes during two hours, allow it to stand ten hours. Now add 25 mils of distilled water, again shake the flask well, and, when the drug has settled, decant 100 mils of the solution, representing 10 Gm. of Nux Vomica, and proceed as directed under *Belladonnæ Radix,* page 222, beginning with the word 'filter,' line 12 of the Assay. For the titration, dissolve the alkaloids from the residue with 10 mils of tenth-normal sulphuric acid V.S. instead of 5 mils. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 36.4 milligrammes of the total alkaloids of Nux Vomica." *U. S.*

"Shake 7.5 grammes of Nux Vomica in No. 60 powder frequently during half an hour with a mixture of 25 millilitres of *chloroform,* 50 millilitres of *ether,* and 5 millilitres of *solution of ammonia.* Transfer 50 millilitres of the clear ethereal liquid to a separator, and extract the alkaloids by shaking with three successive portions, each of 10 millilitres, of *N/1 solution of sulphuric acid,* transferring the acid solutions to a second separator. Make the acid solutions alkaline with *solution of ammonia,* and again extract the alkaloids by shaking successively with 10, 5, and 5 millilitres of *chloroform,* drawing off the chloroformic solutions into a small flask. Recover the chloroform by distillation, dissolve the residue in a mixture of 5 millilitres of *diluted sulphuric acid* and 10 millilitres of water, heat the solution to 50° C. (122° F.), add 3 millilitres of a mixture of equal volumes of *nitric acid* and *water,* and set aside for ten minutes. Transfer the solution to a separator, rinsing the flask with a little *water,* make alkaline with *solution of sodium hydroxide,* and extract the alkaloid by shaking successively with 10, 5, and 5 millilitres of *chloroform.* Wash the mixed chloroformic solutions in a separator with 5 millilitres of *water,* transfer to a tared dish and allow the chloroform to evaporate, adding towards the end 5 millilitres of *alcohol* (90 per cent.). Evaporate to dryness, dry the residue at 100° C. (212° F.), and weigh. This weight, multiplied by 20, is the weight of strychnine in 100 grammes of the powdered Nux Vomica. Powdered Nux Vomica, when used for official purposes other than the production of standardised preparations, must be adjusted, if necessary, by the addition of powdered Milk Sugar to contain in 100 grammes 1.25 grammes of strychnine when tested by the foregoing process. *Limit of error* 0.05 gramme in excess or defect." *Br.*

As a test for nux vomica, Vielgruth proposes to treat a few grains of the suspected powder with proof spirit, evaporate the tincture to dryness at a heat not exceeding 35.5° C. (96° F.), then add a drop or two of diluted sulphuric acid, and again raise to the heat mentioned. If nux vomica be present, a beautiful carmine-red color will be produced, which will disappear in ten or fifteen minutes after cooling, and reappear, but less brightly, on the reapplication of the heat. Schweissinger recommended the direct determination of the alkaloids in nux vomica by titration with hydrochloric acid as the best way of ascertaining the strength of pharmaceutical preparations. (*A. Pharm.,* 1885, 579.) Keller's method of estimating the alkaloids in nux vomica (see *Proc. A. Ph. A.,* 1895, 1024) is commended by Sander. (*A. Pharm.,* 1897, 133; see also *A. J. P.,* 1896, 189.) A new method of assay for nux vomica and its preparations has been proposed by M. Azadain (*P. J.,* xciii, 371) which involves the precipitation of the alkaloids by silico-tungstic acid.

Uses.—The medicinal and toxic properties of nux vomica are those of its alkaloid. (See *Strychnina.*) The belief held by some physicians that it acts more favorably as a bitter upon the stomach has only this much of justification—namely, that it is more slowly absorbed, and therefore acts locally somewhat more persistently.

BRUCINE.—On account of the difficulty of separating strychnine from brucine, it has been found by physiologists difficult to determine the exact action upon the human organism of the pure alkaloid. It was formerly taught that

brucine closely resembled strychnine in its physiological action, except that it was less poisonous and that it was depressant to the peripheral sensory nerves. Dickson and Harvey (*P. J.*, 1908, lxxxi, p. 367), however, experimenting with a chemically pure brucine, reach the conclusion that its dominant action is a paralysis of the peripheral motor nerves, and that the convulsive action which is the characteristic effect of strychnine is almost entirely absent in the case of brucine. According to the observation of Mays, brucine is an active paralyzant to the sensory nerves and a 5 or 10 per cent. solution applied to the mouth causes local anesthesia. He has used it for the relief of *pruritus*. Burnett also asserts that a 5 per cent. solution is a valuable local anodyne in inflammations of the external ear.

Dose, of nux vomica, one to four grains (0.065–0.26 Gm.).

OLEA.

OILS

(ō'lę-a)

These are liquid or solid substances, unctuous to the touch and characterized by inflammability. They are divided into two classes, the *fixed* and the *volatile,* because distinguished, as their names imply, most readily by their different behavior on the application of heat.

OLEA FIXA. *Fixed Oils.*

Fats, Fatty Oils; Huiles Graisses, Huiles fixés, *Fr.;* Fette, Fette Oele, *G.;* Olios, *It.;* Aceites, *Sp.*

These are sometimes termed *fatty oils,* because they constitute in part the vegetable and animal fats. The distinction between liquid and solid fats is for the most part a physical one only, as they contain the same chemical compounds, although in relatively different proportions. The fatty oils, though existing in greater or less proportion in various parts of plants, are furnished for use exclusively by the fruit, and, as a rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press by exposing them to a moderate heat, so as to render the oil more liquid and thus enable it to flow out more readily. Another mode of extracting certain oils is by means of liquids having the power of dissolving them, and this method is now largely used in practice, carbon disulphide, carbon tetrachloride, and petroleum benzin being used. For the details of the process, see *A. J. P.,* Nov., 1868, 549. Fixed oils may be clarified and decolorized by subsidence, filtration through animal charcoal, clays or earths, or porous solids, precipitation with tannin, lead acetate, plaster of Paris, albumin, gelatin, or other agents; cellulose and asbestos filters are often used, and on the large scale, for separating mechanical impurities, centrifugal machines like those employed for milk. Some oils are given a preliminary treatment with sulphuric acid which is later removed by treatment with alkali. Fixed oils containing stearin or palmitin are likely to deposit these fats in cold weather, leaving the olein in a liquid condition. The olein may be separated by filtration in the cold.

Hydrogenated Fats and Oils.—A class of solid fats has appeared upon the market which are produced by a process known as hydrogenation, which is carried out in practice by bringing liquid fats into intimate contact with metallic catalyzers (finely divided nickel is usually employed), at elevated temperatures (160°–200° C. or 320°–392° F.). Under these conditions the unsaturated members of the fatty acid series which are usually liquid and are represented by oleic acid, become converted into the solid members of the series, which are saturated as stearic acid. The best known commercial product made in this way is the proprietary fat known as *Crisco,* largely used for culinary purposes.

Classification.

The following scheme of classification of the fixed oils, both liquid and solid (Allen, *Com. Org. Anal.,* 3d ed., vol. ii, Part I, pp. 88–102), gives a general view of their essential characters, points of difference, etc.

I. Olive Oil Group. *Vegetable Non-drying Oils.*—The oils of this group solidify on treatment with nitrous acid or mercuric nitrate, but do not lose their power of producing a greasy stain on paper, however long they may be exposed to the air. Their density varies from 0.914 to about 0.920, and hence is less than that of Groups III, IV, and V. Their viscosity is notably greater than that of the drying oils.

This group includes almond oil (from *Amygdalus communis*), peach oil (from kernels of *Prunus Persica*), apricot oil (from kernels of *Prunus armeniaca*), oil of ben (from *Moringa oleifera*), earth nut oil (from *Arachis hypogæa*), and olive oil (from *Olea europæa*).

II. Rape Oil Group.—The oils of this group are all derived from seeds of the family *Cruciferæ.* They are non-drying but less distinctly so than the oils of Group I. They show higher saponification values, higher iodine absorption and less solid elaidins than Group I.

This group includes Colza oil and rape seed oil (from *Brassica campestris, B. napus* and other species); oil of black mustard (from seeds of *Brassica nigra*); oil of white mustard (from seeds of *Sinapis alba*).

III. Cotton Seed Oil Group.—The oils of this group occupy a position intermediate between the vegetable non-drying and the true drying oils (Groups I and IV). In density they somewhat exceed the oils of Group I, but are lighter than those of Groups IV and V. They form more or less elaidin on treatment with nitrous acid or mercuric nitrate, but do not become wholly solidified. On the other hand, they undergo more or less drying on exposure to the air, but not so markedly as the oils of Group IV.

This group includes beech nut oil (from *Fagus sylvatica*), cotton seed oil (from *Gossypium* species), hazel nut oil (from *Corylus avellana*, see *Proc. A. Ph. A.*, 1893), sesame or teel oil (from *Sesamum orientale*), and sunflower oil (from *Helianthus annuus; H. perennis*), camelina oil (from *Myagrum sativum*), cress seed oil (from *Lepidium sativum*), and maize oil (*Corn Oil*).

IV. Linseed Oil Group. *Vegetable Drying Oils.*—These oils are not solidified by treatment with nitrous acid or mercuric nitrate, but become gradually converted into solid masses or varnishes, by exposure to the air. In density the oils of this group vary from about 0.923 to 0.937, and hence are distinctly heavier than the non-drying oils and than most of the oils of Group III. On the other hand, they are lighter than the oils of Group V. The fluidity of the drying oils is also much higher than that of the non-drying oils.

This group includes niger seed oil (from *Guizotia oleifera*), hemp seed oil (from *Cannabis sativa*), linseed oil (from *Linum usitatissimum; L. perenne*), poppy seed oil (from *Papaver somniferum*), Scotch fir seed oil (from *Pinus sylvestris*), tobacco seed oil (from *Nicotiana Tabacum*), walnut oil (from *Juglans regia*), weld seed oil (from *Reseda Luteola*), and soya bean oil (from *Soja hispidus*).

V. Castor Oil Group.—The oils of this group are distinguished from those of Groups I, II, III, and IV, by their very high density and viscosity. They are also remarkable for their ready solubility in alcohol, and their marked purgative properties. In their drying characters and behavior with the elaidin test they resemble the oils of the cotton seed oil group. Both castor and croton oil are miscible in all proportions with glacial acetic acid.

This group includes castor oil (from *Ricinus communis*), croton oil (from *Croton Tiglium*), Japanese or Chinese wood oil (from seeds of *Aleurites cordata* or *Elæococca vernicia*), boiled linseed oil, blown oils (made by oxidation of rape seed, cotton seed, linseed, lard, and other oils).

VI. Palm Oil Group. *Solid Vegetable Fats.*—This group includes solid fats not containing notable quantities of glycerides of lower fatty acids. The densities for the melted fats at 98° and 99° C. (208.4°–210.2° F.) are compared with the density of water at 15.5° C. (60° F.) taken as 1.000, and vary from 0.920 to 0.995.

This group includes palm oil (from fruit of *Elæis guineensis*), cacao butter (from nuts of *Theobroma Cacao*), nutmeg butter (from nuts of *Myristica fragrans*), and shea butter (from seeds of *Bassia Parkii*).

VII. Cocoanut Oil Group. *Solid Vegetable Fats.*—This group includes solid fats containing notable quantities of glycerides of lower fatty acids—that is, of acids distilling with more or less facility in a current of steam at 100° C. (212° F.). The group includes cocoanut oil (from the nuts of *Cocos nucifera*), palm oil (from the kernels of the nuts from *Elæis guineensis*), laurel oil (from fruit of *Laurus nobilis*), Japan wax (berries of *Rhus succedanea*), myrtle wax (berries of *Myrica cerifera*). For a description with constants of some of the rarer fixed oils belonging to the vegetable group, see papers by J. A. Wijs, *Ph. Ztg.*, 1903, 563; by Pancoast and Graham, *A. J. P.*, 1904, 70; and by Lewkowitsch, *P. J.*, 1904, 492.

VIII. Lard Oil Group. *Animal Oleins.*—This group includes those oils fluid at ordinary temperatures which are obtained from terrestrial animals. They resemble the whale or fish oils in their reaction with chlorine, but are not turned red or brown by boiling with caustic soda. On exposure to air and on treatment with nitrous acid or mercuric nitrate, they behave like the non-drying vegetable oils (Group I). This group includes bone oil, lard oil, tallow oil, and neat's-foot oil. For a paper by P. L. Simmonds on various animal oils, see *Bull. Pharm.*, 1893, 297, 344.

IX. Tallow Oil Group. *Solid Animal Fats.*—This group comprises oils that are solid or semisolid at ordinary temperatures. Their melting points vary somewhat, and are capable of permanent alteration. The group includes bone fat, butter fat, hog's lard, horse fat, beef tallow and mutton tallow.

X. Whale Oil Group. *Marine Animal Oils.*—This group comprises the various fluid oils obtained from fish and cetaceous mammals. They are distinguished as a class by their offensive fishy odor, by the brown color they assume when subjected to the action of chlorine, and by the reddish color which is produced on boiling them with a solution of caustic alkali. With sulphuric acid they give colorations varying from light red to purple or brown. The fish oils do not dry on exposure to air, and mostly yield but little elaidin on treatment with nitrous acid. The term "*train oil*" includes whale, seal, shark, cod, and all similar oils. Cod oil (from *Gadus morrhua* and allied species), cod liver oil (from the same), menhaden oil (from *Alosa menhaden*), porpoise oil (from *Delphinus phocæna* and allied species), seal oil (from *Phoca* of various species), shark oil (from *Squalus maximus* and allied species), and whale oil (from *Balaena mistecetus* and allied species) are all members of this group.

XI. Sperm Oil Group. *Liquid Waxes.*—The members of this group differ from all the fatty

oils of previous classes in not being glycerides, consisting essentially of esters of monatomic alcohols of the ethylic series, in which respect they resemble the true waxes, but are fluid at ordinary temperatures. They are less dense than glycerides, they do not dry or thicken notably on exposure to air, but they yield solid elaidins on treatment with nitrous acid. The group includes sperm oil (from cranial cavities of *Physeter macrocephalus*), doegling or bottle-nose oil, and dolphin oil.

XII. Spermaceti Group. *Waxes Proper.*—Spermaceti and the various waxes differ from the true fixed oils and fats in not forming glycerin when saponified, yielding instead certain of the higher monatomic alcohols, the identity of which varies with the nature of the wax. These alcohols are insoluble in water, and dissolve to but a limited extent in alcohol, but they are soluble in ether, chloroform, carbon disulphide, benzene, and petroleum benzin, and are apt to be mistaken for added paraffin wax when the substance is saponified and the soap extracted with a solvent.

This group includes beeswax (from honeycomb of various species of bees), Carnauba or Brazil wax (from the leaf-coverings of *Copernicus cerifera*), Chinese wax or Pela wax (produced by a species of *Coccus* which punctures the branches of certain trees), myrtle wax (from berries of *Myrica cerifera*), Ocuba wax (from *Myrica Ocuba*), palm wax (from bark of *Ceroxylon andicola*, of the Cordilleras), and spermaceti (deposit from the oil found in the cranial cavities of the sperm whale, *Physeter macrocephalus*). Wool fat, which consists largely of *cholesterol* (an alcohol), belongs to this group.

When oils are decomposed by heat they emit vapors of *acrolein allyl aldehyde*, CH_2CHCHO, a highly volatile liquid resulting from the decomposition of glycerin, upon which the fumes of oils mainly depend for their irritating effects on the eyes and nostrils. Exposed to a red heat, in closed vessels, they yield, among other products of the destructive distillation, a large quantity of combustible and illuminating gases, among which ethylene and acetylene are readily recognized. Heated in the open air, they take fire, burning with a bright flame, and producing water and carbon dioxide. When kept in air-tight vessels, they remain unchanged for a great length of time, but exposed to the atmosphere they attract oxygen and undergo change.

Effervescent Oils.—K. Dieterich recommends oils and fats which have been supersaturated with carbon dioxide and introduced by him under the name of "effervescent oils." (See *Proc. A. Ph. A.*, 1900, 494.) Under the influence of carbon dioxide, compounds which are easily split with the fatty acids are produced, which, particularly in the case of cod liver oil, permit the more complete absorption of the oil than is the case with oil not treated with carbon dioxide. The latter, moreover, acts as a preservative of the oils and renders them more palatable, destroying the unpleasant taste of cod liver oil, and to a certain extent also that of added medicaments, very materially. The absorbability of carbon dioxide is, however, not the same in all oils. Cod liver oil is capable of absorbing the largest quantity, castor oil the smallest, while olive oil stands intermediate. (*Ph. Centralh.*, 1901, 485.)

Some fixed oils, in drying, lose their unctuous character, and are converted into a transparent, yellowish, flexible solid. These are called *drying oils.* Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste and an unpleasant odor. This change is owing to the development or liberation of free fatty acids, from which the oil may be freed by boiling it for a short time with magnesium hydroxide and water.

Cloes has made investigations in relation to the influence of light in promoting oxidation, and obtained some curious results. The general influence of light is very great, as oils undergo comparatively little change in the dark for a long time; though in relation to some of them the change is at length as great as under the light. Thus, while the oil of poppies had in 30 days increased about 5 per cent. in weight under white light, and had gained only a 5000th in the dark, yet at the end of 150 days the weight in the former condition was rather lessened than augmented, and in the latter, or in the dark, had increased 6.4 per cent. The effect of the different colored rays is also very different. The change is at first most rapid under the white light, less so under the blue, and much less under the red, yellow, and green, being least of all with the green; but with the advance of time the blue overtakes and even passes the white and at the end of three or four months all are about equal in effect. Heat also accelerates the concretion of the oils, by favoring their oxidation; and the same effect is produced by introducing into the unchanged oil a little which has already been altered by exposure to the air. The oxidation of an oil may be very greatly hastened in this way without the aid of heat.

The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they are enabled to dissolve sulphur and phosphorus. The stronger acids decompose them, giving rise, among other products, to oleic, palmitic, and stearic acids. Boiled with diluted nitric acid, some of them give rise to malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They are sa-

ponified by various alkalies. The compounds which these acids form with potassium and sodium hydroxide are the common detergent soaps, although strictly speaking, a soap is the combination of a fatty acid with any metal or base. (See *Sapo* and *Emplastrum Plumbi.*) By the addition of one part of potassium or sodium carbonate, 160 parts of oil may be brought with distilled water into the form of an emulsion. The potassium and sodium soaps and the alkaline sulphides have a similar effect, but not the bicarbonates. The fixed oils also serve as good vehicles for various metallic bases and subsalts, which form soaps to a certain extent soluble in the oil, and thus become less irritant to the tissues. Oils thus impregnated may, like the pure oils, be brought to the state of emulsion with water, for convenient administration, by the addition of a small proportion of potassium carbonate. The fixed oils dissolve many of the alkaloids, the volatile oils, resin, and other proximate principles of plants. The alkaloids are more readily dissolved in them by being first combined with oleic acid, the oleates being more soluble than the alkaloids themselves. According to Buignet, they are, with very few exceptions, indifferent to polarized light; of all those used in medicine, the only exceptions are the liver oils of the ray and dog fish, which have a very feeble lævorotatory power, and castor oil, which is decidedly dextrogyrate.

It is very likely that, with the exception of castor oil, whose rotatory power is due to the asymmetric carbon atom of the ricinoleic acid, the rotatory power is not due to the glycerides themselves but to small proportions of optically active substances such as cholesterol. (Lewkowitsch, *Chem. Analysis of Oils Fats and Waxes,* p. 121.)

The fixed oils, whether animal or vegetable, in their natural state consist in most cases of at least two or three distinct constituents, one liquid at ordinary temperatures, and the other two solid or semisolid. The liquid is a distinct proximate principle, called *olein;* the more solid principles consist of *stearin* and *palmitin,* the former being found most largely in animal and the latter in vegetable oils or fats, and the two in most cases existing together in the same oil. The substance formerly known as *Margarin* is now generally recognized to be a mixture of palmatin and stearin. As the most frequent of these proximate constituents of the fixed oils, and existing in many different oleaginous substances, olein, palmitin, and stearin merit a special notice. Preliminarily to their individual consideration, it will be proper to refer to their nature and composition generally.

These three substances, *olein, palmitin,* and *stearin,* together with *butyrin, caprin,* and other minor fat principles, are *glycerides;* that is, esters or salts of the triatomic alcohol glycerol, $C_3H_5(OH)_3$, and of the several fatty acids, oleic, palmitic, stearic, etc., all of which are monobasic acids. The three mentioned glycerides have the following composition:

$$\text{Olein (triolein)},\ C_3H_5\begin{cases}OC_{18}H_{33}O\\OC_{18}H_{33}O\\OC_{18}H_{33}O\end{cases}$$

$$\text{Palmitin (tripalmitin)},\ C_3H_5\begin{cases}OC_{16}H_{31}O\\OC_{16}H_{31}O\\OC_{16}H_{31}O\end{cases}$$

$$\text{Stearin (tristearin)},\ C_3H_5\begin{cases}OC_{18}H_{35}O\\OC_{18}H_{35}O\\OC_{18}H_{35}O\end{cases}$$

There are also mixed glycerides exemplified by the following formula:

$$\text{(oleopalmitostearin)}\quad C_3H_5\begin{cases}OC_{18}H_{33}O\\OC_{16}H_{31}O\\OC_{18}H_{35}O\end{cases}$$

When these substances, or oils composed principally of them, are treated with alkali with the aid of heat, decomposition takes place, which may be illustrated as follows:

$$C_3H_5\begin{cases}OC_{18}H_{33}O\\OC_{18}H_{33}O\\OC_{18}H_{33}O\end{cases}+3NaOH=$$

$$C_3H_5\begin{cases}OH\\OH\\OH\end{cases}+3Na.OC_{18}H_{33}O$$

that is, olein is decomposed by sodium hydroxide into *glyceryl hydroxide,* or *glycerin,* and *sodium oleate,* or a sodium soap.

The waxes differ from the fats proper in being esters of the higher monatomic alcohols like *cetyl alcohol,* $C_{16}C_{33}.OH$, and *myricyl alcohol,* $C_{30}H_{61}.OH$, instead of being glycerides. The fatty acids present are partly palmitic and stearic, but more largely still higher ones, like *cerotic acid,* $C_{27}H_{54}O_2$.

Other fatty acids represented in fixed oils are: butyric acid, $C_4H_8O_2$; valeric acid, $C_5H_{10}O_2$; caproic acid, $C_6H_{12}O_2$; caprylic acid, $C_8H_{16}O_2$; capric acid, $C_{10}H_{20}O_2$; lauric acid, $C_{12}H_{24}O_2$; myristic acid, $C_{14}H_{28}O_2$; arachidic acid, $C_{20}H_{40}O_2$; erucic acid, $C_{22}H_{42}O_2$; hypogæic acid, $C_{18}H_{30}O_2$. The first few members of the above list are known as the volatile fatty acids, which serve as the basis for the determination of what is known as the Reichert-Meissl number.

Olein. Elain. Liquid Principle of Oils.—It is extremely difficult to obtain olein pure. Being in most oils associated with the solids stearin and palmitin, it must be separated by pressure and other mechanical means, which separation is not always perfectly effected. As ordinarily procured, therefore, olein contains more or less

of palmitin or stearin, or both. In this somewhat impure state it is obtained either by the agency of alcohol or by expression. When one of the oils, olive oil, for example, is dissolved in boiling alcohol, the solution, on cooling, deposits the concrete principles, still retaining the olein, which it yields upon evaporation. The other method consists in compressing one of the solid fats, or one of the liquid oils rendered concrete by cold, between folds of bibulous paper, which absorb the olein, and give it up afterwards by compression under water. Olein is a liquid of oily consistence, congealing at –6° C. (21.2° F.), colorless when pure, with little odor and a sweetish taste, insoluble in water, soluble in boiling alcohol and ether. Its formula, as already stated, is $C_3H_5(OC_{18}H_{33}O)_3$, being an oleate of the triad radical *glyceryl*, C_3H_5. By reaction with nitric acid, or, more exactly stated, under the influence of nitrous acid fumes, olein is converted into a deep yellow, butyraceous mass. If this be treated with hot alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains, called *elaidin*. This is white, crystalline, fusible at 34° C. (93.2° F.), insoluble in water, readily soluble in ether, and appears to be isomeric with olein. It is resolved by saponification with the alkalies into *elaidic acid* and glycerin.

Palmitin.—Palmitic acid occurs in the more liquid fats, such as palm oil and cocoa-nut oil, as well as in butter and human fat, as glyceride, while in spermaceti and some forms of wax it is combined with monatomic alcohol radicals. Palmitin is the *palmitic acid glyceride*, or *glyceryl tripalmitate*. It is best obtained from palm oil.

Stearin.—This exists abundantly in tallow and other animal fats. It may be obtained by treating the concrete matter of lard, free from olein, by cold ether so long as anything is dissolved. The palmitin is thus taken up, and stearin remains. A better method is to dissolve suet in heated oil of turpentine, allow the solution to cool, submit the solid matter to expression in unsized paper, repeat the treatment several times, and finally dissolve in hot ether, which deposits the stearin on cooling. This is concrete, white, opaque in mass, but of a pearly appearance as crystallized from ether, pulverizable, fusible at 66.5° C. (151.7° F.), soluble in boiling alcohol and ether, but nearly insoluble in those liquids cold, and quite insoluble in water. It consists of glyceryl and stearic acid in combination as a glyceride, $C_3H_5(OC_{18}H_{35}O)_3$, and has been formed synthetically by heating a mixture of these two materials to 280° to 300° C. (536°–572° F.).

Commercially the fixed oils are frequently sold under the names *summer pressed* and *winter pressed*. These were once really seasonal designations, as an oil pressed during the warmer months would contain more dissolved stearin and would consequently congeal or cause a deposit when chilled, while an oil pressed during cold weather would remain transparent at low temperatures, and thus *winter pressed* oils were safer for lubricating purposes and commanded a higher price. Artificial refrigeration now makes it possible to make either grade of oil at any season of the year, although the former seasonal names are still used.

The fixed oils are liable to certain spontaneous changes, which have been investigated by Pelouze and Boudet. It appears from their researches that the oils are accompanied, in the seeds which contain them, with principles which act as a ferment and cause the oils to resolve themselves spontaneously into the several fatty acids which they afford on saponification, and into glycerin. This change takes place in the seeds as soon as the cells containing the oils are broken, so as to permit the contact of the fermenting principle existing in the grain. The decomposition of fats by the action of enzymes has been made a working method capable of technical application, by Connstein, Hoyer and Wartenburg. The enzyme contained in the castor oil bean has been found best adapted for this. An emulsion of fats, water, 10 per cent. of ground castor oil beans and a small amount of free acid are used, when the decomposition proceeds rapidly. As rancidity in fats renders them altogether useless in pharmacy, and as it is not always readily discoverable by the senses in its earlier stages, it becomes desirable to possess a test by which it may be detected. Such a test is to be found, according to Thos. B. Groves, in potassium iodide, which is rapidly decomposed by the new principles developed, and the orange-brown discoloration produced by the liberation of the iodine indicates the existence of rancidity, and the degree of that discoloration, approximately, the extent of the change. The alteration of color is said by Groves to be plainly perceptible when only one-twentieth of rancid fat is present. The presence of water in a fatty oil favors the production of rancidity.

It is also extremely important to be able to protect fats against this change. The complete exclusion of air, light, and moisture—and, when in relation to air this may not be entirely practicable, the destruction by heat of the ferment-germs contained in the air, by which the decomposition is often originated—will go far to effect this object; but it would often be very inconvenient, if not impossible, to carry these measures into complete effect, and hence the discovery of substances which may have the effect of retarding, if not wholly preventing, these fermenting processes, whether by the destruction of the ferment-germs or otherwise, is extremely desirable; this preservative effect has been known and practically used many years, and since the principle upon which they are supposed to act has been discovered the number has been extended. Thus, benzoin rubbed up with fats is well known to preserve them long against rancidity, and *benzoinated lard*, made by extracting ten per cent. of benzoin with melted lard, is one of the official

preparations, and the buds of the poplar (*Populus nigra*) are perhaps still more effectual, as, according to Deschamps, lard impregnated with their virtues will keep good indefinitely. In the French Codex the poplar buds are employed in the *Pommade de Bourgeon de Peuplier,* in which 8 parts of the dried buds are used to 40 parts of the ointment, consisting of lard impregnated with the virtues of several narcotic substances, the fresh narcotic plants being boiled with lard until all their water is evaporated, and the buds afterwards digested in the strained liquid for twenty-four hours. Groves made experiments with many volatile oils and other analogous substances to test their preservative power. (See *A. J. P.,* 1865, 54, 61.) Hirzel says that animal fats may be kept in a good condition for a year by the following plan. Mix 14 pounds of the recently melted fat with 5 drachms of common salt and 15 grains of alum, in fine powder, heat till a scum is formed on the surface, separate the scum, and, when the clear liquid has cooled, wash it many times with water with malaxation, so as to remove all the salt, then evaporate the water at a heat insufficient to injure the fat. (*A. J. P.,* 1868, 334.)

The adulteration of the fixed oils may be effected in several ways—by admixture with the fatty oil of substances distinctly foreign to the fats, and by adding a cheaper or inferior oil to one of greater value. In the former case we may have the addition of paraffin wax, ceresine, mineral oils, neutral tar oils, resin oils, resin, and waxes. Of these, the first three are entirely unsaponifiable, resin oils contain but small quantities of saponifiable substances, waxes are partly saponifiable, and resin almost completely saponifiable. The determination of unsaponifiable matter is therefore of great importance. The common method for this is to saponify the suspected sample with alcoholic potassium hydroxide and then to shake out the unsaponifiable matter with ether or petroleum ether. From this solution, on evaporation, will be obtained the mineral, resin, or tar oils that may have been present. For these there are appropriate tests elsewhere noted. In case a cheaper oil or fat has been added for the purpose of adulterating a more valuable one, we must be guided by the determination of certain constants, such as those mentioned below by Cowley, or by the indication of certain qualitative color tests. The constants referred to are much more to be depended upon in such a case.

R. C. Cowley (*P. J.,* 1897, 331) regards the following as the most important determinations in examining fats and fixed oils. 1. Specific gravity. 2. Melting and solidifying points. 3. Melting and solidifying points of fatty acids. 4. Behavior with solvents. 5. The Hehner value. 6. The Reichert-Meissl value. 7. The saponification value. 8. The iodine value. To these have been added during recent years: 9. The refractive index. 10. The acetyl number. 11. The temperature rise with sulphuric acid (Maumené number).

It is sometimes desirable to deprive the fixed oils of color. The following process for this purpose is recommended by Brunner. The oil is first brought to the state of emulsion by strongly agitating it with water rendered mucilaginous by gum or starch; the emulsion is treated for each part of oil with two parts of wood charcoal, previously well heated and coarsely powdered, the finer particles being sifted out; the pasty mass is then completely dried at a heat not exceeding 100° C. (212° F.), and exhausted by cold ether in a percolator; finally, the ethereal solution, having been allowed to stand, in order that any charcoal present in it may subside, is submitted to distillation, so as to separate the ether, and the oil remains colorless in the retort. (*J. P. C.,* Sept., 1858.) Berlandt recommends the following method: Shake strongly for some minutes 900 parts of the fixed oil with 120 parts of water holding in solution 3 parts of potassium permanganate, allow the mixture to stand for some hours in a warm place, and then filter. The oil becomes colorless. (*J. P. C.,* Oct., 1867.)

The modern method of decolorizing vegetable oils is to filter them through kaolin or Fuller's earth. Preliminary treatment with acids and alkalies is sometimes advisable.

OLEA VOLATILIA. [*Olea Destillata.*]

Volatile Oils.

Olea Ætherea, Ætherolea; Ethereal Oils, Essential Oils, Distilled Oils; Huiles Volatiles, Huiles Essentielles, Huiles Distillées, Essences, *Fr.;* Flüchtige Oele, Aetherische Oele, *G.;* Essenze, *It.;* Esencias, *Sp.*

These are sometimes called *distilled oils,* from the mode in which they are usually procured; sometimes *essential oils,* from the circumstance that they possess, in a concentrated state, the organoleptic properties of taste and odor of the plants from which they are derived. The word *essence* is used in some countries to designate the volatile oils themselves, but in America this word has unfortunately been largely applied to the alcoholic solutions of the volatile oils, usually called the *spirits,* and the word *soluble essence* has been used to describe hydroalcoholic solutions of volatile oils which possess the property of mixing clear with water.

The term *Ætherolea* is used in some countries to distinguish the volatile oils in general from those which are produced by destructive distillation, like oil of amber, oil of cade, oil of tar, etc., which are given the collective name *pyrolea* (pyroligneous oils).

They exist in all odoriferous vegetable tissues, sometimes pervading the plant, sometimes confined to a single part; in some instances contained in distinct cells, and partially retained after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as formed. Occasionally two or more are found in different parts of the same plant. Thus, the orange tree produces one oil in its leaves, another in its flowers, and a third in the rind of

its fruit. In a few instances, when existing in distinct cells, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally procured by steam distillation. (See page 738.) Some volatile oils, as those of bitter almond and mustard, are formed in the presence of moisture out of substances of a different nature pre-existing in the plant, and may be subsequently distilled.

The volatile oils are usually colorless when freshly distilled, or at most yellowish, but some are brown, red, green, or blue. There is reason, however, to believe that in all instances the color depends on foreign matter dissolved in the oils. Septimus Piesse succeeded, by the fractional distillation of certain volatile oils, in separating a blue liquid, which, by repeated rectification, he has obtained quite pure. In this state it has the sp. gr. 0.910, and a fixed boiling point of 302.3° C. (576° F.), and yields a dense blue vapor having peculiar optical properties. He named this principle *azulene,* and believed that upon it depends the blueness of volatile oils wherever existing. The yellowness of the oils he ascribed to the resin resulting from their oxidation, the green and brown colors to a mixture of azulene and resin in various proportions. The formula of azulene he gave as $C_{15}H_{26}O$. (*Chem. News,* Nov. 21, 1863, p. 245.) Gladstone named this blue coloring constituent *cærulein,* and stated that it contains nitrogen and is colored green by acids and alkalies. The volatile oils differ from the fixed oils in not yielding glycerol when treated with alkalies.

The volatile oils have a strong odor, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and, when they are diluted, is often gratefully aromatic. The greater number are lighter than water, though some are heavier; their sp. gr. varies from 0.847 to 1.17. They vaporize at ordinary temperatures, diffusing their peculiar odor, and are completely volatilized by heat. When distilled alone, they nearly always undergo partial decomposition. Heated in the open air, they take fire and burn with a bright flame attended with much smoke. Almost all of them are optically active, and advantage may sometimes be taken of this property to detect adulterations of one of these oils with another. The refractive index is another physical constant that is being studied in connection with volatile oils, but the accumulation of data is not yet sufficiently large to give the factor much value as yet. Exposed at ordinary temperatures, some of them absorb oxygen, assume a deeper color, become thicker and less odorous, and are ultimately converted into resin. This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation.

The volatile oils are sometimes hydrocarbons, although with these are frequently associated alcohol- or ketone-like bodies called *camphors,* and products of oxidation known under the general name of resins, and undoubtedly formed from the hydrocarbons. Phenols, aldehydes, esters, ethers, and sulphides are also represented. The hydrocarbons are generally known as *terpenes,* from oil of turpentine, which is taken as a type. *Olea ætherea sine terpeno* is the name proposed by Schweissinger for concentrated volatile oils made so by the removal of the non-fragrant hydrocarbon, and representing from two to thirty volumes of the ordinary essential oils. Thus, one volume of the concentrated oil represents two volumes of the oils of anise, cassia, fennel, gingergrass, mentha crispa, mentha piperita, cloves, sassafras, and star anise; two and one-half volumes of the oils of bergamot, caraway, and lavender; four volumes of cumin and rosemary; five volumes of thyme; six volumes of coriander; eight volumes of calamus; ten volumes of absinthe; twenty volumes of juniper; thirty volumes of angelica, lemon and orange. It is asserted that these concentrated oils are more permanent, more soluble in alcohol and in water, have a finer odor, and are of constant composition, thus enabling the specific gravity and boiling point to be used as tests of purity. They should be kept in the dark. (*Ph. Centralh.,* 1888, No. 25.) Under the name of "*terpeneless volatile oils,*" similar products can now be found in the market; they are undoubtedly superior to the ordinary volatile oils both in odor and strength.

Wallach, to whom much of our knowledge on volatile oils is due, divides the hydrocarbons into classes, as follows:

1.—*True terpenes,* of the formula $C_{10}H_{16}$, of which there are two main groups: (*a*) the *terpane* group, uniting with two molecules of haloid acid or four atoms of bromine; this group includes limonene, dipentene, sylvestrene, terpinolene, terpinene, thujene, and phellandrene, and its members boil between 175° and 185° C. (347° and 365° F.); (*b*) the *camphane* group, uniting with one molecule of haloid acid or two atoms of bromine; this group includes pinene, bornylene, camphene, and fenchene, and its members boil between 151° and 161° C. (303.8° and 321.8° F.).

2.—*Hemiterpenes,* of the formula C_5H_8, such as isoprene.

3.—*Polyterpenes,* such as cedrene, cubebene, etc., of the formula $C_{15}H_{24}$ (sesquiterpenes); colophene, of the formula $C_{20}H_{32}$; and caoutchouc, of the formula $(C_{10}H_{16})_x$.

Hydrocarbons other than those of the terpene class or derivable from them, occur very sparingly in the natural oils. Thus there is of the paraffin series of saturated hydrocarbons, *heptane,* C_7H_{16}, occurring in the oil from the *Pinus sabiniana,* or California *digger pine,* and solid hydrocarbons of the same series in oil of rose, and probably in oils of wintergreen and sweet birch. Of the benzene series there is a single representative in *cymene,* $C_{10}H_{14}$, found in the oils of the *Thymus* and *Monarda* species.

In addition to these naturally occurring hydrocarbons, there is a class of artificially pre-

pared hydrocarbons known as *hydroterpenes*, such as dihydrodipentene from dipentene, menthene and carvomenthene from menthol and carvone.

The terpenes in general are practically insoluble in water, but soluble in alcohol, ether, chloroform, benzene, petroleum benzin, and the fixed and volatile oils.

Many of the essential oils, however, owe their essential character and their value to other constituents than hydrocarbons. We shall briefly notice the most important of these, either describing them or referring to other places in the text where they are already described, and shall then give a classification of the commonly known essential oils based upon the character of the most important compounds present in them.

I. Alcohols.

Geraniol, Linalool, Citronellol, Terpineol, Menthol, Borneol, Nerol, Sabinol, Santalol.

II. Aldehydes.

Citral, Citronellal, Salicyl Aldehyde, Cumic Aldehyde, Benzaldehyde, Cinnamic Aldehyde, Anisic Aldehyde, Piperonal, Santalal.

III. Ketones.

Methyl-amyl-ketone, Ionone, Methyl-nonyl-ketone, Methyl-heptenone, Carvone, Pulegone, Menthone, Camphor, Fenchone, Thujone, Irone.

IV. Esters.

Methyl Salicylate, Methyl Anthranilate, Benzyl Acetate, Linalyl Acetate, Geranyl Acetate, Bornyl Acetate, Menthyl Acetate, Bornyl Valerate, Geranyl Tiglate.

V. Phenols and Phenol Ethers.

Chavicol, Methyl-chavicol, Anethol, Thymol, Carvacrol, Eugenol, Methyl-eugenol, Iso-eugenol, Chavibetol, Safrol, Iso-safrol, Thymohydroquinone dimethyl ether, Asarol, Apiol, Diosphenol.

VI. Neutral Bodies, Oxides, etc.

Cineol (*Eucalyptol*).

VII. Sulphides and Sulphur Compounds.

Diallyl Disulphide, Allyl Isothiocyanate, Dimethyl Sulphide, Butyl Isothiocyanate, Vinyl Sulphide, Acrinyl Isothiocyanate, Phenyl Ethyl Isothiocyanate.

The classification of the volatile oils in any rational and practical manner is a difficult task.

Any system that is devised is either exceedingly complex and cumbersome or, if conciseness is attempted, there are too many inconsistencies and discrepancies. For instance, one of the favored methods of classification is to divide them into four groups, *i.e.*, the terpenes, oxygenated oils, nitrogenated oils, and sulphurated oils. If this be critically studied it is seen that oil of lemon, which is usually given as a typical example of the terpene class, owes its real identity and value to citral, an aldehyde present in only a very small proportion (less than 5 per cent.), and that oil of bitter almond, which is given as the example of the nitrogenated class, owes its classification in this respect only to the incidental presence of hydrocyanic acid, which is frequently removed from the oil, especially when it is used for flavoring purposes. This leaves the sulphurated class, which contains only one important member and the oxygenated class, which is the repository of over 90 per cent. of oils of diversified character.

It is therefore more suitable to follow the foregoing outline adding such explanatory matter and examples as will serve to make it intelligible and valuable for either study or reference purposes.

NOTE.—Although the alcohols only were mentioned in the first group given above it will be found convenient to refer to the more important esters of these alcohols as they are taken up for discussion.

I. Alcohols and Their Esters.—This is an interesting group of open chain, unsaturated alcohols, which, with their esters and aldehydes, play a very important part in the composition of many essential oils. It is the geraniol, linalool and citronellol group.

1.—*Geraniol*, $C_{10}H_{17}OH$, or $\begin{matrix}CH_3\\CH_3\end{matrix}\!>\!C=CH.CH_2.CH_2.C\!<\!\begin{matrix}CH_3\\CH.CH_2OH\end{matrix}$, is a colorless liquid of a pleasant rose geranium odor, boiling at 229° to 230° C. (444.2°–446° F.), under ordinary pressure, and at 129° C. (264.2° F.) under a pressure of 16 mm. Its specific gravity is about 0.881 and its refractive index 1.478. It is optically inactive. By careful oxidation with chromic trioxide it yields its aldehyde, citral, and by heating it in an autoclave with water to 200° C. (392° F.), it is partly converted into its isomer, linalool. It is a monatomic, primary, open chain alcohol, and is the principal constituent of true geranium (pelargonium) oil, as well as of the so-called "*Turkish geranium oil*," or *oil of palmarosa*. It is a constituent of rose oil, of citronella oil and in very small proportions of a number of other oils. Of the esters of geraniol the most important is the *geranyl acetate*. This is a fragrant oil of specific gravity 0.917, boiling at from 128° to 129° C. (262.4°–264.2° F.), under a pressure of 16 mm. It occurs naturally in several essential oils, and can be made artificially by the action of acetic anhydride upon geraniol. Commercial geraniol is also known as *rhodinol*.

2.—*Linalool*, $C_{10}H_{17}OH$, or $\begin{matrix}CH_3\\CH_3\end{matrix}\!>\!C=CH.CH_2.CH_2.C\!<\!\begin{matrix}CH_3\\OH\end{matrix}\!-\!CH=CH_2$, is known in both of the optically active forms as well as

in the inactive. It is a liquid having a pleasant odor, and boils under normal pressure at about 198° C. (388.4° F.), and at from 86° to 87° C. (186.8°–188.6° F.) at 14 mm. pressure. Its specific gravity ranges from 0.868 to 0.877, and its refractive index is 1.463. It is a monatomic, tertiary, open chain alcohol, and is an essential constituent of oil of linaloe, and is found in the free state or as an acetic ester in oils of bergamot, coriander, lavender, neroli, etc. The most important of its esters is *linalyl acetate,* which occurs in many essential oils, as in oil of bergamot. It is an odoriferous liquid of the specific gravity 0.912, and boiling at from 105° to 108° C. (221°–226.4° F.) at 11 mm. pressure. It is so prepared artificially, and the artificial ester is an important commercial article.

3.—*Citronellol,* $C_{10}H_{19}OH$, or $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!C\!-\!CH_2.CH_2.CH_2.CH\!<\!\begin{matrix}CH_3\\CH_2.CH_2OH\end{matrix}$, is found in oil of rose and in Spanish geranium oil. It is an odoriferous oil, boiling at from 117° to 118° C. (242.6°–244.4° F.), under a pressure of 17 mm.; specific gravity, 0.8565 at 17.5° C. (63.5° F.); refractive index, 1.457. It is an open chain alcohol closely related to geraniol and is found in oil of rose, oil of geranium, etc. When obtained from oil of rose it is lævogyrate, while when obtained by reducing the aldehyde it is dextrogyrate; in most geranium oils both varieties exist.

A second group comprises the mono-cyclic alcohols, terpineol, which is unsaturated, and menthol, a saturated compound.

4.—*Terpineol,* $C_{10}H_{17}OH$, $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!CH\!-\!COH.CH_2.CH_2.CH_2.CH.C\!-\!CH_3$, occurs in liquid and solid modifications, inactive, as well as in the two optically active, varieties. Besides occurring naturally it is made artificially by the dehydration of terpin hydrate, and is largely used in the perfume industry because of its lilac odor. It has a sp. gr. of 0.940 at 15° C. (59.2° F.). Its most important ester is the acetate, which occurs in cajuput and cardamom oils.

5.—*Menthol, menthyl alcohol,* $C_{10}H_{19}OH$, $\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!CH\!-\!CH.CH_2.CHOH.CH_2.CH_2CH\!-\!CH_3$, is now official, and will be found described on page 695. Two of its esters are recognized as occurring with it in peppermint oil, menthyl acetate and menthyl iso-valerate. Of these the former is the more important. It is an oil having a penetrating odor, boiling at 224° C. (435.2° F.).

To a third group of compounds known as dicyclic, belongs:

6.—*Borneol,* $C_{10}H_{17}OH$, or $CH.CH_2.CH_2.CH_2.CH_3.C.CH_3.CH_2.CHOH.C\!-\!CH_3$.—This compound occurs naturally in both optically active modifications. It also occurs optically inactive. It forms crystalline masses, which, when quite pure, melt at 203° C. (397.4° F.). Borneol can be prepared artificially by reducing its ketone (camphor) with metallic sodium. In this case, however, there results a mixture of borneol and iso-borneol. Borneol forms a number of esters, of which *bornyl acetate* is the most important. This compound melts at 29° C. (84.2° F.), and has a specific gravity of 0.991 at 15° C. (59° F.). It is the characteristic constituent of the pine needle oils.

Nerol is an alcohol discovered in oil of neroli. It is a stereo-isomer of geraniol. Santalol, so called, is found as an alcoholic constituent of oil of sandalwood. It has been given the formula $C_{15}H_{25}OH$, but is probably a mixture of several isomeric or closely related alcohols. Sabinol, $C_{10}H_{15}OH$, is a constituent of oil of savin.

Fenchyl alcohol, thujyl alcohol, and pulegol, all having the same empiric formula as geraniol, $C_{10}H_{17}OH$, do not occur naturally, but are produced from the respective ketones.

II. Aldehydes.—Of the alcohols just enumerated, only the first group are primary alcohols, and will yield aldehydes. Thus, from geraniol, there is obtained by oxidation, citral, the corresponding aldehyde, and from its isomer, linalool, the same.

1.—*Citral,* $C_9H_{15}COH$, or $(CH_3)_2C.CH.CH_2.CH_2.C(CH_3)CH.COH$.—Although at one time called *geranial,* this compound is now universally known as citral, which indicates its importance in the oils of the *citrus* family. It is obtained most abundantly from lemon grass oil by the aid of the bisulphite process. It is an oily liquid, boiling at from 228° to 230° C. (442.4°–446° F.), under ordinary pressure, and at 110° C. (230° F.), under 12 mm. Its specific gravity is about 0.89 and its refractive index 1.49. It is optically inactive. Under the influence of alkalies, citral condenses with acetone with the elimination of water to form pseudo-ionone, $C_{13}H_{20}O$, which is converted into its isomer ionone by means of acids. Reduction with sodium produces the alcohol geraniol.

2.—*Citronellal,* $C_9H_{17}OH$, or $C(CH_3)_2CH.CH_2CH_2CH(CH_3)CH_2COH$, the aldehyde of citronellol, occurs in several essential oils, as in citronella oil. It is an oily liquid of characteristic odor; specific gravity 0.8768, refractive index 1.4481. It is dextrogyrate.

Of the class of aromatic aldehydes, there are found in essential oils, salicyl aldehyde, cumic aldehyde, benzaldehyde, and cinnamic aldehyde.

3.—*Salicyl Aldehyde,* $C_6H_4(OH)COH$.—This body is an oily liquid of aromatic odor, boiling at 196° C. (384.8° F.), and having a specific gravity of 1.172. It occurs in the oils of the several varieties of *Spiræa.* It can also be formed by the oxidation of its alcohol saligenin, or by the action of chloroform and potassium hydroxide on phenol.

4.—*Cumic Aldehyde,* $C_6H_4(C_3H_7)COH$.—This is p-isopropyl-benzaldehyde, and is found in several essential oils, as in cumin oil. It is an aromatic oil, having a specific gravity of 0.973, and boiling at 235° C. (455° F.).

5.—*Benzaldehyde,* $C_6H_5.COH$.—This is now official. (See page 223.)

6.—*Cinnamic Aldehyde,* $C_6H_5.CH:CH.COH$. —This was official in the U. S. P. VIII.

Anisic Aldehyde, $C_6H_4(OCH_3)COH$ (oxymethyl-benzaldehyde), is a synthetic product used in artificial hawthorn perfume.

Piperonal or *Heliotropin,* $C_6H_3O_2CH_2COH$, is a synthetic product used in heliotrope perfume.

Santalal, $C_{14}H_{23}COH$, is found in sandalwood oil.

III. Ketones.—This class of chemical compounds is largely represented in essential oils. Of aliphatic saturated ketones there is only one fairly important representative.

1.—*Methyl-nonyl-ketone,* $CH_3.CO.C_9H_{19}$, which is found in oil of rue, is a liquid of strong odor, boiling at 225° C. (437° F.), and specific gravity 0.8295 at 17° C. (62.6° F.). It solidifies when cooled, and melts at 13° C. (55.4° F.).

Of aliphatic unsaturated ketones there is also one occurring naturally.

2.—*Methyl-heptenone,* $CH_3.CO.C_6H_{11}$, is found in lemon grass oil and other oils, and results from the oxidation of citral or the distillation of cineolic anhydride. It has a specific gravity of 0.853 at 20° C. (68° F.) and boils at 174° C. (345.2° F.).

A *methyl-amyl-ketone,* $C_5H_{11}COCH_3$, boiling at 151° C. (303.8° F.) and having a specific gravity of 0.837 at 50° C. (122° F.), is found as a minor constituent in oil of cloves.

The most commonly occurring ketones, however, belong to the cyclic compounds:

3.—*Carvone,* $C_{10}H_{14}O$, $CH_3C\begin{matrix}\diagup\!\!\diagup CH—CH_2\\ CO—CH_2\end{matrix}\rangle CH—C\begin{matrix}\diagup CH_3\\ \diagdown CH_2\end{matrix}$. —This compound, found in oils of caraway fennel and dill, is a colorless oil boiling at 225° C. (437° F.) and having a sp. gr. of 0.960 at 18° C. (64.4° F.). It is optically active, occurring in both forms. Its most interesting addition compound is that with hydrogen sulphide; this is obtained in crystals, decomposing with alcoholic potassium hydroxide and liberating pure carvone. When heated with glacial phosphoric acid, it is changed into the isomeric carvacrol, a phenol compound.

4.—*Pulegone,* $C_{10}H_{16}O$, $CH_3CH\begin{matrix}\diagup CH_2—CO\\ \diagdown CH_2—CH_2\end{matrix}\rangle C{=}C\begin{matrix}\diagup CH_3\\ \diagdown CH_3\end{matrix}$.—This characteristic ketone of pennyroyal oil is a liquid boiling at 221° C. (429.8° F.), and having a specific gravity of 0.9323 at 20° C. (68° F.). An isomeric body, iso-pulegone, has been obtained artificially.

5.—*Menthone,* $C_{10}H_{18}O$, $CHCH\begin{matrix}\diagup CH_2—CH_2\\ \diagdown CH_2—CO\end{matrix}\rangle CHCH(CH_3)_2$.—This occurs along with the corresponding secondary alcohol menthol, in oil of peppermint. It is an oily liquid boiling at 206° C. (402.8° F.), with a specific gravity of 0.897 at 15° C. (59° F.). By the action of oxidizing agents it can be converted into thymol, $C_{10}H_{14}O$.

To the class of dicyclic ketones belong the following isomeric bodies:

6.—*Camphor,* $C_{10}H_{16}O$, $C_8H_{14}\begin{matrix}\diagup CH_2\\ \diagdown CO\end{matrix}$.—This most important compound of the ketone class is official, and is described on page 270.

7.—*Fenchone,* $C_{10}H_{16}O$, $\begin{matrix}CH_2—CH_2—\!\!-CCH_3\\ \quad\quad\quad\quad\quad\quad\diagup\\ \quad\quad\quad C(CH_3)_2\\ \quad\quad\quad\quad\quad\quad|\\ CH_2—CH—\!\!-CO\end{matrix}$.— This ketone occurs as dextro-fenchone in oil of fennel, and as lævo-fenchone in oil of thuja. When purified, it forms an oil of camphoraceous odor, boiling at 193° C. (379.4° F.), and having a specific gravity of 0.9465 at 19° C. (66.2° F.).

8.—*Thujone,* $C_{10}H_{16}O$, $CH_3—CH\begin{matrix}\diagup CO—CH_2\rangle\\ \diagdown CH—CH_2\end{matrix}C—CH\begin{matrix}\diagup CH_3\\ \diagdown CH_3\end{matrix}$.—This ketone is found in oils of thuja, tansy, wormwood and sage, and is identical with the bodies formerly known as *tanacetone* and *salvone.* It is an optically active liquid, boiling at from 200° to 203° C. (392°–397.4° F.) and having a specific gravity of 0.9126 at 20° C. (68° F.).

A more complex ketone yet to be noted is:

9.—*Irone,* $C_{13}H_{20}O$, $(CH_3)_2C\begin{matrix}\diagup CH(CH:CH.\\ \diagdown CH:CH—\end{matrix}CO.CH_3)CH.CH_3\rangle CH_2$.—The characteristic constituent of orris oil, to which also the violet odor is due, is irone. It is an oil almost insoluble in water, but readily soluble in alcohol, boiling at 144° C. (291.2° F.) at 16 mm., and having a specific gravity of 0.939 at 20° C. (68° F.). In the attempt to effect the synthesis of irone, Tiemann and Krüger obtained an isomeric body, *ionone,* from citral, which is now used as the artificial violet odor.

IV. Acids and Their Esters.—While esters of several of the fatty acids, both saturated and unsaturated, are found in the essential oils, the compounds are not so distinctive or characteristic, that they require mention here. Some of the esters have been already described under the appropriate alcohols, see geraniol, linalool, etc. Of esters of aromatic acids there are several of importance, however, comprising the most valuable constituents of the oil in which they occur.

1.—*Methyl Salicylate* is the chief constituent of the oils of wintergreen and sweet birch. As it is now official as a pure compound, it is described on page 696.

2.—*Methyl Anthranilate* (*o-amidobenzoate*), $C_6H_4(NH_2)COOCH_3$.—This is the odoriferous constituent of neroli oil. It is an oil solidifying at low temperatures in crystals melting at 24.5° C. (76.1° F.), and boiling at 127° C. (260.6° F.) at 11 mm. Its specific gravity is 1.163 at 26° C. (78.8° F.). It is strongly fluorescent and has a powerful neroli odor.

V. Phenols and Phenol Ethers.—This is an important class, largely represented in the volatile oils. Of monatomic phenols there are:

1.—*Chavicol* (para allyl-phenol), $C_6H_4(OH)C_3H_5$.—This occurs in the *oil of Chavica Betle*, and is a colorless liquid having a strong odor and a specific gravity of 1.035 at 20° C. (68° F.), boiling at 237° C. (458.6° F.). Still more abundantly formed in nature is its methyl ether, which is:

2.—*Methyl-chavicol*, $C_6H_4(OCH_3)C_3H_5$.—This occurs in the oils of anise, star anise, sweet-basil, bay, etc. It is a colorless liquid of an anise-like odor, boiling at from 215° to 216° C. (419°–420.8° F.), and having a specific gravity of 0.979 at 12° C. (53.6° F.).

3.—*Anethol*, $C_6H_4(OCH_3)C_3H_5$, is the methyl ether of p-propenyl-phenol, and is therefore isomeric with methyl-chavicol. It can be formed from the latter by heating it with alcoholic potassium hydroxide. It is the most abundant constituent of the oils of anise, star anise and fennel. It forms white scales having a specific gravity of 0.986 at 25° C. (77° F.), melting at 21° C. (69.8° F.), and boiling at 232° C. (449.6° F.).

4.—*Thymol* (methyl-propyl-phenol), $C_6H_3.CH_3(OH)C_3H_7$ 1 : 3 : 4.—This is one of the best known of the phenols occurring in volatile oils. As it is official its description will be found under *Thymol*.

5.—*Carvacrol* (methyl-propyl-phenol), $C_6H_3.CH_3(OH)C_3H_7$ 1 : 2 : 4.—This important phenol, occurring in oils of marjoram and savory, is isomeric with thymol. It is a thick oil, solidifying at 0° C. (32° F.) and boiling at 236° C. (456.8° F.). It can be prepared artificially by heating carvone, an isomeric ketone, with phosphoric acid or by heating camphor with iodine.

Of diatomic phenols and their ethers, there are the following:

6.—*Eugenol*, $C_6H_3.OH.OCH_3.C_3H_5$ 4 : 3 : 1, is the methyl ether of allyl-dioxybenzene. It occurs in the oils of cloves, allspice, bay, Ceylon cinnamon and cinnamon leaves. As it is now official, its description will be found on page 432.

7.—*Methyl-eugenol*, $C_6H_3.(OCH_3)_2.C_3H_5$, is found together with eugenol in oil of bay. It has a specific gravity of 1.041 at 11° C. (51.8° F.) and boils at 248° C. (478.4° F.).

8.—*Iso-eugenol* is the methyl ether of propenyl-dioxybenzene, and is produced from eugenol when the latter is heated with alcoholic potassium hydroxide. It is used in the manufacture of artificial vanillin.

9.—*Chavibetol*, $C_6H_3(OCH_3)OH$, is another isomer of eugenol, and occurs with chavicol in oil of betel leaves.

10.—*Safrol*, $C_6H_3\begin{matrix}O\\O\end{matrix}\!\!>CH_2.C_3H_5$, is the methylene ether of allyl-dioxybenzene. It is found quite largely in the oils of sassafras, camphor, etc. It was official in the U. S. P. VIII.

11.—*Iso-safrol* is the methylene ether of propenyl-dioxybenzene, and is produced from safrol by heating the latter with alcoholic potassium hydroxide. It is used in the manufacture of *piperonal* (artificial heliotropin).

12.—*Thymohydroquinone dimethyl-ether*, $C_6H_2.(OCH_3)_2.CH_3.C_3H_7$, constitutes the bulk of the oil of arnica root. It is a liquid distilling at from 248° to 250° C. (478.4°–482° F.).

Of triatomic phenols and their ethers, the representative is:

13.—*Asarol*, $C_6H_2(C_3H_5)(OCH_3)_3$.—This is the trimethyl ether of propenyl-trioxybenzene. It forms the solid constituent of the oil of *Asarum europæum*, and occurs in prisms melting at 61° C. (141.8° F.), and boiling at from 295° to 296° C. (563°–564.8° F.). It has also been made synthetically.

Of tetratomic phenols and their ethers, there is also a representative, as follows:

14.—*Apiol*, $C_{12}H_{14}O_4$, $C_6H_6(OCH_3)_2O_2.CH_2$, is the dimethyl-methylene ether of allyl-tetroxybenzene. It occurs in two isomers—the apiol from oil of parsley and dill apiol from some varieties of oil of dill. Of these, the former is a crystalline solid melting at 30° C. (86° F.) and boiling at 294° C. (561.2° F.) and the latter is an oily liquid boiling at 288° C. (550.4° F.).

VI. Neutral Bodies, Oxides, etc.—One important compound of frequent occurrence in volatile oils has not been classified under any of the preceding groups, for the reason that it is relatively inert in a chemical way and is considered as an oxide of neither distinct acid or basic character.

1.—*Cineol* (*Eucalyptol*), $C_{10}H_{18}O$.—This is found in nature in large amounts in eucalyptus oil (hence the name "eucalyptol" sometimes given to it), in cajuput oil (hence the name of "cajuputol"), in lavender, wormseed, and other oils. As it is now official under the name of *eucalyptol*, its description will be found on page 429.

VII. Sulphides and Sulphur Compounds.

1.—*Di-allyl-disulphide*, $C_6H_{10}S_2$, is a constituent of oil of garlic and occurs in many oils belonging to the *Cruciferæ*. It is a liquid of very unpleasant odor, boiling at 140° C. (284° F.)

2.—*Allyl-isothiocyanate*, $C_3H_5.NCS$, is the principal constituent of the volatile oil of mustard. It is, however, a decomposition product of the glucoside potassium myronate, which breaks up under the influence of the ferment myrosin. The allyl thiocyanate can also be obtained artificially by distilling allyl iodide or bromide with alcoholic potassium thiocyanate. This artificial product is largely sold in place of the natural oil. It is a liquid having a very unpleasant odor, boiling at 151° C. (303.8° F.), and having a specific gravity of 1.017 at 10° C. (50° F.).

Vinyl sulphide, $(C_2H_3)_2S$, is found in a variety of garlic.

Butyl isothiocyanate, $CH(CH_3)C_3H_5NCS$, is found in oil of horseradish, *acrynyl isothiocyanate*, C_7H_7ONCS, is found in white mustard

and *phenylethyl isothiocyanate,* $C_2H_4(C_6H_5)NCS$, is found in oil of mignonette.

CLASSIFICATION.

Classification of the more commonly occurring volatile oils.—In considering the question of classifying the volatile oils, two methods of arrangement naturally suggest themselves, viz.: a classification according to the botanical natural orders to which they belong, and a chemical classification based on the most important chemical constituents of the oils themselves. While the first of these is the more readily made, it suffers from the disadvantage of being cumbrous and less readily understood except by the botanist. On the other hand, the second plan shows at a glance the sources of the valuable odoriferous and medicinally and technically important constituents for which the volatile oils are largely used. That it has not been generally adopted is no doubt due to the fact that many of the oils contain several different constituents of value, and it is therefore difficult to make an assignment of some of them to individual chemical groups. Nevertheless, it is believed that the chemical classification adopted here will be found to have practical value for reference.

Group I.—*Oils containing mainly Terpenes and Sesquiterpenes.*

Oil of Cedarwood; cedrene and cedrol (an oxygenated constituent).
Copaiba Balsam; caryophyllene.
Cubeb; cadinene and cubeb camphor (an oxygenated constituent).
Dog Fennel; phellandrene.
Fleabane; d-limonene.
Galbanum; pinene and cadinene.
Ginger; sesquiterpene and phellandrene.
Hemp; cannibene and other terpenes.
Hops; humulene and tetrahydrocymene.
Myristica; terpenes and myristicol (an oxygenated constituent).
Orange; limonene with small amount of citral and citronellal (both oxygenated constituents).
Turpentine; pinene and sylvestrene.

Group II.—*Oils containing mainly Alcohols and their esters.*

a. Aliphatic saturated alcohols:
Oil of Heracleum; octyl alcohol and octyl ester.

b. Aliphatic unsaturated alcohols:
Oil of Bergamot; linalool and linalyl acetate.
Coriander; linalool and d-pinene.
Geranium; geraniol and geranyl esters.
Lavender; linalyl acetate and geraniol.

Group II.—(*Continued.*)

Lime; linalyl acetate and limonene.
Linaloes; linalool and geraniol.
Petit Grain; linalool and linalyl acetate.
Rose; geraniol and citronellol with esters.

c. Monocyclic and dicyclic alcohols.
Oil of Angostura; galipol, galipene, and cadinene.
Fir Cones; bornyl acetate and terpenes.
Golden Rod; borneol and bornyl esters.
Juniper Berries; juniper camphor and cadinene.
Ledum; ledum camphor.
Lovage; terpineol.
Mace; myristicol.
Patchouli; patchouli camphor and cadinene.
Peppermint; menthol and menthone.
Pine Needles; bornyl acetate and terpenes.
Rosemary; borneol and bornyl acetate.
Sandalwood; santalol and esters.
Savin; sabinol and sabinyl acetate.
Valerian; borneol and bornyl esters.

d. Aromatic Alcohols and Esters:
Oil of Jasmine; benzyl acetate and benzyl alcohol.

Group III.—*Oils containing Aldehydes as characteristic constituents.*

a. Aliphatic unsaturated aldehydes:
Oil of Citron peel; citral and limonene.
Citronella; citronellal and geraniol.
Lemon; Citral and citronellal (this oil might also properly be classed in Group I, as the terpenes constitute over 90 per cent. of the oils).
Lemon grass; citral, citronellal, and methyl-heptenone.
Verbena; citral.

b. Aromatic aldehydes:
Oil of Bitter Almond; benzaldehyde.
Cassia; cinnamic aldehyde.
Cinnamon; cinnamic aldehyde and eugenol.
Cumin; cumic aldehyde.
Meadow Sweet; salicyl aldehyde.

Group IV.—*Oils containing Ketones as characteristic constituents.*

a. Aliphatic saturated aldehydes:
Oil of Rue; methyl-nonyl-ketone.

b. Aliphatic unsaturated aldehydes:
Oil of Lemon grass; methyl-heptenone.

Group IV.—(*Continued.*)

c. Monocyclic and dicyclic ketones:

Oil of Artemisia; thujone.
Camphor; camphor.
Caraway; carvone and limonene.
Dill; carvone and limonene.
Orris; irone.
Pennyroyal; pulegone.
Peppermint; menthone and menthol.
Sage; thujone with borneol and cineol.
Spearmint; carvone.
Tansy; thujone with borneol.
Thuja; thujone and fenchone.
Wormwood; thujone and thujyl alcohol.

Group V.—*Oils containing Esters.*

a. Aliphatic Acids:

Oil of Angelica; methyl-ethyl-acetic esters.
Calamus; heptylic and palmitic acid and esters.
Cardamom; acetic esters and cineol.
German Chamomile; caproic acid esters.
Roman Chamomile; butyric, angelic and tiglic esters.

b. Aromatic acid esters:

Oil of Neroli; o-amido-benzoic-methyl ester.
Sweet Birch; methyl salicylate.
Gaultheria; methyl salicylate.

c. Undetermined acids:

Oil of Celery; sedanolide and lactone.
Elecampane; alantic acid and lactone.

Group VI.—*Oils containing Phenols and Phenol Ethers.*

a. Monatomic phenols and their ethers:

Oil of Ajowan; thymol and cymene.
Anise; anethol and methyl-chavicol.
Betel; chavicol and methoxy-chavicol.
Fennel; anethol and fenchone.
Marjoram; carvacrol and linalool.
Savory; carvacrol, pinene, and cymene.
Star Anise; anethol, methyl-chavicol and safrol.
Sweet Basil; Methyl-chavicol and d-linalool.

b. Diatomic phenols and their ethers:

Oil of Arnica Root; thymohydroquinone dimethyl-ether.
Bay; eugenol, methyl-eugenol and methyl-chavicol.
Camphor; safrol, eugenol and camphor.
Cascarilla Bark; eugenol and terpenes.

Group VI.—(*Continued.*)

Cinnamon Leaf; eugenol and cinnamic aldehyde.
Cloves; eugenol and sesquiterpene.
Pimenta; eugenol and sesquiterpene.
Sassafras; safrol and camphor.

c. Triatomic phenols and their ethers:

Oil of Asarum; asarol and methyl-eugenol.
Matico; asarol.

d. Tetratomic phenols and their ethers:

Oil of Parsley; apiol.

Group VII.—*Oils containing Neutral Bodies.*

Oil of Cajuput; cineol, terpineol and terpenyl acetate.
Eucalyptus; cineol, pinene, and aldehydes.
Laurel Leaves; cineol and pinene.
Myrtle; cineol, d-pinene and dipentene.
Wormseed; cineol and dipentene.

Group VIII.—*Oils containing Sulphur.*

Oil of Asafœtida; sulphides and pinene.
Garlic; diallyl-disulphide and allylpropyl sulphide.
Mustard; allyl-thiocyanate, allyl-cyanide and carbon disulphide.
Onion; allyl-propyl sulphide.

Properties.—Volatile oils are slightly soluble in water. Agitated with this fluid they render it milky, but the major portion separates upon standing, leaving the water impregnated with their odor and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing them. Trituration with insoluble powders, as tale, magnesium carbonate, kieselguhr, etc., renders them much more soluble, probably in consequence of their minute division. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. The hydrocarbon oils are scarcely soluble in diluted alcohol, and, according to De Saussure, the solubility of volatile oils generally in this liquid is proportionate to the oxygen which they contain. The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposit them on cooling. By long boiling with sulphur they form brown, unctuous, fetid substances, formerly called *balsams of sulphur.* They absorb chlorine, which converts them into resinous oxidation products and then combines with these. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with some organic acids. When treated with a caustic alkali, some of them are saponified or otherwise decomposed. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resinous oxidation products. The volatile oils dissolve many of the proximate

principles of plant and animal tissues, such as the fixed oils and fats, resins, camphor, and many of the alkaloids when in the free state. Exposed to air and light, many of them absorb oxygen and become what are termed ozonized oils which possess oxidizing properties.

Adulterations.—The volatile oils are often sophisticated. Among the greater adulterations are fixed oils, resinous substances, chloroform, hydrocarbon oils, and alcohol, but the most dangerous are those made by mixing the pure oil with the cheaper volatile oils and terpenes and fractions from other oils like limonene. The presence of the fixed oils may be known by the permanent greasy stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol be present, the oil will become milky when agitated with water in a graduated tube, and after the separation of the liquids the water will occupy more space and the oil less than before. The following method of detecting alcohol was proposed by Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remains for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than 4 per cent. If it disappears in five minutes, the oil contains more than 4 per cent. of alcohol; if in less than a minute, 25 per cent. or more. Borsarelli employs calcium chloride for the same purpose. This he introduces in small pieces, well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two-thirds filled with the oil to be examined, and heats the tube to 100° C. (212° F.), occasionally shaking it. If there is considerable proportion of alcohol, the chloride will be entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces will lose their form, and collect at the bottom in a white adhering mass; if none at all, they will remain unchanged. (*J. P. C.*, xxvi, 429.) J. J. Bernoulli proposes as a test dry potassium acetate, which remains unaffected in a pure oil, but will be dissolved if alcohol be present, and form a distinct liquid. (See *A. J. P.*, xxv, 82.) Distillation, catching the first portion, and testing for alcohol by the iodoform reaction, will detect very small additions of alcohol. The most dangerous adulterant of volatile oils is a liquid sold under some "fancy name," found in the markets of London and other large cities, and recommended for "reducing" essential oils; one specimen examined by John Barclay (*P. J.*, 1896, 463) had a delicate odor, and could be mixed with oils of lemon and bergamot without being detected by odor or taste. It was believed to be a *lævo-pinene*. There are good reasons for believing that similar liquids are used to an enormous extent.

Sometimes volatile oils of little value are mixed with the more costly. The taste and odor afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of purity. When two oils, of which one is lighter and the other heavier than water, are mixed, they may be separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities, but it sometimes happens that an unadulterated oil may thus be separated into two portions. The difference of apparent effect produced by iodine with the several oils has been proposed as a test, and bromine was employed for the same purpose by John M. Maisch, who used both these tests preferably in the state of ethereal solution, which, as it is liable to spontaneous change by keeping, should be prepared when wanted for use. According to Liebig, when iodine is made to act on a volatile oil, a portion of it combines with the hydrogen of the oil, forming hydriodic acid, while another portion takes the place of the lost hydrogen. Oil of turpentine may be detected by remaining in part undissolved when the suspected oil is treated with three or four times its volume of alcohol of the sp. gr. 0.84; or, according to Mero, by causing the suspected oil, when agitated with an equal measure of poppy oil, to remain transparent, instead of becoming milky, as it would do if pure. The latter test will not apply to the oil of rosemary. (*J. P. C.*, 3e sér., vii, 303.) G. S. Heppe suggests a very delicate test of oil of turpentine and most other non-oxygenated oils, when used to adulterate one of the oils containing oxygen. A piece of copper nitroprusside, of the size of a pin's head, is put into a little of the suspected oil in a test-tube, and heated until the liquid begins to boil. The boiling must be continued only a few seconds. If the oil be pure and oxygenated, the copper nitroprusside will become black, brown, or gray; if oil of turpentine or other non-oxygenated oil be present, the deposit will be green or bluish-green, and the supernatant liquid colorless or yellowish.

The different relations of the volatile oils to polarized light may, to a certain extent, be made available for the detection of adulterations, especially where the action of the adulterating oil is in an opposite direction to that of the oil adulterated. Thus, the oils of juniper, lavender, and rosemary, rotate the plane of polarization to the left, while American oil of turpentine rotates it to the right; and if this should be added to one of the other oils it might in some degree neutralize their action, and thus offer one means for its detection. Unfortunately, the French oil of turpentine, from the juice of the *Pinus maritima*, acts strongly in the opposite direction. But the very strength of its left-rotatory power might lead to its detection by the abnormal increase

of this power which it would impart to the oils in question. Synthetic or artificial volatile oils are now largely manufactured. They vary greatly at times in their resemblance to the natural products. They will be considered under their respective titles elsewhere, a number having received official recognition.

Volatile oils may be preserved without change in small, well-stoppered amber-colored bottles, entirely filled with the oil, and secluded from the light.

They may also be preserved by mixing with them about 5 per cent. of a bland fixed oil which will remain undissolved when the volatile oil is added to alcohol and for which allowance must be made, of course, in the volume of the oil used in formulas, etc. (LaWall, *Proc. A. Ph. A.*, 1910, 1121.)

Manufacture.—Most of the volatile oils may be prepared by the general formula of the U. S. P. 1870: "Put the substance from which the Oil is to be extracted into a retort or other vessel suited for distillation, and add enough water to cover it; then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."

A large proportion of the volatile oils of European commerce is produced in Grasse, a town of France, twenty-five miles west of Nice. For an elaborate article on this industry and methods of preparation, see *A. Pharm.*, xxii, 473, abstracted in the *P. J.*, vol. xv, 468. Schimmel & Co., Miltitz, Germany, are large producers of volatile oils.

Under the general observations on the *Aquæ*, or *Waters*, will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed in either the recent or the dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt or by means of glycerin, as they afford little or no oil after desiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh, although it is thought by some that when moderately dried they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water until they are thoroughly penetrated by this fluid, and to facilitate the action of the water it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising or other similar mechanical operation.

The water which is introduced into the still with the substance answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, although in most instances readily rising with the vapor of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 100° C. (212° F.), and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 110° C. (230° F.). Recourse may also be had to a bath of strong solution of calcium chloride, or to an oil bath. Other oils, again, may be volatilized with water at a temperature below the boiling point, and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a wire basket, or to place it upon a perforated shelf, in the upper part of the still, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil it *in vacuo*. Duncan stated that the most elegant volatile oils he had even seen were prepared in this manner by Barry, the inventor of the process. The employment of steam heat also prevents injury, and the best volatile oils are now prepared by manufacturers in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stop-cock, by which the pressure of the steam may be regulated and the water drawn off when necessary. In some instances it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almond. The same method is applicable to the preparation of distilled waters.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution when the mixed vapors are condensed, and if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled, and there will be danger of the substance in the still adhering to the sides of the vessel and thus become burnt. (See page 180.) Enough water should always be added to cover the solid material and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of material in the still should not exceed three-fourths of its capacity, as otherwise there would be danger of the liquid boiling over. The form of the still has an influence over the quantity of water distilled, which de-

pends more upon the extent of surface than upon the amount of liquid submitted to evaporation. By employing a high and rather narrow vessel one may obviate the disadvantage of an excessive quantity of water. Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the still is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, until the quantity of oil exceeds the solvent power of the water. This process is called *cohobation.*

The more volatile of the oils pass with facility along with the steam into the neck of the common still, but some which are less volatile are apt to condense in the head and thus return into the still. For the distillation of the latter, a copper still should be employed having a very low head. As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tubes should be straight, rather than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, are rendered solid by a comparatively slight reduction of temperature, and that in the distillation of these the water employed for refrigeration should not be below 5.5° C. (42° F.).

The mixed vapors are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it, the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the liquid coming over has a milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florentine receiver* may be used. For illustrations of this, and other forms of receivers, for collecting and separating immiscible liquids, see Remington's *Practice of Pharmacy,* 6th edition, p. 250. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downward. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and, rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates as long as the process continues, but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled; but, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separator* is usually employed for this purpose. It consists of a glass funnel, or a globular vessel, furnished with a stopper, and prolonged at the bottom into a very narrow tube. The lower opening being closed, the mixed liquids are introduced and allowed to stand until they separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened, so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separator; if lighter, it remains within. According to George Leuchs, all oils obtained by distillation with water, even when perfectly clear, contain some water.

The water saturated with oil should be preserved for use in future distillations, as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as acetic, butyric, or valerianic, and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (*J. Pr. Chem.,* lxiv, 499.) For an illustration of a cheap apparatus for distilling volatile oils by steam under slight pressure, see *Proc. A. Ph. A.,* 1894, 680.

According to Overbeck, all the volatile oils may be decolorized by distilling them from an equal weight of poppy seed oil and a saturated solution of common salt. (*A. Pharm.,* lxxxiv, 149.)

When first procured, some volatile oils have a disagreeable somewhat empyreumatic odor, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be filtered and introduced into small opaque bottles, which should be well stoppered so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality by agitation with a little recently heated animal charcoal, and the same method may be employed for freeing them from adhering water.

They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming *oleosaccharates,* which are then dissolved in water; or made into emulsions with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almond for example, and then to emulsionize the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic,

and 25 of syrup may be taken. The volatile oils are often kept dissolved in alcohol under the name of essences.

Enfleurage.—This term is applied by the French to the impregnation of fixed oils and fatty matters with the odors of certain sweet scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well be separated by distillation. The process consists in exposing the fatty matter, placed in layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odor to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. (*A. J. P.*, xxix, 551.) The French sometimes give to the spirituous solutions made by extracting the odors from fats and oils with alcohol the name of *Essences*.

The following suggestions on preparing emulsions of the volatile oils may be useful. Oil of turpentine and other volatile oils, to be emulsionized in quantity, are most successfully treated by rubbing them with one-half their weight of powdered gum arabic, and, when intimately mixed, adding at once, with rapid trituration, water in the proportion of one and a half times the weight of the gum used. Such an emulsion is more permanent when a little fixed oil is used.

Uses.—While substances differing so widely in their source and in their chemical composition must manifestly exercise dissimilar effects upon the body, but there are certain properties common to so many of the volatile oils that a word concerning the therapeutic effects of this group of principles may be in place. Practically all of the official volatile oils are more or less irritant; some of them only feebly so and some very actively so. By virtue of this action when taken into the intestinal tract they excite peristalsis and are therefore used for the expulsion of flatus in *colic* as well as to enhance the effect of cathartic drugs. It is probably also to this local irritant effect that their uses as expectorants, diaphoretics, and diuretics is to be attributed. A large number of them are powerful germicides and nearly all of them more or less antiseptic. The antibacterial property of the volatile oils has been investigated especially by Martindale (*Perfume and Essential Oil Record*, 1910, i, p. 266) by Gilmore (*P. J.*, 1910, p. 844) and by Peck (*J. A. M. A.*, 1899, xxxii, p. 6). According to Martindale the oil of origanum is twenty-five times as actively germicidal as phenol and the oil of cloves about 9 times; while Peck finds that the oil of cloves prevents the multiplication of bacteria when present in about 1 part to 1100. The following volatile oils are powerfully germicidal: origanum, thyme, cinnamon, cassia, cloves, bay, and sassafras. Of considerable disinfectant power but weaker than the preceding are: peppermint, eucalyptus, cajuput, bitter almond, sandal wood, spearmint and lavender. The following are feeble in their antibacterial properties: anise, bergamot, juniper, cade, and turpentine. Concerning most of the other oils figures are lacking. While the cost of the volatile oils precludes their use for many disinfectant purposes yet for others they are very valuable agents, especially are they employed for their antibacterial properties in the mouth and nose.

Some of the essential oils possess marked local anesthetic powers, among which may be mentioned especially cloves, peppermint, thyme, and cajuput. For this influence they are used in *toothache* and *pruritus*.

OLEATA.

OLEATES

(ō-lę-ā'tą)

Oléates, *Fr.*; Oleate, *G.*

The *oleates* are a class of preparations which were introduced to the medical profession by John Marshall, F.R.S., in 1872. They are usually solutions of certain bases in oleic acid, and are made by triturating the solid substance with the oleic acid until it is dissolved. Whenever it is possible, the application of heat should be avoided, and it has been observed that the freshly precipitated oxides of the metals dissolve more readily than those which are old. The title oleate is probably the best that could be devised, although it must be understood that, as found in the Pharmacopœias, they are not pure chemical compounds, but merely compounds of the oxides or the alkaloids, as the case may be, with oleic acid dissolved in a great excess of the latter.

Oleates may be made either by direct combination of the ingredients or by double decomposition. When made by the latter method, a good quality of oleic acid should be treated with the proper quantity of solution of sodium hydroxide, to saponify it, any excess of the alkali being neutralized with a little tartaric acid. This soap solution is preferably used diluted.

J. M. Good, in making the oleates of the alkaloids, proposes the use of sufficient oleic acid to dissolve the alkaloid and then diluting the solution with a bland fixed oil, such as almond oil. (*Proc. Missouri Pharm. Association*, 1891, p. 65.)

The *medicinal properties* of the oleates are, of course, dependent upon the base, so that these preparations may be considered the equivalents of the corresponding ointments, over which, however, they have certain advantages. They are much cleaner and more elegantin appearance. They seem to be more irritating than the ointments, and, unless diluted with an equal bulk of cottonseed, olive, or other bland oil, are, when applied with friction, likely to provoke a cutaneous eruption or even pustulation. Marshall recommends that they be applied with a brush, or gently spread over the part with the finger.

OLEATUM HYDRARGYRI. U. S. (Br.)

OLEATE OF MERCURY Oleat. Hydrarg.

(ō-lē-ā'tŭm hȳ-drär'gy-rī)

Hydrargyrum Oleatum, *Br.;* Mercuric Oleate; Hydrargyrum Oleicum; Oléate de Mercure, *Fr.;* Oelsaures Quecksilber, Quecksilberoleat, Mercurioleat, *G.*

* "Yellow Mercuric Oxide, in very fine powder, *twenty-five grammes* [or 386 grains]; Alcohol, *twenty mils* [or 325 minims]; Oleic Acid, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the yellow mercuric oxide with the alcohol in a tared dish, add *seventy-five grammes* [or 2 ounces av., 282 grains] of oleic acid, warm the mixture to a temperature not exceeding 50° C. (122° F.), stir constantly for five minutes and then continue the heat, stirring frequently, until the alcohol is expelled and the mercuric oxide is dissolved. Now add sufficient oleic acid to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains] and mix thoroughly. Preserve Oleate of Mercury in tightly-closed containers protected from strong light and do not dispense it if globules of mercury are visible at the bottom of the container. In the preparation of this Oleate avoid all contact with metallic utensils." *U. S.*

"Yellow Mercuric Oxide, 20 *grammes;* Liquid Paraffin, 5 *grammes;* Oleic Acid, 75 *grammes.* Triturate the Mercuric Oxide with the Liquid Paraffin until it is thoroughly subdivided; add the Oleic Acid with vigorous stirring. Heat the mixture to 50° C. (122° F.) triturating occasionally until combination is effected, and, when cool, a yellowish unctuous preparation is obtained." *Br.*

This oleate is now made with 25 per cent. of mercuric oxide; that of the British Pharm. (1914) contains 20 per cent. Water was used in this oleate in order to facilitate combination in the U. S. P. VIII, but it was replaced by alcohol in the U. S. P. IX.

This preparation was introduced by Marshall in 1872. If made from oleic acid which has been purified from the usual contaminations (palmitic and stearic acids), it is a clear yellowish liquid of a thick consistence and having the peculiar odor of oleic acid. As usually seen, however, it is of the consistence and appearance of petrolatum, due to the presence of small quantities of mercuric palmitate and stearate. (See *Acidum Oleicum,* p. 52.) The formula of a normal oleate of mercury would be $(C_{18}H_{33}O_2)_2Hg$. For its formation we should reckon for every 25 parts of mercuric oxide from 65 to 66 parts of oleic acid. Free oleic acid is intentionally present in this U. S. preparation, which is known frequently as "25 per cent. oleate of mercury." In making this preparation, care must be exercised in the selection of the oleic acid, and to avoid exceeding the degree of heat directed in the official process; indeed, our experience has been that it keeps better if made by the cold process—*i.e.,* by simply mixing the freshly precipitated yellow oxide with the oleic acid, and allowing them to stand at ordinary temperatures until the precipitate has dissolved. The British preparation (1898) was modelled after Shoemaker's process, but in the Br. Pharm., 1914, the mercuric oxide is triturated with liquid paraffin. The precipitated mercuric oleate is difficult to free from water, and is prone to change. In time, even with the best oleic acid that can be procured, some decomposition will take place, and metallic mercury will be found at the bottom of the containing bottle. The rapidity of the change will be in proportion to the impurities in the oleic acid and the degree of heat employed. Beringer's process, by the double decomposition of potassium oleate and mercuric nitrate, is commended by Edel. (See *West. Drug.,* 1894, 85.)

Uses.—This preparation may often be substituted with advantage for mercurial ointment, which it closely resembles in its medicinal properties, except that it is more readily absorbed, and therefore more effective. It has been especially commended by Marshall in cases of *chronically inflamed joints,* and in *hordeolum, indurations after abscesses,* and various other forms of superficial local inflammations of a slow type; also in *sycosis, tinea, psoriasis, eczema,* and as a constitutional alterative in *hereditary syphilis.*

Dose, one-half to two drachms (2–8 Gm.) applied externally.

OLEORESINA ASPIDII. U. S. (Br.)

OLEORESIN OF ASPIDIUM Oleores. Aspid. [Oleoresin of Male Fern]

(ō-lē-ō-rĕs'ĭ-nă ăs-pĭd'ĭ-ī)

"Liquid Extract of Male Fern contains in 100 grammes not less than 20 grammes of filicin." *Br.*

Extractum Filicis Liquidum, *Br.;* Oleoresina Filicis, *Pharm.* 1870; Liquid Extract of Male Fern, Oil of Fern; Oleum Filicis Maris; Extrait de Fougère Mâle, *Fr. Cod.;* Extractum Filicis, *P. G.;* Farnextrakt, Wurmfarnextrakt, Wurmfarnöl, *G.;* Estratto de felce maschio etero, *It.;* Extracto etereo de helecho macho, *Sp.*

* "Aspidium, recently reduced to No. 40 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Place the aspidium in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered

bottle. Note: Oleoresin of Aspidium, on standing, usually deposits a granular, crystalline substance. This should be thoroughly mixed with the liquid portion before use." *U. S.*

"Male Fern, in No. 20 powder, 1000 *grammes;* Ether, *a sufficient quantity.* Exhaust the Male Fern by percolation with the Ether; from the clear percolate recover the ether by distillation and finally evaporate on a water-bath until an oily extract remains. Specific gravity not less than 1.000. *Refractive index* at 40° C. (104° F.) not less than 1.490. Contains in 100 grammes not less than 20 grammes of filicin as determined by the following process:—Dissolve 5 grammes of the Liquid Extract in 40 millilitres of *ether,* transfer to a separator, add 100 grammes of *solution of barium hydroxide* and shake vigorously and continuously for five minutes. Allow the liquids to separate and filter off 86 grammes of the aqueous liquid. Acidify this with *hydrochloric acid* and extract with three successive portions of 30, 20, and 15 millilitres of *ether.* Filter the mixed ethereal solutions, wash the filter paper with *ether,* evaporate, dry the residue at 100° C. (212° F.) and weigh. It weighs not less than 0.8 gramme, equivalent to not less than 20 grammes of filicin in 100 grammes of the Liquid Extract. This Liquid Extract contains not less than 20 per cent. of filicin." *Br.*

This is the only preparation of male fern which should be used; in its making aspidium which is green in color and recently collected should be employed. It is a thick, dark green liquid, usually containing a granular deposit of crystalline *filicic anhydride,* often erroneously called *filicin* or *filicic acid,* which is regarded as the active ingredient and should not be separated. For a method of determining the percentage of filicic acid by Daccomo and Scoccianti, see *Ph. Centralh.,* 1896, 208. Wm. G. Greenawalt found both the liquid and the sediment effective tenicides, the sediment somewhat the more active. It has the odor of fern, and a nauseous, bitterish, somewhat acrid taste. According to Hayes, when an absolutely dry root and an anhydrous ether (containing but little alcohol) of a specific gravity below 0.728 are used, the oleoresin remains clear. Kramer states that a very active extract of male fern may be prepared by exhausting with ether the fresh juicy rhizomes collected in May or October freed from scales and cut into small pieces. The ethereal tincture should be kept in a cool place until wanted, when the necessary quantity should be converted into extract. One dose, two to four drachms, of such an extract is said to have always produced satisfactory results. (*Ph. Cb.,* xxv, 578.) Oleoresin of male fern is sometimes found in the market containing noticeable proportions of copper, and in many cases it is colored green artificially.

For therapeutic properties of this oleoresin, see *Aspidium.*

Dose, from one-half to one fluidrachm (1.8–3.75 mils), administered in emulsion.

OLEORESINA CAPSICI. U. S.

OLEORESIN OF CAPSICUM Oleores. Capsic.

(ō-lę-ō-rĕs'ĭ-nȧ kăp'sĭ-cī)

Oléorésine (Extrait éthéré) de Capsique, *Fr.;* Spanisch-pfeffer-Oelharz, Aetherisches Spanischpfeffer-extrakt, *G.*

* "Capsicum, in No. 40 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Place the capsicum in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the percolate measures *eight hundred mils* [or 27 fluidounces, 24 minims]. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place. Then pour off the liquid portion, transfer the remainder to a glass funnel provided with a pledget of cotton, and, when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

One of the active principles of capsicum, called *capsaicin,* $C_9H_{14}O_2$, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined. Another principle, even still more pungent than *capsaicin,* is *capsacutin* which is also extracted by the official solvent in making this oleoresin. (See *Capsicum.*) After the concentration of the acetone solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable, however, of being dropped, of a dark reddish-brown color, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odor of capsicum, but to the taste is intensely pungent. W. C. Alpers found a capsicum which yielded 16 per cent. of oleoresin; the statement has been frequently made that 5 per cent. is the usual yield. (*M. R.,* 1896, 593.) It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of *gastric insensibility* and excessive *flatulence.* One drop given three times a day has produced cystic irritation and strangury. It may be used also as a powerful rubefacient, in strengths of from one to two per cent., diluted with olive oil or soap liniment.

Dose, from one-fourth to one grain (0.015–0.065 Gm.).

Off. Prep.—Emplastrum Capsici, *U. S.*

OLEORESINA CUBEBÆ. U. S.

OLEORESIN OF CUBEB Oleores. Cubeb.

(ō-lę-ō-rĕs'ĭ-nȧ cū-bē'bæ)

Extractum Cubebæ Æthereum; Oléorésine de Cubèbe, *Fr.;* Extractum Cubebarum, *P. G.;* Aetherisches Kubebenextrakt, Kubebenextrakt, *G.*

* "Cubeb, in No. 30 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Alco-

hol, *a sufficient quantity.* Place the Cubeb in a cylindrical glass percolator, pack the powder firmly, and percolate slowly with alcohol, added in successive portions, until the drug is exhausted. Recover the greater part of the alcohol from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining alcohol to evaporate in a warm place, stirring frequently. Keep the Oleoresin in a well-stoppered bottle.

"NOTE: Oleoresin of Cubeb, after standing for some time, deposits a waxy and crystalline precipitate, which should be rejected, the liquid portion only being used." *U. S.*

A change was made in the menstruum for this oleoresin in the U. S. P. (8th Rev.) alcohol now being used instead of ether or acetone. The use of alcohol was suggested by E. R. Squibb. This oleoresin consists mainly of the volatile oil and resin, with a portion of the cubebin and waxy matter of the cubeb. The consistence differs according to the character of the cubeb employed, its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The color is usually blackish brown, with more or less of a greenish hue, according to the quantity of chlorophyll present, which varies with the character of the cubeb and with that of the menstruum, pure ether extracting more of the green coloring matter, while alcohol extracts the brown; unripe fruit or berries yield more chlorophyll than do the ripe fruit. Cubeb yields from one-eighth to one-fifth of its weight of the oleoresin. The preparation deposits waxy matter and crystals of cubebin on standing, which should be separated and discarded; its efficacy is not impaired on this account. It was first introduced into use by Procter. (*A. J. P.*, xviii, 168.)

From carefully conducted experiments by F. V. Heydenreich, it would appear that, of the various constituents of cubeb contained in the official oleoresin, the cubebin has no perceptible effect in the dose of the medicine ordinarily given, that the volatile oil is simply stimulant and carminative, and, finally, that the soft resin has all the diuretic properties of the cubeb. Of the last-mentioned ingredient, twenty grains (1.3 Gm.) given every two hours until five doses were taken considerably increased the secretion of urine, producing at the same time a slight burning sensation in the passage, which ceased with the diuretic action. Pushed beyond this amount, it occasioned severe irritation of the urinary passages, with some fever.

This oleoresin, as it occurs in the market, often has a thin consistence. In one specimen three-eighths of its weight were lost in a short time by the spontaneous evaporation of the ether improperly left in the product.

Dose, from five to ten minims (0.3–0.6 mil), given suspended in water, or mixed with powdered sugar.

Off. Prep.—Trochisci Cubebæ, *U. S.*

OLEORESINA PETROSELINI. U. S.

OLEORESIN OF PARSLEY FRUIT Oleores. Petrosel. [Liquid Apiol]

(ō-lē-ō-rĕs'ĭ-nă pĕ-trŏ-sĕ-lī'nī)

Apiol, Oil of Parsley Seed.

* "Parsley Fruit, in No. 60 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity.* Place the parsley fruit in a cylindrical glass percolator provided with a stop-cock and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly and percolate slowly with ether, added in successive portions until the drug is exhausted. Recover the greater portion of the ether by distillation on a water bath, and, having transferred the residue to a dish, remove the remaining ether by spontaneous evaporation in a warm place, stirring frequently. Allow the Oleoresin to stand without agitation for four or five days, decant the clear liquid portion from any solid residue, and preserve it in well-stoppered bottles." *U. S.*

This oleoresin is commonly called "liquid apiol." The official process should be strictly followed as cases are on record where commercial gasoline or benzin has been used as the menstruum and the percolate evaporated spontaneously, whereupon a yield of as much as 50 per cent. of a non-volatile, oily liquid was obtained which consisted chiefly of the non-volatile portions from the gasoline. Such a procedure cannot be too severely condemned.

According to L. Wolff (*A. J. P.*, 1877, 2), commercial *apiol* is merely the oleoresin; he proposes a very simple process for true apiol. Powdered parsley seed is exhausted with petroleum benzin, and the liquid is spontaneously evaporated; the residue is a mixture of fixed oil, wax, and apiol; the apiol alone being soluble in alcohol can easily be separated by repeated washings with strong alcohol; the washings evaporated over a water bath at a gentle heat leave as a residue "true apiol." L. Ough (*C. D.*, 1894, 17) obtains apiol by percolating freshly powdered parsley seeds with alcohol, recovering the alcohol from the percolate by distillation, and separating the oily residue from the deposited waxy solid.

Ciamician and Silber (*Ph. Post,* 1888, 391) have investigated apiol, and state that the pure substance occurs in white crystals having the composition $C_{12}H_{14}O_4$, melting at 30° C. (86° F.), and boiling at 294° C. (561° F.). *Isapiol, apiolic acid, apiolaldehyde,* and *apion* are decomposition products. They state that isapiol has physiological properties resembling those of pure apiol.

H. C. Whitney (*N. R.*, January, 1880) proposed to change the name of commercial apiol, and call it *oil of parsley seed.* He believed that the volatile oil of parsley seed is the active and emmenagogue principle, and obtained it by distilling the freshly powdered seed with salt water. The yield is 4.27 per cent. of an oil which corresponded closely with Joret and Homolle's apiol.

Von Gerichten (*Ber. d. Chem. Ges.*, 16, 17) obtained besides the peculiar terpene, *parsley camphor*, which he thinks is alone entitled to the name of apiol. He gives its melting point as 30° C. (86° F.), boiling point 300° C. (572° F.), and sp. gr. 1.015.

Parsley camphor has been given the formula CH_2: $CH.CH_2.C_6H(OCH_3)_2$: O_2: $CH_2.CH$.—It may be prepared by extracting the oleoresin of parsley seed with ether and subsequent purification. It crystallizes in long needles of a slight parsley odor—insoluble in water, but readily soluble in alcohol. With strong sulphuric acid it gives a blood-red color.

Uses.—The oleoresin of parsley contains a number of bodies of considerable physiological power. The most important of these are crystalline apiol, white apioline, and myristicin. According to the experiments of Lutz (*Bull. Sci. Pharm.*, 1910, xvii, p. 1) the actions of these substances are similar in kind. They produce marked slowing of the pulse with fall of the blood pressure, tremors, and weakness of the extremities, followed by paralysis with epileptiform convulsions and gasping respirations. After death there was found marked congestion in the lungs and in the pelvic organs. Rimini and Dilitala (*Archiv. di. Farmacologia e. Terap.*, 1908, xiv) have shown that apiol produces in the cat fatty degeneration of the liver of the same type as is caused by myristicin (see page 777). They also noted that it had a direct weakening action on the voluntary muscles.

Oleoresin of parsley and other principles derived from this plant have been used in various uterine disorders, especially in *dysmenorrhea*. Our knowledge of its physiological action, however, furnishes no ground for attributing to it valuable properties in this or any other disease. The congestion in the pelvic organs found after death from this drug, may easily be attributed to the asphyxial nature of the poisoning. There is no evidence that in quantities approaching those used in medicine it has any influence of any kind upon the uterus. Glatard (*Journ. de Med. et Chir. Prat.*, 1910, p. 674) reports a case of apiol poisoning in a pregnant woman who took six grammes in a period of forty-eight hours. There was vertigo, nausea and vomiting, urticaria, liver swollen and painful, mild icterus, urine scanty and high colored, but free from albumen; pregnancy was not interrupted. Sardou (*A. G. M.*, 1906) recommends apiolin as an antispasmodic in *intestinal colic*.

Dose, five to fifteen minims (0.3–0.9 mil).

OLEORESINA PIPERIS. U. S.

OLEORESIN OF PEPPER Oleores. Piper.

(ō-lē-ō-rĕs'ĭ-nȧ pĭp'ẹ-rĭs)

Extractum Piperis Fluidum, *U. S.* 1850; Fluid Extract of Black Pepper; Oléorésine de Poivre noir, *Fr.*; Aetherisches Pfefferextrakt, *G.*

* "Pepper, in No. 40 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity*. Place the pepper in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, set this aside in a warm place until the remaining ether has evaporated, and the deposition of piperine has ceased. Lastly, separate the Oleoresin from the piperine by straining through purified cotton. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

A substance has long been in use under the name of *oil of black pepper*, consisting mainly of the volatile oil, fixed oil, and resin of the pepper, and belonging, therefore, to the oleoresins. As usually found, it is almost black and of a thick consistence, and is a residue of the process for preparing piperine. The official oleoresin made with ether has the same general character, but is more fluid and of more uniform strength, and should, therefore, be preferred. It contains almost all the volatile oil and acrid resin of black pepper, with little of the piperine, and, as the last-mentioned principle, when quite pure, is of doubtful efficacy, the oleoresin may be considered as representing the virtues of the fruit. The color is greener than that of the common oil of black pepper, and not so dark, owing to the fact that the solvent dissolves the green more readily than the brown coloring matter. A pound of black pepper yields about six drachms of the oleoresin.

Dose, from one-fourth to one minim (0.015–0.06 mil), in emulsion or pill.

OLEORESINA ZINGIBERIS. U. S.

OLEORESIN OF GINGER Oleores. Zingib.

(ō-lẹ-ō-rĕs'ĭ-nȧ zĭn-gĭb'ẹ-rĭs)

Extractum Zingiberis Æthereum; Oléorésine (Piperoide) de Gingembre, *Fr.*; Zingiberin, Aetherisches Ingwerextrakt, *G.*

* "Ginger, in No. 60 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Ether, *a sufficient quantity*. Place the ginger in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

In the U. S. formula of 1870 for this preparation alcohol was used in connection with ether, on the score of economy: it was added in order to displace the ether and thus save an unnecessary expenditure of the more costly fluid. A little of the alcohol mixed with the ether at their surface of contact. In the present

process both ether and alcohol have been replaced by the solvent, ether. The whole of the virtues of the root are extracted in this preparation, as the residuary ginger is nearly or quite tasteless. The oleoresin constitutes about 5 per cent. of the dried root. It is the *piperoid of ginger* of Beral. (Soubeiran's *Traité de Pharm.*, i, 371.) It is a clear, dark-brown liquid, of a thick consistence (though capable of being dropped), with the flavor of ginger, and very pungent.

The oleoresin of ginger is a useful stimulant in *alcoholic gastritis, chronic serous diarrheas* and other atonic conditions of the alimentary canal.

Dose, one-half to one minim (0.03–0.06 mil), well diluted.

OLEORESINÆ

OLEORESINS

(ō-lę-ō-rĕs'ĭ-næ)

Oléo-résines, Extraits éthérés, *Fr.*; Oelharze, Aetherische Extrakte, *G.*

The oleoresins, as a class of preparations, were introduced into the U. S. Pharmacopœia at the revision of 1860, having been previously classed with the Fluidextracts. Their peculiarity is that they consist of principles which, when extracted by means of ether, alcohol, or acetone, retain a liquid or semi-liquid state upon the evaporation of the menstruum, and at the same time have the property of self-preservation, differing from the fluidextracts in not having a definite relation of strength to the drug. They consist chiefly, as their name implies, of oil, either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the drug with acetone, alcohol or ether by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of the solvent, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not to continue the heat necessary for the recovery of the solvent by distillation until the whole of the solvent is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence in every instance the last portions of the menstruum are allowed to separate by spontaneous evaporation. Petroleum benzin has been proposed as a substitute for other solvents in these preparations, but should not be permitted to supersede them until officially sanctioned. It is difficult, if not impossible, to remove the last traces of this solvent without loss of volatile oil. Acetone replaced ether in most of the formulas of the U. S. P. VIII on account of economy, but as ether is again the cheaper solvent because of the use of denatured alcohol in its manufacture, it is again officially directed in the U. S. P. IX. Oleoresin of cubeb is made with alcohol.

OLEUM ABIETIS. Br.

OIL OF SIBERIAN FIR [Oil of Pine]

(ō'lę-ŭm ă-bī-ē'tĭs)

"Oil of Siberian Fir is the oil distilled from the fresh leaves of Abies sibirica, *Ledeb.*" *Br.*

"Colorless or nearly so. Aromatic odor; taste pungent. Specific gravity 0.900 to 0.920; *optical rotation* —32° to —42°; *refractive index* at 25° C. (77° F.) about 1.474. Contains from 30 to 40 per cent. of *esters*, calculated as bornyl acetate, $C_{10}H_{17}C_2H_3O_2$." *Br.*

This is practically the same in its properties and uses as pine needle oil. (See *Oleum Pini Pumilionis.*)

OLEUM AJOWAN. Br.

AJOWAN OIL [Ptychotis Oil]

(ō'lę-ŭm ă'jō-wän)

"Ajowan Oil is the oil distilled from the fruit of Carum Copticum, *Benth. and Hook. f.*" *Br.*

Under the name of *ajowan, ajwain, ajwan,* and other vernacular appellations, the fruit of the *Carum Ajowan* Bentley (*C. Copticum* Benth. and Hook. f.) are largely used in India as an aromatic. They resemble in size the fruits of the ordinary parsley and are of a grayish-brown color and have a tubercular surface with five prominent ridges to each mericarp. The odor and taste resemble that of thyme. These fruits yield from 4 to 6 per cent. of an agreeably aromatic volatile oil. Ajowan oil is "colorless, with an odor and taste resembling thyme. Specific gravity 0.910 to 0.930. *Optical rotation* +1° to +2°. When 10 millilitres with 100 millilitres of *solution of sodium hydroxide* in a flask with a narrow graduated neck are heated on a water-bath, well shaken, and allowed to stand, the uncombined oil, cooled to 15.5° C. (60° F.), measures not more than 6 millilitres (presence of not less than 40 per cent. of thymol)." *Br.*

This oil, besides containing thymol, contains a terpene and also the cyclic hydrocarbon cymene.

The oil of ajowan is one of the most important commercial sources of thymol. Its medicinal virtues are due entirely to this ingredient.

Dose, one-half to five minims (0.03–0.3 mil).

OLEUM AMYGDALÆ AMARÆ. U. S.

OIL OF BITTER ALMOND Ol. Amygd. Amar. [Bitter Almond Oil]

(ō'lę-ŭm ą-mŭg'dą-læ ą-mă'ræ)

"A volatile oil obtained by maceration and distillation from the ripe kernels of *Prunus Amygdalus amara* DeCandolle (Fam. *Rosaceæ*), and from other kernels containing amygdalin. It yields not less than 85 per cent. of benzaldehyde [C_7H_6O] and not less than 2 per cent. nor more than 4 per cent. of hydrocyanic acid [HCN]. The botanical source from which it is derived must be stated on the label. Preserve it in small, well-stoppered, completely filled, amber-colored bottles protected from light and

air. Oil showing crystals of benzoic acid must not be dispensed.

"NOTE: This Oil is intended for medicinal use; it must not be used for flavoring foods." *U. S.*

Oleum Amygdalarum (Amararum) Æthereum; Oleum Amygdalæ Volatile; Volatile Oil of Almond; Huile volatile d'Amande amère, *Fr. Cod.*; Essence d'Amandes amères, *Fr.*; Bittermandelöl, *G.*; Esencia de almendras amargas, *Sp.*

When bitter almonds are expressed, they yield a bland fixed oil, and the residuary cake, reduced to powder by grinding, and submitted to distillation with water, yields *oil of bitter almond.* This does not pre-exist in the almond, but is produced by the action of water upon the amygdalin contained in it, through the intervention of an enzyme called *emulsin* (see *Amygdala Amara*), according to the reaction:

$$C_{20}H_{27}NO_{11} + 2H_2O = C_7H_6O + 2C_6H_{12}O_6 + HCN$$

It is obtained also by the distillation of the leaves of the cherry-laurel, by the bark of the wild cherry, and of various products of the genera *Amygdalus, Cerasus, Prunus,* etc. Whipple obtained, upon an average, from the ground bitter almond cake, 1.35 per cent. of the oil. (*P. J.*, x, 297.) Pettenkofer has ascertained that the yield is greater if the cake be macerated in water for forty-eight hours before being submitted to distillation. (*J. P. C.*, May, 1862, p. 432.) It is sometimes produced from peach kernels. Schimmel's Report for April, 1914, refers to the fact that the sole source of the oil at that time was apricot kernels.

Oil of bitter almond has a yellowish color, a bitter, acrid, burning taste, and the odor of the kernels in a high degree. It is heavier than water, soluble in alcohol and ether, according to Flückiger soluble in 300 parts of hot or cold water, and deposits, upon standing, a white crystalline substance consisting chiefly of benzoic acid. It is officially described as "a clear, colorless or yellow, strongly refractive liquid, having the characteristic odor and taste of benzaldehyde. It is slightly soluble in water and soluble in all proportions in alcohol or ether. It dissolves, forming a clear solution, in 2 volumes of 70 per cent. alcohol. Specific gravity: 1.038 to 1.060 at 25° C. (77° F.). Refractive index: 1.5428 to 1.5439 at 20° C. (68° F.) (see Part III, Test No. 22). It is optically inactive or dextrorotatory, not exceeding +0° 10′ in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). When first prepared, the Oil is neutral to litmus paper, but afterwards develops an acid reaction due to the formation of benzoic acid. It does not respond to the Test for heavy metals in volatile oils (see Part III, Test No. 3). Hold the looped end of a piece of clean copper wire in a non-luminous flame until it glows without coloring the flame green, cool the wire, dip the loop into Oil of Bitter Almond, ignite the latter and hold it so that the liquid burns outside of the non-luminous flame. On slowly bringing the flame from the burning Oil of Bitter Almond on the loop in contact with the lower outer edge of the non-luminous flame, no green tinge is discernible (*chlorinated products*). Add 10 drops of the Oil to a little alcohol, then add a small amount of zinc dust and 2 mils of acetic acid and boil the mixture for a short time; no odor of phenylisocyanide develops after rendering it strongly alkaline with potassium hydroxide T.S., adding a few drops of chloroform and heating (*nitrobenzene*)." *U. S.*

Besides the peculiar volatile oil, it contains also hydrocyanic acid, with usually a small proportion of benzoic acid produced by oxidation of the aldehyde. It may be obtained pure by agitating it strongly with calcium hydroxide and a solution of ferrous chloride, submitting the mixture to distillation, and drying the oil which comes over by digestion with calcium chloride. George Whipple states that if crude oil be redistilled into a solution of silver nitrate, and again distilled from a fresh solution of the same salt, it is obtained entirely free from hydrocyanic acid, which reacts with the silver and remains behind as silver cyanide. (See *A. J. P.*, xxvi, 348.) Thus purified, it is colorless, but still retains its peculiar odor, with a burning, aromatic taste, and is destitute of those poisonous properties of the crude oil which are dependent on hydrocyanic acid. The odor of the oil of bitter almond has been erroneously ascribed to that acid, which, on examination, will be found to have a different and more feeble odor. Like most other volatile oils, this may produce deleterious effects if taken very largely. Hippuric acid is found in the urine of animals to which the oil has been given freely. The sp. gr. of the crude oil varies from 1.05[illegible] to 1.082, and is said to be greater when the oil is distilled from salt water than when distilled by the ordinary mode. That of the purified oil is 1.060, and its boiling point 180° C. (356° F.). It is *benzoic aldehyde,* $C_6H_5.COH$, which may also be produced by the action of oxidizing agents upon benzyl alcohol, $C_6H_5.CH_2OH$, and yields itself, when oxidized, benzoic acid, $C_6H_5.COOH$. The benzoic acid which the oil of bitter almond deposits on standing does not pre-exist in it, but results from the absorption of oxygen, as just stated. The U. S. P. IX provides for an assay for benzaldehyde and also one for hydrocyanic acid, see page 747.

Schimmel & Co. (*Semi-Annual Report,* April, 1893) state that an oil of high specific gravity should be carefully examined for benzo-nitrile, C_6H_5CN, which may form by condensation from benzaldehyde and hydrocyanic acid, and when distilled even *in vacuo* will decompose into the same components.

Benzoic aldehyde is now made synthetically from toluene, C_7H_8. (See *Benzaldehydum.*) By the action of chlorine upon the hot hydrocarbon, benzyl chloride, $C_6H_5CH_2Cl$, results, and this yields benzoic aldehyde on distillation with lead nitrate and water in an atmosphere of carbon dioxide gas. More generally, however, *benzal chloride,* $C_6H_5CHCl_2$, is taken, as this, when heated under pressure with water or sulphuric

acid, readily yields the benzaldehyde. The product is purified by conversion into the acid sulphite compound. Lippmann and Hawliczek have made exhaustive researches on the identity of the artificial with the natural oil of bitter almond, and have found the two oils absolutely identical, physically as well as chemically. At the present time benzaldehyde, or synthetic oil of bitter almond, is very largely used, its chief advantages being uniformity of composition and absence of hydrocyanic acid. To prevent the formation of benzoic acid in oil of bitter almond, Schimmel & Co. recommend the addition of 10 per cent. of alcohol to the oil.

If sulphuric acid produce with the oil a bright-red instead of a brownish-red color, the oil has probably been distilled with salt water, in which case it is prone, according to Ferris, to deposit a blood-red substance, occasionally complained of by druggists.

Wm. A. Tilden has found that the introduction of a little fused calcium chloride into purified oil of bitter almond contributes to its preservation, probably by the absorption of the last traces of water contained in it. Of two specimens of the oil, which had been set aside for two years, one without addition, the other containing a fragment of the fused chloride, the former was found filled with crystals of benzoic acid, and the latter was perfectly free from crystalline deposit and quite fluid. (*P. J.*, 2d ser., 1866, viii, 325.)

Nitrobenzene was at one time a frequent adulterant of oil of bitter almond. It may best be detected by the U. S. P. IX test given above, for additional tests see U.S.D., 19th ed., p. 830–831.

Hager's test may be used quantitatively for the estimation of the amount of nitrobenzene present. Oil of bitter almond requires for solution sixteen to seventeen times its volume of 45 per cent. alcohol. Two mils of the oil are agitated with 34 mils of the 45 per cent. alcohol, and the mixture set aside. After the lapse of a day, the nitrobenzene (all but a trace which remains in solution) will be found collected at the bottom. An important indication of the presence of a sophistication is the cloudiness produced at the first moment. (*N. R.*, Oct., 1880.)

Assay for Benzaldehyde.—"Dissolve about 3 mils of freshly redistilled phenyl hydrazine in 60 mils of alcohol and titrate 25 mils of this solution, which must always be freshly prepared, with half-normal hydrochloric acid V.S., using methyl orange T.S. as indicator. To about 1 Gm. of the Oil of Bitter Almond, accurately weighed, add 25 mils of the phenylhydrazine solution just prepared and allow it to stand for thirty minutes. Add a drop of methyl orange T.S., and acidify the mixture by adding a measured excess of half-normal hydrochloric acid V.S. Filter the mixture and wash the precipitate with small portions of distilled water until the washings cease to redden blue litmus paper. Then titrate the excess of hydrochloric acid in the filtrate with half-normal potassium hydroxide V.S. and subtract the number of mils of the half-normal hydrochloric acid V.S. consumed from the number of mils of the half-normal hydrochloric acid V.S. used in titrating the 25 mils of phenylhydrazine solution; the difference multiplied by 0.053 gives the weight of benzaldehyde." *U. S.*

Assay for Hydrocyanic Acid.—"Dissolve 15 Gm. of crystallized magnesium sulphate in enough distilled water to measure 100 mils, add 5 mils of this solution to 40 mils of distilled water, then add 5 mils of half-normal sodium hydroxide V.S. and two drops of potassium chromate T.S., and titrate the solution with tenth-normal silver nitrate V.S. to the production of a permanent reddish tint. Pour this mixture into a 100 mil flask containing about 1 Gm. of Oil of Bitter Almond, accurately weighed, mix well and titrate again with tenth-normal silver nitrate V.S. until a red tint, which does not disappear on shaking, is reproduced. Conduct this titration as rapidly as possible. One mil of tenth-normal silver nitrate V.S. corresponds to 0.0027 Gm. of hydrocyanic acid. One gramme of the Oil corresponds to not less than 7.4 mils nor more than 14.8 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—The unpurified volatile oil of bitter almond, which is the product directed by the Pharmacopœia, acts physiologically like hydrocyanic acid. Death is said to have occurred in a man ten minutes after taking two fluidrachms (7.5 mils) of the oil. It might be substituted with advantage for medicinal hydrocyanic acid, if it always contained a uniform percentage of the acid, as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, provided the oil be preserved in well-stoppered bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22.5 parts of Prussian blue, but the proportion is not constant, varying, according to Groves, from 8 to 12.5 per cent., the U. S. official standard is, however, not less than 2 per cent. and not more than 4 per cent. It has been employed externally, dissolved in water in the proportion of one minim (0.06 mil) to a fluidounce (30 mils), in *prurigo senilis* and other cases of troublesome *itching*. To facilitate the solution in water, the oil may be previously dissolved in spirit. Oil of bitter almond is sometimes used to conceal the taste of cod liver oil and of castor oil.

Dose, one-fourth to one minim (0.015–0.06 mil).

OLEUM AMYGDALÆ EXPRESSUM. U. S. (Br.)

EXPRESSED OIL OF ALMOND Ol. Amygd. Exp. [Oil of Sweet Almond]

(ō'lē-ŭm ą-mŷg'dą-læ ęx-prĕs'sŭm)

"A fixed oil obtained from the kernels of varieties of *Prunus Amygdalus* Stokes (Fam. *Rosaceæ*). Preserve it in well-closed containers,

in a cool place." *U. S.* "Almond Oil is the oil expressed from the Bitter or Sweet Almond." *Br.*

Oleum Amygdalæ *Br.*; Almond Oil; Oleum Amygdalæ Dulcis, *U. S.* 1860; Oil of Sweet Almond; Huile d'Amande douce, *Fr. Cod.*; Huile d'Amandes, *Fr.*; Oleum Amygdalarum, *P. G.*; Mandelöl, *G.*; Olio di mandorle dolci, *It.*; Aceite de almendras dulces, *Sp.*

This oil is obtained equally pure from sweet and from bitter almonds. In its preparation, the almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then pressed in canvas sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove, previous to expression. The oil is thus obtained free from color, but in no other respect better, while it is more likely to become rancid on keeping. Bitter almonds treated in this way impart an odor of hydrocyanic acid to the oil. Boullay obtained 54 per cent. of oil from sweet almonds. Munch gives 55.4 per cent. as the yield of the former, and 52 per cent. as that of the latter. (*J. P. C.*, 4e sér., iii, 400.) These figures are not realized, however, in the ordinary expression methods. Schaedler (*Technologie der Fette und Oele*, 2te Auf., 532) gives 45 per cent. as the average obtained from the sweet almonds, and 38 per cent. from bitter almonds. Though sometimes expressed in this country from imported almonds, the oil is generally brought from Europe.

Properties.—It is "a clear, pale straw-colored or colorless, oily liquid, almost odorless, and having a bland taste. It is slightly soluble in alcohol, miscible with ether, chloroform, benzene, or petroleum benzin. Specific gravity: 0.910 to 0.915 at 25° C. (77° F.). The oil remains clear at –10° C. (14° F.), and does not congeal until cooled to nearly –20° C. (–4° F.) (*olive or lard oil*). Shake vigorously 2 mils of the Oil with a mixture of 1 mil of fuming nitric acid and 1 mil of water; a whitish mixture is formed, which, after standing for several hours at about 10° C. (50° F.), separates into a solid white or nearly white mass and a slightly colored liquid (*oil of peach or apricot kernels*, yielding a red color, and *sesame or cottonseed oil*, yielding a brown color). Heat 10 mils of the Oil with 15 mils of an aqueous solution of sodium hydroxide (1 in 6) and 30 mils of alcohol on a water bath in a flask having a small funnel inserted in the neck, occasionally agitating the mixture until it becomes clear, then transfer the solution to a shallow dish and evaporate the alcohol on a water bath. The residue, when mixed with 100 mils of distilled water, produces a clear solution (*paraffin oil*). Add an excess of hydrochloric acid to this solution; a layer of oleic acid rises to the surface, which, when separated, washed with warm water and clarified by heating on a water bath, remains clear if cooled to 15° C. (59° F.) (*various foreign oils*). One volume of the oleic acid obtained in the last test, when mixed with 1 volume of alcohol, yields a clear solution, which at 15° C. (59° F.) does not deposit any fatty acids, nor become turbid upon the further addition of 1 volume of alcohol (distinction from *olive, arachis, cottonseed, sesame, or other fixed oils*). Saponification value: not less than 191 nor more than 200 (see Part III, Test No. 9). Iodine value: not less than 93 nor more than 100 (see Part III, Test No. 8)." *U. S.*

"Pale yellow. Nearly inodorous; taste bland and nutty. Specific gravity 0.915 to 0.920. *Saponification value* 188 to 196; *iodine value* 93 to 100; *acid value* not more than 6.0; *refractive index* at 40° C. (104° F.) 1.4624 to 1.4640. Remains clear after exposure for three hours to a temperature of –10° C. (14° F.), and does not congeal till the temperature has been reduced to about –18° C. (–0.4° F.). When 1 millilitre of a freshly prepared mixture of equal parts by weight of *sulphuric acid, fuming nitric acid*, and *water*, kept cool while cautiously mixed, is vigorously shaken with 5 millilitres of the Oil for one minute, a whitish mixture with not more than the very slightest tinge of red or brown is produced; after some hours a white solid, sometimes tinged with green, separates, the lower acid layer remaining colorless (absence of peach oil and apricot oil)." *Br.*

From the statement of Braconnot, it appears to contain 76 per cent. of olein and 24 per cent. of a mixture of palmitin and stearin.

According to H. Hager, the oils expressed from the large sweet and the smaller bitter almonds differ considerably, as shown by the elaidin test,—the former oil congealing rapidly, and almost completely, the latter about twelve hours later, and the smaller the bitter almond has been the more imperfectly the oil congeals. Only about one-third of the bulk congeals when the oil is from the small Oporto almonds.

Oil of almond is said to be sometimes adulterated with poppy seed oil, or other drying oils of less value. This sophistication may be detected, as suggested by Wimmec, by taking advantage of the property, belonging to the olein of the non-drying but not to that of the drying oils, of being converted into solid elaidic acid by the action of nitrous acid. By treating iron filings with nitric acid in a flask, nitrous acid is produced, which is to be conducted into water upon which the suspected oil is placed. If the almond oil contains even a small quantity of poppy seed oil, or other drying oil, this will remain in the form of drops on the surface, while the genuine oil will be converted entirely into crystallized elaidin. (*J. P. C.*, Dec., 1862, p. 500.) Colza oil, another not uncommon adulteration, may be detected, according to Schneider, by the action of silver nitrate. Dissolve the oil in twice its volume of ether, add about 30 drops of concentrated alcoholic solution of the nitrate, shake the mixture, and allow it to stand in the dark. If there be much

colza oil, the lower part of the liquid will become first brown and then black; if but little, the brown color will not appear for twelve hours, but the discoloration will always be obvious on the evaporation of the ether. (*P. J.*, March, 1862.)

J. D. Bieber communicates the following test. Equal weights of pure concentrated sulphuric acid, red fuming nitric acid, and water are mixed, and the mixture allowed to cool. On mixing five parts of the oil with one part of this acid liquid, pure almond oil gives a yellowish-white liquid; oil of peach kernels assumes the red color of peach blossoms, turning to dark orange; benne oil turns pale yellowish red, then dirty orange-red; poppy and walnut oils yield a somewhat whiter liquid than almond oil. This test permits the detection of 5 per cent. of peach kernel and benne oil. Mixed with pure nitric acid, sp. gr. 1.40, almond oil yields a pale-yellowish liquid, peach kernel oil a red, benne oil a yellowish green, afterwards reddish, and poppy and walnut oils a white mixture. It was found that the oil expressed, cold or warm, from either fresh almonds or from such as had been kept up to ten years, gave the same reaction. Most of the commercial oil was found to be adulterated with the oil of either peach kernels or benne seed. (*A. J. P.*, Dec., 1877.)

Oil of almond may be used for the same purposes as is olive oil, and, when suspended in water by means of mucilage or the yolk of egg and loaf sugar, forms a pleasant emulsion, useful in pulmonary affections attended with *cough*.

Dose, one fluidrachm to one fluidounce (3.75–30 mils).

OLEUM ANETHI. Br.

OIL OF DILL

(ō'lē-ŭm ą-nē'thī)

"Oil of Dill is the oil distilled from Dill Fruit." *Br.*

Huile volatile d'Aneth, Essence d'Aneth, *Fr.*; Dill, Dillöl, *G.*

Oil of dill is of a pale yellow color, with the odor of the fruit, and a hot, sweetish, acrid taste. Its sp. gr. varies between 0.895 and 0.915. The fruit yields about 3.5 per cent. of it. The oil is a mixture of a paraffin hydrocarbon, and 40 to 60 per cent. of *d*-carvone, $C_{10}H_{14}O$, with *d*-limonene, $C_{10}H_{16}$. (See *Oleum Cari.*) Phellandrene is present in the English and Spanish oils, but not to any appreciable extent in the German oil. "Colorless or pale yellow, darkening on keeping. Odor that of Dill Fruit; taste at first sweet and aromatic, but subsequently pungent. Specific gravity 0.900 to 0.915; *optical rotation* +70° to +80°; *refractive index* at 25° C. (77° F.) 1.483 to 1.488. Soluble in 3 parts of *alcohol* (90 per cent.)." *Br.* R. Nietski obtained from dill, the fruit of *Anethum graveolens*, a volatile oil, which commenced to boil at 155° C. (311° F.), the boiling point rising gradually to 260° C. (500° F.). About 10 per cent. of the oil consists of a hydrocarbon, $C_{10}O_{16}$, having the boiling point from 155° to 160° C. (311°–320° F., 60 per cent. boiling at from 170° to 175° C. (338°–347° F.), of the same composition, and 30 per cent. with the boiling point from 225° to 230° C. (437°–446° F.), composition $C_{10}H_{14}O$, and identical with carvol. The odor of the first portion of hydrocarbon is similar to that of turpentine; that of the second portion resembles oil of mace, but when mixed with a little carvol the characteristic dill odor is at once produced. (*A. J. P.*, 1874.) The oil is sometimes used for the preparation of dill water.

***Dose*, from one to three minims** (0.065–0.2 mil).

OLEUM ANISI. U. S., Br.

OIL OF ANISE Ol. Anisi [Anise Oil]

(ō'lē-ŭm ą-nī'sī)

"A volatile oil distilled from the ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbelliferæ*) or from the ripe fruit of *Illicium verum* Hooker filius (Fam. *Magnoliaceæ*). The botanical source from which it is derived must be stated on the label. If solid material has separated, carefully warm the Oil until liquefied, and thoroughly mix it before dispensing. Preserve it in well-stoppered, amber-colored bottles, protected from light." *U. S.* "Oil of Anise is the oil distilled from Anise Fruit; or from the fruit of the star-anise, Illicium verum, *Hook. f.*" *Br.*

Huile volatile d'Anis vert (Badaine), *Fr. Cod.*; Essence d'Anis, *Fr.*; Oleum Anisi, *P. G.*; Anethol, Anisöl, *G.*; Essenza di anice, *It.*; Esencia de anis, *Sp.*

The product of oil from anise is variously stated at from 1.56 to 3.12 per cent. The oil employed in this country is imported. It is colorless or yellowish, with the peculiar odor and taste of the seed. At 10° C. (50° F.) it crystallizes in flat tables, and it does not melt under 16.6° C. (62° F.). Its sp. gr. increases with age, and is variously given at from 0.9768 to 0.9903. It is soluble in all proportions in alcohol of 0.806; but alcohol of 0.840 dissolves at 25° C. (77° F.) only 42 per cent. Ether dissolves oil of anise in all proportions.

Properties.—"Oil of Anise is a colorless or pale yellow, strongly refractive liquid, having the characteristic odor and taste of anise. It is soluble with not more than a slight cloudiness in 3 volumes of 90 per cent. alcohol. Specific gravity: 0.978 to 0.988 at 25° C. (77° F.). Refractive index: 1.544 to 1.560 at 20° C. (68° F.) (see Part III, Test No. 22). The optical rotation varies from +1° to −2° in a 100 mm. tube at 25° C. (77° F.) (*oil of fennel*) (see Part III, Test No. 21). An alcoholic solution prepared as above is neutral to litmus and develops no blue or brownish color upon the addition of a drop of ferric chloride T.S. (*phenols*). It does not respond to the Test for heavy metals in volatile oils (see Part III, Test

No. 3). When tested by the following method, the congealing point of the Oil does not fall below 15° C. (59° F.). Transfer about 10 mils of the Oil to a test tube, place it in a water bath cooled with ice, insert a thermometer at once into the Oil and allow it to remain undisturbed until the temperature has fallen to about 12° C. (53.6° F.). Then induce crystallization either by rubbing the inner wall of the test tube with the thermometer or by the addition of a particle of solid anethol, remove the test tube from the bath and stir during the solidification of the Oil. The highest temperature reached during the crystallization is regarded as the congealing point." *U. S.*

"Colorless or pale yellow. Odor that of Anise Fruit; taste sweet and aromatic. Specific gravity at 20° C. (68° F.) (compared with *water* at 15.5° C. (60° F.)) 0.975 to 0.990; *optical rotation* –2° to + 1°; *refractive index* at 25° C. (77° F.) 1.552 to 1.558. Congeals, when stirred, at about 15.5° C. (60° F.), and does not again liquefy below 17° C. (62.6 ° F.). Not less than 80 per cent. distils between 225° and 235° C. (437° and 455° F.). Soluble in 3 parts of *alcohol* (90 per cent.)." *Br.*

It consists of a small quantity of terpene, $C_{10}H_{16}$, but mainly of *anethol,* parapropenylanisol, $C_6H_4C_3H_5OCH_3$ (about 85 per cent.), which is present, however, in two isomeric modifications, one solid at ordinary temperatures and heavier than water (*solid anethol*), the other liquid and more volatile (*estragol* or *methyl chavicol*). *Anethol,* both in the liquid and in the solid form, is present, and is the chief constituent of the oils of anise, star ansie, and fennel. The solidification test of the U. S. P. IX is based upon the anethol content. By oxidation, by means of nitric acid, or chromic anhydride, the different forms of anethol yield *anisic acid,* $C_8H_8O_3$. Oil of anise, by exposure to air, is oxidized with the formation of anisic aldehyde, acetic aldehyde and anisic acid, and becomes less disposed to congeal.

Star anise oil contains besides anethol, pinene and phellandrene and some samples have been reported as containing safrol which is present to an appreciable extent in the so-called Japanese star anise oil which is from the leaves instead of the fruit. This latter oil contains eugenol as well as much less anethol than the oil from the fruit.

In consequence of its high price, it is frequently adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odor. In one instance as much as 35 per cent. of spermaceti was found. Schimmel & Co. have found fennel stearoptene in commercial oil of anise. (*Ph. Rev.*, 1897, 94.) Procter met with a parcel, of which not less than five-sixths was alcohol. (*A. J. P.*, xxvii, 513.) Its comparative mildness adapts it to infantile cases. Most of the oil of anise of commerce is the *oil of star aniseed* (*Oleum Badiani*, or *Oleum Illicii*). Oil of anise has also been distilled from the sweet cicely, *Osmorrhiza longistylis,* of the United States and Canada. (*Ph. Rund.*, July, 1887.) For description and analysis of Russian oil of anise, see *P. J.*, 1896, 164, also 243. Anisic acid is said to be antiseptic, resembling salicylic acid in its action.

Anethol which was official in the U. S. P. VIII is now recognized by the N. F. The description and tests are as follows: "The methyl ether of para-propenyl phenol [$C_6H_4.C_3H_5.OCH_3 = 148.1$]. It is the main constituent in the oils of anise, star anise, and fennel, and is usually obtained from these by fractioning, chilling and crystallizing. Preserve it in well-stoppered, amber-colored bottles protected from light and air. Anethol is a colorless or faintly yellow, highly refractive liquid at a temperature of 23° C. (73.4° F.) or above, having a sweet taste and the aromatic odor of anise. At from 20° to 21° C. (68°–69.8° F.) it solidifies to a white, glistening, crystalline mass which remelts at from 22° to 23° C. (71.6°–73.4° F.). Anethol is almost insoluble in water, readily soluble in ether or chloroform, and forms a clear solution with two volumes of alcohol. Specific gravity: 0.984 to 0.986 at 25° C. (77° F.). Boiling point: 232° to 234° C. (449.6°–453.2° F.). Refractive index: 1.5 at 20° C. (68° F.). It is optically inactive or shows a deviation of not more than 0.08° in a 100 mm. tube at 25° C. (77° F.), due to slight traces of the oil from which the Anethol has been prepared (if prepared from oil of anise, this deviation will be lævorotatory, if from oil of fennel, dextrorotatory). Shake 10 mils of Anethol with 50 mils of a saturated aqueous solution of sodium bisulphite in a graduated cylinder and allow the mixture to stand for six hours. No appreciable diminution in the volume of Anethol will be observed nor does a crystalline deposit separate (*aldehydes*)." *N. F.*

Uses.—As a flavoring agent the oil of anise rivals any of the aromatic oils in the extent of its applicability. It is especially enjoyed by young children. Therapeutically it is useful to stimulate peristalsis in *colic* and, according to Kobert, also as an *expectorant.* It has also been recommended as a means of destroying body vermin.

Dose, from three to five minims (0.2–0.3 mil).

Off. Prep.—Aqua Anisi, *U. S.;* Elixir Aromaticum (from Spirit), *U. S.;* Spiritus Anisi, *U. S., Br.;* Spiritus Aurantii Compositus, *U. S.*

OLEUM ANTHEMIDIS. Br.

OIL OF CHAMOMILE

(ō'lē-ŭm an-thĕm'ĭ-dīs)

"Oil of Chamomile is the oil distilled from Chamomile Flowers." *Br.*

Oleum Chamomillæ Romanæ; Essence de Camomille romaine, *Fr.;* Römisch-Kamillenöl, *G.*

This oil was introduced into the British Pharmacopœia 1885 with the direction that it should be distilled in Britain. No such restriction is found in the Pharmacopœia of 1898 or 1914. It is seldom prepared in this country. Baumé obtained thirteen drachms of the oil from

eighty-two pounds of the flowers; according to Brande, the average product of 100 pounds is two pounds twelve ounces. It has the peculiar odor of chamomile, with a pungent somewhat aromatic taste.

It is "blue when freshly distilled, but gradually becoming greenish or brownish-yellow under the influence of air and light. Odor that of Chamomile Flowers; taste aromatic, characteristic. Specific gravity 0.905 to 0.915. *Optical rotation* —1° to +3°; *refractive index* at 25° C. (77° F.) about 1.445. Soluble in less than 1 part of *alcohol* (90 per cent.)." *Br.*

The oil was thoroughly investigated in Fittig's laboratory during the years 1878–1879. It was found to consist of a mixture of angelic, butyric, methacrylic, and tiglinic esters of isobutyl, isoamyl, hexyl, and probably a higher alcohol. *Angelic acid* and *tiglinic acid* are isomeric, and have the formula $C_5H_8O_2$. The relative proportions of these two acids varied in different oils. An ester of a lower homologue of angelic acid having the formula $C_4H_6O_2$ was also obtained. Naudin obtained a small amount of a solid paraffin, $C_{18}H_{36}$, melting at 63° C. to 64° C. (145.4°–147.2° F.), to which the name of *"anthemen"* was given. (Gildemeister and Hoffmann, *Aetherische Oele,* p. 881.) An isomer of camphor has also been reported. It has sometimes been employed in spasm of the stomach, and as an adjunct to purgative medicines. Its chief use, however, appears to be as an ingredient of the extract of chamomile of the British Pharmacopœia, to which it is added in order to supply the place of the oil driven off by the heat used in its preparation. This oil must not be confounded with that of *Matricaria Chamomilla,* employed on the continent of Europe under the name of oil of chamomile. (See *Matricaria.*)

Dose, one to three minims (0.06–0.2 mil).

OLEUM ARACHIS. Br.

ARACHIS OIL

(ō'lę-ŭm ą-rā'ȼhĭs)

Arachis Oil is the oil expressed from the seeds of Arachis hypogæa, *Linn.*

Earth-nut Oil, Ground-nut Oil, Pea-nut Oil.

For description of the pea-nut plant (*Arachis hypogæa*) see Part II. The oil consists of the glycerides of four different fatty acids. The chief of these is oleic acid, $C_{18}H_{34}O_2$, with which are associated *linoleic acid,* $C_{18}H_{32}O_2$, *hypogæic acid,* $C_{16}H_{30}O_2$, *arachidic acid,* $C_{20}H_{40}O_2$, and *lignoceric acid,* $C_{24}H_{48}O_2$. It should be obtained by expression without heat. It is usually of a pale yellowish or green color with a faint odor, and a more distinct taste of the nuts, although on rectification a nearly colorless and tasteless oil may be obtained. Upon exposure to the air the oil slowly thickens and becomes rancid. It is soluble in all proportions in ether, chloroform, and petroleum benzin, but insoluble in alcohol.

"Pale yellow or greenish-yellow. Faint, nut-like odor; taste bland, nutty. Specific gravity 0.916 to 0.921; *saponification value* 190 to 196; *iodine value* 83 to 101; *acid value* not more than 6; *refractive index* at 40° C. (104° F.) 1.4628 to 1.4645. When 1 millilitre of the Oil and 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* are boiled for twenty minutes in a flask provided with a reflux condenser, set aside for twenty-four hours at a temperature not exceeding 15.5° C. (60° F.), and afterwards heated on a water-bath for three minutes, the solution deposits crystals on standing. When a mixture of 2 millilitres of the Oil and 1 millilitre of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute, and allowed to stand for five minutes, the acid layer does not become pink (absence of sesame oil). When 2 millilitres of the Oil are mixed with 1 millilitre of *amylic alcohol* and 1 millilitre of a solution (1 in 100) of *precipitated sulphur* in *carbon disulphide,* and the mixture heated in a test-tube immersed in boiling *water,* no red color is developed within fifteen minutes (absence of cotton seed oil)." *Br.*

At 3.3° C. (38° F.) it thickens, solidifies at about –5° C. (23°F.), and at 326.6° C. (620° F.) is decomposed, giving out spontaneously inflammable vapors. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of cerates and ointments, but would not serve as a substitute for olive oil in the preparation of lead plaster. (See *Proc. A. Ph. A.,* 1897, 179.) Its use is permitted, by the British Pharmacopœia, in India, and in the Eastern, African, and Australasian Divisions of the Empire, for making the official Liniments, Ointments, Plasters, and Soaps for which Olive Oil is directed to be used. It is a non-drying oil, and therefore will not answer for painting; but it is enormously used for adulteration (particularly of French olive oils) and for various purposes in the arts, as for lubricating machinery, and in the manufacture of woollen cloths; in lamps it burns with a bright light. It saponifies slowly, but yields an excellent firm, white, and odorless soap.

OLEUM AURANTII. U. S.

OIL OF ORANGE Ol. Aurant. [Oleum Aurantii Corticis, U. S. VIII Orange Oil, Oil of Sweet Orange]

(ō'lę-ŭm âu-răn'tĭ-ī)

"A volatile oil obtained by expression from the fresh peel of sweet orange, *Citrus Aurantium sinensis* Gallesio (Fam. *Rutaceæ*), and its varieties. Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light. Oil of Orange having a terebinthinate odor is not to be dispensed." *U. S.*

Oleum Aurantiorum; Essential Oil of Orange Peel, Essence of Orange; Huile volatile d'Orange, *Fr. Cod.;* Apfelsinenchar-enöl, Pomeranzenschalenöl, *G.;* Essenza di arancio amara, Essenza della corteccia, *It.*

This oil is used only for flavoring purposes, and has been introduced principally because of its employment in elixirs and in *Spiritus Aurantii Compositus.*

Oil of orange is prepared in Calabria and Sicily in three ways: 1, by scraping off the exterior part of the rind and submitting it to expression; 2, by putting the scrapings into hot water, depressing the pulp beneath, and skimming off the oil as it rises; 3, by distillation. The best Sicily orange oil is procured by dexterous compression, within a cask, of the fresh rind by the hand, the oil being driven out in jets. It is sometimes absorbed by a sponge. (*A. J. P.*, 1868.) It is largely made at Messina, and in the south of France. It is also extracted by the écuelle process, and partly from the Bigarade and partly from the sweet or Portugal orange, the scarcely ripe fruit being in either case employed. The oil made from the former is much more valuable than that obtained from the latter, and the two are distinguished in price-currents as *Essence de Bigarade* and *Essence de Portugal.*

Under the name of *Oleum Aurantii Amari* (Oil of Bitter Orange), the National Formulary IV has introduced the oil of bitter orange, which it defines as "a volatile oil obtained by expression from the fresh peel of the bitter orange, *Citrus Aurantium amara* Linné (Fam. *Rutaceæ*). Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light. "Oil of Bitter Orange having a terebinthinate odor is not to be dispensed." *N. F. IV.*

The description is as follows: "Oil of Bitter Orange is a pale yellow liquid, having the characteristic, aromatic odor of the Seville orange, and an aromatic somewhat bitter taste. Soluble in 4 volumes of alcohol, the solution being neutral to litmus paper. Also soluble in all proportions in dehydrated alcohol and in an equal volume of glacial acetic acid. Specific gravity: 0.842 to 0.848 at 25° C. (77° F.). It is dextrorotatory, the angle of rotation varying from +92° to +98°, in a 100 mm. tube, at 25° C. (77° F.). Introduce 50 mils of Oil of Bitter Orange into a 200 mil, three-bulb, fractionating flask. Distil the Oil at the rate of 2 mils per minute until a distillate measuring 5 mils has been collected. The angle of rotation of this distillate is equal to, or only slightly lower than, that of the original Oil." *N. F. IV.*

This oil is supposed to have a more delicate odor than the oil from the sweet orange.

Properties.—Oil of orange peel consists, as has been shown by Wallach, of *d-limonene* to the extent of at least 90 per cent.; of the remainder, about 5 per cent. are the odorous constituents, among which are citral, traces of citronellal, and the methyl ester of *anthranilic acid.* The inner thick part of the rind contains also a bitter principle, called *hesperidin,* discovered by Lebreton in 1828, but more fully studied by Hoffmann (*Ber. d. Chem. Ges.*, 1876, pp. 26, 685). It is best prepared from the unripe bitter orange. Its formula is $C_{22}H_{28}O_{12}$, and it is a glucoside, as is shown by the reaction with diluted sulphuric acid, whereby it is decomposed into *hesperetin,* $C_{16}H_{14}O_6$, and glucose, $C_6H_{12}O_6$.

The U. S. Pharmacopœia describes the oil as "a yellow liquid having the characteristic odor and taste of orange peel. Specific gravity: 0.842 to 0.846 at 25° C. (77° F.). Refractive index: 1.4723 to 1.4737 at 20° C. (68° F.) (see Part III, Test No. 22). Its optical rotation is not less than +94° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). Introduce 50 mils of Oil of Orange into a 200 mil, three-bulb Ladenburg flask of approximately the following dimensions: The lower or main bulb 6 cm. in diameter with the smaller condensing bulbs 3.5 cm., 3.0 cm. and 2.5 cm. in diameter, respectively; with the distance from the bottom of the flask to the side arm 20 cm. Then distil the Oil at the rate of one drop per second until 5 mils has been obtained. The angle of rotation of the distillate thus obtained is equal to or only slightly greater than that of the original Oil, and the refractive index of this portion, at 20° C. (68° F.), is not less than 0.0008 nor more than 0.0015 lower than that of the original Oil at 20° C. (68° F.)." *U. S.*

A waxy non-volatile substance is present in oil of orange, which interferes with the transparency of solution made with 90 per cent. alcohol. This oil is one of the most difficult to preserve. A method for its preservation, which we have used for years, is to shake the oil briskly with one-eighth of its volume of distilled water, and allow it to separate, then remove the essential oil, filter rapidly if necessary, and mix the filtered oil with 95 per cent. alcohol in the proportion of one volume of the oil to seven volumes of alcohol.

It may be preserved indefinitely by adding 10 per cent. of its volume of olive oil.

The oil of orange is used chiefly as a flavoring agent but Zickgraf (*M. M. W.*, 1910, lvii, p. 1070) speaks very highly of its effect in *chronic bronchitis* for the same class of cases in which oil of turpentine is used. It has the advantages over the latter of being much more pleasant to take and non-irritant to the kidneys.

Dose, three to five minims (0.2–0.3 mil).

S.;* Elixir Vanillini Compositum (from Compound Spirit), *N. F.;* Spiritus Cardamomi Compositus, *N. F.;* Spiritus Myreiæ Compositus, *N. F.;* Spiritus Vanillini Compositus, *N. F.*

OLEUM CADINUM. U. S., Br.

OIL OF CADE Ol. Cadin. [Cade Oil Oil of Juniper Tar, Oleum Juniperi Empyreumaticum]

(ō'lę-ŭm cą-dī'nŭm)

"An empyreumatic oil obtained by the dry distillation of the wood of *Juniperus Oxycedrus* Linné (Fam. *Pinaceæ*)." *U. S.* "Oil of Cade is an empyreumatic oily liquid obtained by the destructive distillation of the woody portions of Juniperus Oxycedrus, *Linn.*" *Br.*

Juniper Tar Oil; Huile de Cade, *Fr.;* Kadeöl, Kadiöl, *G.*

The *Juniperus Oxycedrus,* Linné, *prickly*

cedar, or *large brown-fruited juniper,* is a common tree in the waste places and stony hill-sides of the Mediterranean districts of Northern Africa, Spain, Portugal, and France, reaching up in its distribution as high as 3000 feet in the Apennines. It commonly attains a height of from ten to twelve feet, sometimes much more, with long spreading branches and slender drooping branchlets, covered with light-green scattered and spreading leaves of medium size, lanceolate or awl-shaped, sharply pointed, having two furrows on their upper edge. The fruits are numerous, large (half an inch in diameter), globular, shining, reddish or chestnut-brown, and marked on the apex with two white scars indicating the separation of the carpels.

From the heart-wood of this tree the oil of cade is prepared by a process of distillation in ovens *per descensum,* similar to that practised in the making of ordinary tar. It is a brownish or dark brown liquid, much more mobile and less thick than tar, having a tar-like but distinct odor, and a smoky, acrid, bitterish, disagreeable taste. In mass it is dark and opaque, but in very thin layers clear; the oil contains phenols and a sesquiterpene termed *cadinene,* $C_{15}H_{24}$, the latter boiling at from 274° to 275° C. (525.2°–527° F.), and having a sp. gr. of 0.918 at 20° C. (68° F.).

"Oil of Cade is a dark brown, clear, thick liquid, having a tarry, empyreumatic odor and a warm, faintly aromatic, and bitter taste. It is almost insoluble in water, but imparts to it an acid reaction. It is only partially soluble in alcohol or petroleum benzin, completely soluble in 3 volumes of ether, soluble in amyl alcohol, chloroform, glacial acetic acid, or oil of turpentine. Specific gravity: 0.980 to 1.055 at 25° C. (77° F.). Shake 1 part of Oil of Cade with 20 parts of warm distilled water and filter; separate portions of this filtrate give a red coloration with a few drops of ferric chloride solution (1 in 1000) and reduce silver ammonium nitrate T.S. in the cold and alkaline cupric tartrate T.S. on heating. Agitate 1 mil of Oil of Cade with 15 mils of purified petroleum benzin, filter the benzin solution, add an equal volume of copper acetate solution (1 in 100), shake the mixture and then allow it to separate. On adding an equal volume of ether to the separated benzin solution, it produces no intensely green coloration and does not become colored more than light yellow to brown (*rosin and rosin oil*)." *U. S.*

"A dark reddish-brown or nearly black, oily liquid. Empyreumatic odor; taste aromatic, bitter and acrid. Specific gravity about 0.990. Soluble in *ether,* and in *chloroform;* partially soluble in cold, almost wholly soluble in hot *alcohol* (90 per cent.); very slightly soluble in *water,* the filtered aqueous solution being almost colorless and acid to *litmus.* Yields no reaction for pine tar when tested as follows: Shake 1 millilitre of the Oil vigorously with 15 millilitres of *petroleum spirit,* and filter; to 10 millilitres of the filtrate add 10 millilitres of *solution of copper acetate,* shake vigorously, and set aside until separation into two layers is complete; 5 millilitres of the upper layer, when mixed with 10 millilitres of *ether,* become pale brownish-yellow, but not green (absence of pine tar)." *Br.*

Yaucher recommends acetone for disguising the odor of oil of cade, and proposes an *oil of cade collodion* in which acetone is used to dissolve the pyroxylin instead of the usual solvents. (*C. D.,* 1897, 16.)

Uses.—Oil of cade has been used locally, by the peasantry, in the treatment of the cutaneous diseases of domestic animals almost from time immemorial. More recently it has been largely employed in the treatment of *chronic eczema, psoriasis,* and other skin diseases of man, and has also been found to be an efficient parasiticide in *psora* and *favus.* It is applied, sometimes of full strength, sometimes diluted with a bland oil, well rubbed into the affected parts with the fingers, or with a cloth, and is also made into ointments, and especially into soaps. A glycerite is also prepared. It is very rarely, if ever, used internally, but probably resembles oil of tar in its physiological action.

Dose, one to three minims (0.06–0.2 mil).

Off. Prep.—Linimentum Saponis Mollis Compositum, *N. F.;* Petroxolinum Cadini, *N. F.;* Petroxolinum Sulphuratum Compositum, *N. F.;* Unguentum Sulphuris Compositum, *N. F.*

OLEUM CAJUPUTI. U. S., Br.

OIL OF CAJUPUT Ol. Cajup. [Cajuput Oil Oil of Cajeput]

(ō'lę-ŭm căj-ų-pū'tī)

"A volatile oil distilled from the fresh leaves and twigs of several varieties of *Melaleuca Leucadendron* Linné, especially the var. *Cajeputi* Roxburgh and the var. *minor* Smith (Fam. *Myrtaceæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place." *U. S.* "Oil of Cajuput is the oil distilled from the leaves of Melaleuca Leucadendron, *Linn.,* and other species of Melaleuca." *Br.*

Oleum Cajeputi; Essence de Cajeput, Huile volatile de Cajeput, *Fr.;* Cajeputöl, *G.;* Essenza di Cajeput, *It.;* Esencia de Cayeput, *Sp.;* Kayuputieh, *Mal.*

It was long supposed that the *oil of cajuput* was derived only from *Melaleuca Leucadendron,* but it is now well established that it is derived chiefly from one or more varieties of this species. They are trees indigenous to upper India, the Islands of the Indian Ocean, Northern Australia, Queensland and New South Wales. (See *The Volatile Oils,* Gildemeister and Hoffmann.) It is possible, however, that the oil may also be obtained from different species of *Melaleuca,* as Stickel of Jena, succeeded in procuring from the leaves of *M. hypericifolia,* cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajuput oil of commerce, except by a pale-green color. (*Ann. Pharm.,* xix, 224.) *M. viridifolia* and *M. latifolia,* large trees growing abundantly in the Island of New Caledonia, yield a volatile oil very analogous to the oil of cajuput.

Melaleuca Leucadendron Linné (*M. Cajuputi*

Rumphius) grows with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish ash color, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes. The leaves have short footstalks, are alternate, lanceolate, when young sericeous, when full-grown smooth, deep green, three- and five-nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch broad, and when bruised exhale a strong aromatic odor. The flowers are small, white, inodorous, sessile, and disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bracts. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves and the extensive use made of it in India render it somewhat costly.

Properties.—Cajuput oil is very fluid, transparent, of a fine green color, a lively and penetrating odor analogous to that of camphor and cardamom, and a warm, pungent taste. Upon rectification the green color disappears. It is very volatile and inflammable, burning without any residue. The sp. gr. varies from 0.914 to 0.9274. Its chief constituent has the formula $C_{10}H_{18}O$, and by repeated distillation over phosphoric oxide the hydrocarbon, $C_{10}H_{16}$, called *cajuputene,* can be obtained. The oil is, therefore, said to contain *cajuputene hydrate,* or *cajuputol.* The identity of cajuputol with *cineol* and *eucalyptol* from *Eucalyptus Globulus* in both chemical and physical properties was established by Wallach in 1884 and by C. Jahns (*A. J. P.,* 1885, 237.) It boils at 175° C. (347° F.). A second constituent of the formula $C_{10}H_{18}O$ is the solid *terpineol,* which is present both in the free state and as acetic ester. A small amount of l-pinene and traces of aldehydes have been found, including valeraldehyde and benzaldehyde. (*Schimmel & Co.'s Report,* April, 1897.) Oil of cajuput is "a colorless or yellowish liquid having a peculiar, agreeable, distinctly camphoraceous odor, and an aromatic, slightly bitter taste. It is soluble in 1 volume of 80 per cent. alcohol. Specific gravity: 0.912 to 0.925 at 25° C. (77° F.). Its optical rotation does not exceed –4° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). It does not respond to the Test for heavy metals in volatile oils (see Part III, Test No. 3)." *U. S.*

"Green or bluish-green. Agreeable, camphoraceous odor; taste aromatic, bitter and camphoraceous. Specific gravity 0.919 to 0.930; *optical rotation* not more than –4°; *refractive index* at 25° C. (77° F.) 1.460 to 1.467. When 10 millilitres of the Oil are mixed with 4 to 5 millilitres of *syrupy phosphoric acid* in a vessel surrounded by a freezing mixture, and then pressed strongly in a piece of fine calico between folds of blotting-paper, the pressed cake, decomposed by warm *water* in a graduated vessel, yields an oily layer, which, on cooling to 15.5° C. (60° F.), measures not less than 4.5 millilitres (presence of not less than 45 per cent. of cineol)." *Br.*

The U. S. requires the oil to be colorless or yellow, but according to the Br. it has a greenish tint. When it is distilled, a light, colorless liquid first comes over, and afterwards a green and denser one. The green color has been ascribed to a salt of copper derived from the vessels in which the distillation is performed, and Guibourt obtained two grains and a half of copper oxide from a pound of the commercial oil. But neither Brande nor Goertner could detect copper in specimens examined by them, and Lesson, who witnessed the process for preparing the oil at Bouro, attributes its color to chlorophyll or some analogous principle, and states that it is rendered colorless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a *Melaleuca* cultivated at Paris. A fair inference is that the oil of cajuput is naturally green, but that as found in commerce it sometimes contains copper, either accidentally present or added with a view of imitating or maintaining the fine color of the oil. The proportion of copper, however, is not so great as to forbid the internal use of the oil, and the metal may be separated by distillation with water, or by agitation with a solution of potassium ferrocyanide. This statement as to the frequent occurrence of copper in the cajuput oil of commerce, though at the same time its presence is not desirable, has been confirmed by experiments by Edward Histed, who found copper in all of six specimens of the commercial oil, obtained from different sources. When redistilled, the oil became perfectly colorless, but after a few days' exposure to copper filings reassumed its green color. (*P. J.,* 1872, p. 804.)

Oil of cajuput is said to be often adulterated with oils derived from other than the official species of *Melaleuca.* Oil of rosemary, and oil of turpentine, impregnated with camphor and colored with the resin of milfoil, are also said to be employed as adulterants. The best test, according to Zeller, is iodine, which, after a moderately energetic reaction, with little increase of temperature and but a slight development of orange vapors, occasions immediate inspissation into a loose coagulum, which soon becomes dry, greenish-brown, brittle mass.

Uses.—This oil is highly stimulant, producing when swallowed, a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is much esteemed by the Malays and other people of the East, who consider it a panacea. Formerly the oil of cajuput was used internally in *chronic rheumatism, low fevers,* and various other complaints, but is rarely employed at present for its alterative effects. It is useful internally as a stimulating expectorant in *chronic laryngitis* and *bronchitis,* as a urinary antiseptic in *cystitis,* and as an anthelmintic

especially against the *round worm.* Its most frequent uses, however, are externally in the treatment of various skin diseases. For this latter group of affections it is used for its antiparasitic effect in such diseases as *scabies, tinea versicolor,* etc., and for its stimulating action in *acne rosaceæ, psoriasis,* and other chronic conditions. It is also used externally as a counter-irritant in *chronic rheumatism* and other painful conditions. Like many other essential oils it *relieves toothache* if introduced into the hollow carious tooth.

Dose, from three to ten minims (0.2–0.6 mil).

Off. Prep.—Linimentum Crotonis, *Br.;* Spiritus Cajuputi, *Br.;* Linimentum Tiglii, *N. F.*

OLEUM CARI. U. S. (Br.)

OIL OF CARAWAY Ol. Cari [Caraway Oil]

(ō'lę-ŭm cā'rī)

"A volatile oil distilled from the fruit of *Carum Carvi* Linné (Fam. *Umbelliferæ*), and yielding not less than 50 per cent., by volume, of carvone [$C_{10}H_{14}O = 150.11$]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Caraway is the oil distilled from Caraway Fruit, and rectified." *Br.*

Oleum Carui, *Br.;* Huile volatile de Carvi, *Fr. Cod.;* Essence de Carvi, *Fr.;* Oleum Carvi, *P. G.;* Kümmelöl, Carvon, *G.*

This oil is prepared to a considerable extent by our distillers. The fresh fruit as cultivated in Holland yields nearly 6 per cent. of oil, while the German fruit yields about 4 per cent. The oil of caraway is somewhat viscid, of a pale yellow color, becoming brownish by age, with the odor of the fruit, and an aromatic acrid taste. Its sp. gr. is differently given at 0.946 (Baumé), 0.931 (Brande), 0.916 (Buignet), and 0.900 to 0.910 at 25° C. (77° F.). (*U. S. P.*) It is dextrogyrate in its relation to polarized light. (Buignet, *J. P. C.,* Oct., 1861, p. 261.) It consists of two liquid oils, of different boiling points, and separable by distillation:—one a hydrocarbon called *carvene,* $C_{10}H_{16}$, of the specific gravity 0.849 and boiling point 176° C. (349° F.), now recognized as identical with d-limonene, the other, the valuable constituent, *d-carvone,* $C_{10}H_{14}O$, of the sp. gr. 0.9638 and boiling point 224° C. (435° F.). This latter constituent is often extracted from the oil and prepared in a pure state by taking advantage of the formation of a crystalline compound of carvone and hydrogen sulphide, which can then be decomposed by treatment with alcoholic potassium hydroxide.

Sulphides are found in the aqueous distillate which comes over with the oil, as are also several constituents which are ordinarily considered only to accompany destructive distillation products as methyl alcohol, acetaldehyde, etc.

Properties.—It is officially described as "a colorless or pale yellow liquid, having the characteristic odor and taste of caraway. It is soluble in 8 volumes of 80 per cent. alcohol. Specific gravity: 0.900 to 0.910 at 25° C. (77° F.). Its optical rotation varies between +70° and +80° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)." *U. S.*

"Colorless or pale yellow. Odor and taste those of Caraway Fruit. Specific gravity 0.910 to 0.920; *optical rotation* +75° to +82°; *refractive index* at 25° C. (77° F.) 1.485 to 1.497. Soluble in 1 part of *alcohol* (90 per cent.), and in 10 parts of a mixture of equal volumes of *alcohol* (90 per cent.) and *alcohol* (70 per cent.). When fractionally distilled from a distillation flask at the rate of one drop per second, not less than 50 per cent. distils at a temperature above 200° C. (392° F.)." *Br.*

"**Assay.**—Introduce 10 mils of the Oil into a 200 mil flask with a long graduated neck (cassia flask) by means of a pipette, add 50 mils of a saturated solution of sodium sulphite, which has been carefully rendered neutral to phenolphthalein T.S. by means of acetic acid, heat the mixture in a bath containing boiling water and shake the flask repeatedly, neutralizing the mixture from time to time by the addition of a few drops of diluted acetic acid. When no coloration appears, upon the addition of a few more drops of phenolphthalein T.S. and heating for fifteen minutes, cool, and, when the liquids have separated completely, add sufficient of the sodium sulphite solution to raise the lower limit of the oily layer within the graduated portion of the neck and note the volume of the residual liquid. This measures not more than 5 mils, indicating the presence of not less than 50 per cent., by volume, of carvone." *U. S.*

For additional tests, see *Schim. Rep.,* 1893, 10; also *Bull. Pharm.,* 1894, 257. Kremers and Schreiner (*Ph. Rev.,* xiv, 76) recommend a method of determining the value of oil of caraway based on the conversion of carvone into its oxime, and the separation of the carvoxime from the terpenes by steam distillation; it is as follows: "To a solution of 10 Gm. of oil, dissolved in 25 mils of alcohol, 5 Gm. of hydroxylamine hydrochloride and 6.5 Gm. of sodium bicarbonate are added. This mixture is boiled on a water bath for half an hour in a flask connected with a reflux condenser, 25 mils of water are then added, and the alcohol is distilled off on the water bath. Steam is then passed through the liquid until traces of carvoxime come over. The last portions of the distillate are collected separately in test tubes, and when traces of crystals of carvoxime appear on the surface, the operation is interrupted. The tube of the condenser is washed with a little hot water, and this, as well as the last collected distillate, containing some carvoxime, is returned to the flask. The contents of the flask are allowed to cool, and after the carvoxime has completely solidified, it is removed from the sides of the flask by means of a loop of stiff wire, thrown upon a force filter, washed, and dried by suction. The air-dried carvoxime is transferred to a tared glass dish and heated for 1 hour on a water bath, and when cool, weighed. To the weight thus obtained 0.100 Gm. is added, as this is about the quantity lost during heating. From the

weight of the carvoxime that of the carvone may be readily calculated, 164.67 parts of the former corresponding to 149.66 parts of the latter, or the weight of carvoxime obtained, expressed in Gm., when multiplied by 0.9088, gives he weight of the equivalent amount of carvone."

When oil of caraway is distilled over glacial phosphoric acid or powdered sodium hydroxide, the distilled liquor being poured back into the retort until it ceases to have the odor of caraway, it yields carvacrol. (See Part II.)

Oil of caraway is used to impart flavor to medicines, and to correct their nauseating and griping effects.

Gmeiner (*B. Thier. W.*, 1909, p. 695) recommends the use of oil of caraway in the treatment of *scabies*. He employs a solution in castor oil containing five parts of alcohol and oil of caraway in seventy-five parts of castor oil.

Dose, from one to five minims (0.06–0.3 mil).

Off. Prep.—Pilula Aloes, *Br.;* Spiritus Juniperi Compositus, *U. S.;* Elixir Cardamomi Compositum (from Compound Spirit), *N. F.;* Mistura Carminativa, *N. F.;* Spiritus Cardamomi Compositus, *N. F.*

OLEUM CARYOPHYLLI. U. S., Br.

OIL OF CLOVE Ol. Caryoph. [Clove Oil Oil of Cloves]

(ō'lę-ŭm căr-ŷ-o-phŷl'lī)

"A volatile oil distilled from the flower-buds of *Eugenia Aromatica* (Linné) O. Kuntze [*Jambosa Caryophyllus* (Sprengel) Niedenzu] (Fam. *Myrtaceæ*), and yielding not less than 82 per cent., by volume, of eugenol [$C_{10}H_{12}O_2$ = 164.10]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Cloves is the oil distilled from Cloves." *Br.*

Huile volatile de Girofle, *Fr. Cod.;* Oleum Caryophyllorum, *P. G.;* Nelkenöl, Eugenol, *G.;* Essenza di garofani, *It.;* Esencia de clavo, *Sp.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition, and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Scharling has found advantage from the application of superheated steam to the distillation of this oil. (*P. J.*, xi, 469.) It is essential also to use the same water over and over again, in order to avoid loss by the solution of the oil in the water. The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies, but since the introduction of the Cayenne cloves into our markets the reduced price and superior freshness of the drug have rendered the distillation of oil of clove profitable in this country, and the best now sold is of domestic extraction. The exportation of clove from Zanzibar in 1909 was over 20,000,000 pounds. We have been informed that from seven to nine pounds of clove yield to our distillers about one pound of the oil.

Properties.—Oil of cloves, when recently distilled, is very fluid, clear, and colorless (but becomes yellowish by exposure, and ultimately reddish-brown). It has the odor of cloves, a hot, acrid, aromatic taste, and a slightly acid reaction. Its sp. gr. is variously stated at from 1.034 to 1.061, the latter being given by Bonastre as the sp. gr. of the rectified oil.

"Oil of Clove is a colorless or pale yellow liquid, becoming darker and thicker by age and exposure to the air, having the characteristic odor and taste of clove. It is soluble in 2 volumes of 70 per cent. alcohol. Specific gravity: 1.038 to 1.060 at 25° C. (77° F.). Its optical rotation does not exceed –1° 10′ in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). Shake 1 mil of the Oil with 20 mils of hot distilled water; the water shows not more than a scarcely perceptible acid reaction with litmus. After cooling, pass the aqueous layer through a wetted filter; the clear filtrate, with a drop of ferric chloride T.S., yields only a transient, grayish-green color, but not a blue or violet color (*phenol*).

"**Assay.**—Introduce 10 mils of the Oil into a flask with a long graduated neck (cassia flask), add 50 mils of potassium hydroxide T.S., shake the mixture for five minutes and then heat it on a water bath during ten minutes, cool and when the liquids have separated completely, add sufficient potassium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck and note the volume of the residual liquid. This measures not more than 1.8 mils, indicating the presence of not less than 82 per cent., by volume, of eugenol." *U. S.*

"Colorless or pale yellow when fresh, darkening with age and on exposure to air. Odor and taste those of Cloves. Specific gravity 1.047 to 1.065; *refractive index* at 25° C. (77° F.) 1.528 to 1.540. Soluble in 3 parts of *alcohol* (70 per cent.), the solution yielding a blue color with *T. Sol. of ferric chloride.* When 10 millilitres of the Oil are well shaken with 100 millilitres of *solution of sodium hydroxide*, heated on a water-bath in a flask with a narrow graduated neck, and then allowed to stand, the uncombined oil, cooled to 15.5° C. (60° F.), measures not more than 1.5 millilitres (presence of not less than 85 per cent. of eugenol)." *Br.*

Oil of clove is one of the least volatile of the essential oils and requires for congelation a temperature from –17.8° to –20° C. (0° to –4° F.). It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its color to a deep red, and converts it by the aid of heat into oxalic acid. The same change to red is produced by nitric acid on morphine, but in this case the red is followed by yellow, which does not happen with the oil of clove. Besides, if to a solution of morphine with nitric acid a solution of chlorinated lime be added, and the mixture be exposed for some hours to the light, the solution of morphine will retain a straw color, while if oil of clove be treated in the same manner the color disappears. (Haselden, *B. F. M. R.*, July, 1867, 265.) It is frequent adulterated with fixed oils, and sometimes with oil of pimenta and with copaiba.

When pure, it sinks in distilled water. According to E. Scherer, these adulterations may sometimes be detected by attention to the specific gravity and the boiling point, pure oil of clove varying in specific gravity from 1.03 to 1.06, and boiling at from 240° C. (464° F.) to 255° C. (491° F.). According to Zeller, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassium hydroxide, losing at the same time its peculiar odor, affords a sufficient criterion of its purity. This, however, while included among the official tests, is not sufficient, the percentage of eugenol as determined by the official assay being now a requirement.

Oil of clove contains small amounts of vanillin, methyl alcohol and furfurol, but is mainly composed of an unsaturated phenol termed eugenol which is now an official product (see *Eugenol*) and its acetic derivative and a sesquiterpene *caryophyllene*. Eugenol acetyl salicylate has also been reported. The U. S. Pharm. IX introduced an assay process for the eugenol content.

Eugenol, $C_{10}H_{12}O_2$ (see p. 432), has been shown to be the methyl ether of allyl-dioxybenzene, $C_6H_3\begin{cases}C_3H_5\\OCH_3\\OH\end{cases}$. One of its most important reactions is its conversion into *vanillin*. For this purpose it is boiled with acetic anhydride, whereby *aceteugenol* is formed, which, oxidized in weak acid solution by potassium permanganate, yields *acetvanillic acid*, and this with weak potassium hydroxide solution is changed into vanillin, which is then extracted by acidifying and shaking up with ether. (See also *Ph. Era*, 1887, 444.) For the estimation of eugenol in the form of its crystalline benzoyl compound, see *A. J. P.*, 1892, 26 and 508; also *Schim. Rep.*, April, 1892, 28. The characteristic aromatic odor of oil of clove is due to *methylamylketone*, $CH_3.CO.C_5H_{11}$, which has been isolated by the chemists of Schimmel & Co., and found to be present only in minute quantity. (*Ph. Rev.*, 1897, 115.)

Uses.—By virtue of its local irritant effect oil of clove stimulates peristalsis and is frequently a useful remedy in the treatment of *flatulent colic*. It is also an active local anesthetic and is a favorite remedy for *toothache;* for this purpose a small pledget of cotton is saturated with oil and inserted into the carious cavity. It is a powerful germicide, far exceeding phenol in activity, but is not frequently used for this purpose. Eugenol has been used internally in doses of forty-five grains (3 Gm.) *per diem* as an antiseptic antipyretic. Little, however, is known of its physiological action. According to Leubuscher (*W. M. Bl.*, 1889) it is a feeble local anesthetic. Landis (*T. G.*, 1909, xxxiii, 386) has used oil of clove as a stimulant expectorant in *tuberculosis* and *bronchiectasis* with good results.

Dose, from two to six minims (0.12–0.4 mil).

OLEUM CASSIÆ. U. S. (Br.)

OIL OF CINNAMON Ol. Cass. [Oleum Cinnamomi U. S. VIII Cassia Oil]

(ō'lę-ŭm căs'si-æ)

"A volatile oil distilled from *Cinnamomum Cassia* (Nees) Blume (Fam. *Lauraceæ*), rectified by steam distillation and yielding not less than 80 per cent., by volume, of cinnamic aldehyde [C_9H_8O = 132.06]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Cinnamon is the oil distilled from Cinnamon Bark." *Br.*

Oleum Cinnamomi, *Br.;* Oleum Cinnamomi Cassiæ; Oil of Chinese Cinnamon, Essence de Cannelle de Chine, Huile volatile de Cannelle, *Fr.;* Oleum Cinnamomi, *P. G.;* Zimmtöl, Zimmtkassienöl, *G.;* Essenza di Cannella, *It.*

There are two oils of cinnamon in commerce, one procured from the Ceylon cinnamon, the other from the Chinese cinnamon, and often distinguished by the name of *oil of cassia*. There is no essential difference in the two oils, and that of the Chinese cinnamon, as much the cheaper and more abundant of the two, will probably continue to be generally employed, notwithstanding that the Ceylon product has the finer flavor. The U. S. P. IX and the German Pharmacopœia recognize as oil of cinnamon only that obtained from cassia. The British Pharmacopœia and French Codex make Oil of Ceylon Cinnamon official.

Preparation.—Oil of cinnamon of Ceylon is distilled from inferior kinds of cinnamon, of insufficient value to pay the export duty. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea water, and then submitted to distillation. A light and a heavy oil come over with the water, the former of which separates in a few hours and floats upon the surface, the latter falls to the bottom of the receiver, and continues to be deposited for ten or twelve days. In future distillations, the saturated cinnamon water is employed with sea water to macerate the cinnamon. Eighty pounds of the freshly prepared bark yield about 2.5 ounces of the lighter oil, and 5.5 of the heavier. From the same quantity kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce. The oil is also distilled in Ceylon from the leaves, but the product is said to be too small to yield a fair profit. (*C. D.*, 1888.) The exportation of cinnamon chips from Ceylon has assumed large proportions, amounting in 1904 to 2,135,220 pounds. (*Schim. Rep.*, May, 1905.)

Properties.—Oil of Ceylon cinnamon is of a light-yellow color, becoming deeper by age, and ultimately red. Pereira stated that the London druggists redistilled the red oil, and thus obtained two pale-yellow oils, one lighter and the

other heavier than water, with a loss of about 10 per cent. in the process. The oil has the flavor of cinnamon, and when undiluted is excessively hot and pungent. It is said sometimes to have a peppery taste, ascribable to an admixture of the leaves with the bark in the preparation of the oil. *Oil of Ceylon cinnamon* has "a slightly acid reaction. Sp. gr. about 1.040. It is readily soluble in alcohol. When cooled to –10° C. (14° F.), it remains clear, but at a lower temperature a solid portion separates from it." *U. S.* 1880. To ascertain whether, in the distillation of oil of cinnamon from the bark, some of the oil is oxidized to cinnamic aldehyde in part and thus the yield lowered, H. A. Phillips (*Tr. Br. Ph. Conf.*, 1914, 371) made a thorough investigation of the subject and concludes that under the ordinary conditions of steam distillation, cinnamic aldehyde is not appreciably oxidized. The British Pharmacopœia 1914 recognizes oil of Ceylon cinnamon only, and gives the following description and tests: "Yellow when freshly distilled, gradually becoming reddish. Odor and taste those of Cinnamon Bark. Specific gravity 1.000 to 1.030; *optical rotation* –0.5° to –1°; *refractive index* at 25° C. (77° F.) 1.565 to 1.580. Soluble in from 3 to 4 parts of *alcohol* (70 per cent.). 1 drop dissolved in 5 millilitres of *alcohol* (90 per cent.) assumes a pale green, but not a blue or brown coloration, on the addition of 1 drop of *T. Sol. of ferric chloride* (absence of cinnamon leaf oil and cassia oil). Contains from 55 to 65 per cent. of cinnamic aldehyde as determined by the following test: To 10 millilitres of the Oil add 70 millilitres of an aqueous solution (1 in 5) of *sodium sulphite* and sufficient *solution of phenolphthalein* to give a well marked pink coloration. Heat the mixture on a water-bath, shake well, and neutralise with *acetic acid* diluted with twice its volume of *water;* repeat the heating and neutralisation until no further pink coloration is developed, the time occupied being from thirty to forty-five minutes. The oily layer which separates on standing, cooled to 15.5° C. (60° F.), measures not more than 4.5 or less than 3.5 millilitres (presence of 55 to 65 per cent. of cinnamic aldehyde)." *Br.*

Chinese oil of cinnamon is imported from Canton and Singapore. It is pale yellow, becoming red with age. Its flavor is similar to that of the Ceylon oil, though inferior, and it commands a much lower price. It is officially described as follows: "Oil of Cinnamon (Cassia) is a yellowish or brownish liquid, becoming darker and thicker by age and exposure to the air and having the characteristic odor and taste of cinnamon. Specific gravity: 1.045 to 1.063 at 25° C. (77° F.). The optical rotation varies from +1° to –1° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). It does not respond to the Test for heavy metals in volatile oils (see Part III, Test No. 3). Shake 2 mils of the Oil in a test tube with from 5 to 10 mils of purified petroleum benzin, and decant the latter; this liquid is colorless and does not assume a green color upon shaking it with an equal volume of (1 in 1000) copper acetate solution (*rosin*).

"**Assay.**—Proceed as directed under *Oleum Cari,* using 10 mils of Oil of Cinnamon. It shows not less than 80 per cent., by volume, of cinnamic aldehyde." *U. S.*

The researches of Schimmel & Co. seem to show that the Chinese cassia oil of commerce is distilled from the leaves, leaf-stalks, and young twigs of the cassia plant—probably with broken bark and various refuse products from the tree; also that much of the oil is adulterated with rosin and petroleum. (See official tests above.) The value of cassia oil depends upon the percentage of cinnamic aldehyde which it contains. Cinnamyl acetate and cinnamic acid are also present as well as small amounts of phenylpropyl acetate and orthocumaric aldehyde. In the oil of Ceylon cinnamon, cinnamic aldehyde is the chief constituent, but eugenol is present to the extent of over 5 per cent., and phellandrene has also been reported. Cinnamon leaf oil contains much eugenol and very little cinnamic aldehyde, safrol and benzaldehyde being present as minor constituents. (See *Cinnaldehydum* and the official assay of oil of cinnamon for the percentage of cinnamic aldehyde.) In a series of analyses made by Schimmel & Co. of oils having a specific gravity of 1.064 to 1.065, the proportion of aldehyde varied from 73.5 to 88 per cent. In the distillation by Schimmel & Co. the various portions of the cassia plant obtained from China yielded the following results. 1. Cassia bark, *Cassia lignea* of commerce: yield of essential oil 1.5 per cent.; aldehyde in oil 92 per cent.; sp. gr. 1.035. 2. Cassia buds, *Flores Cassiæ* of commerce: yield of essential oil 1.550 per cent.; aldehyde in oil 80.4 per cent.; sp. gr. 1.026. 3. Cassia budsticks: yield of essential oil 1.64 per cent.; aldehyde in oil 92 per cent.; sp. gr. 1.046. 4. Cassia leaves, leaf-stalks, and young twigs mixed: yield of essential oil 0.77 per cent.; aldehyde in oil 93 per cent.; sp. gr. 1.055. Zeller states that oil of cassia is heavier, less liquid, and sooner rendered turbid by cold, and that in the Ceylon oil, iodine dissolves rapidly, with a considerable increase of heat, and the production of a tough residue, like an extract, while in oil of cassia the reaction is slow, quiet, and with little heat, and the residue is soft or liquid.

The *cinnamon leaf oil,* as formerly imported into Great Britain, was of two kinds, one containing a considerable quantity of a fatty fixed oil, perhaps cinnamon-suet from the fruit, the other a pure volatile oil. The oil was said to be obtained by distilling the leaves after maceration in sea water. It resembled the oil of clove and pimento in sensible properties, having a brownish color, a penetrating, fragrant odor, and a very pungent taste. According to Stenhouse, it was of the sp. gr. 1.053, had an acid reaction, and consisted of eugenol, a neutral substance with the formula $C_{10}H_{16}$, and a minute proportion of benzoic acid. (*P. J.*, xiv, 319.) Schimmel & Co. found it to have a sp. gr. 1.056

to 1.060, and contained 87 per cent. of eugenol, and about 0.1 per cent. of cinnamic aldehyde.

When exposed to the air, the oil absorbs oxygen, and is slowly converted into cinnamic acid, two distinct resins, and water. Of the two resins, one is soluble both in hot and in cold alcohol; the other readily in the former, but sparingly in the latter. *Cinnamic acid,* $C_9H_8O_2$, is colorless, crystalline, sourish, volatilizable, slightly soluble in water, readily dissolved by alcohol, and convertible by nitric acid with heat into benzoic acid. It is sometimes seen in crystals in oil of cinnamon which has been long kept. Like benzoic acid, it is said when swallowed to cause the elimination of hippuric acid by the urine. (*J. P. C.,* 3e sér., iii, 64.) It may be obtained by distilling the balsam of Tolu. Oil of cinnamon is almost wholly converted by nitric acid, slowly added, into a crystalline mass, producing a compound of the oil and the acid. These several facts are explained when it is found that oil of cinnamon contains from 75 to 90 per cent. of *cinnamic aldehyde,* C_9H_8O (see *Cinnaldehydum,* U. S. P. VIII), which by moderate oxidation yields the corresponding cinnamic acid, $C_9H_8O_2$, but by more energetic oxidation yields benzoic acid, $C_7H_6O_2$. The oil has been produced artificially by Strecker from styrone, a derivative from styrax (see *Styrax*), and more recently from benzaldehyde and acetaldehyde, a mixture of which is saturated with hydrochloric acid gas, when a condensation takes place, as follows:

$$C_6H_5COH + CH_3COH = C_6H_5.CH:CH.CHO + H_2O$$

Ordinary sodium hydroxide will also bring about the reaction between the two aldehydes, and is to be preferred to hydrochloric acid for this purpose.

Oil of cinnamon is said to be frequently adulterated with oil of cloves, which, according to Ulex, cannot be detected by the odor or taste. Thus sophisticated, it is stated, on the same authority, to evolve a very acrid vapor when a drop is heated on a watch glass, to swell up and evolve red vapors if treated with fuming nitric acid, to remain liquid with concentrated potassium hydroxide, and to assume an indigo-blue color when ferrous chloride is added to its alcoholic solution, none of which reactions occur with pure oil.

Uses.—Although a very powerful germicide the oil of cinnamon, because of its irritant properties, is rarely used in medicine as an antibacterial. It has the cordial and carminative properties of cinnamon, without its astringency, and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in *gastrodynia, flatulent colic,* and *gastric debility.* Mitscherlich found six drachms to kill a moderate-sized dog in five hours, and two drachms one in forty hours. Inflammation and corrosion of the gastro-intestinal mucous membrane were observed after death.

Dose, one to three minims (0.06–0.2 mil).

OLEUM CHAULMOOGRÆ. Br.

CHAULMOOGRA OIL

(ō'lę-ŭm ċhâul-moog'rą)

"Chaulmoogra Oil is the fatty oil expressed from the seeds of Taraktogenos Kurzii, *King.*" *Br.*

Oleum Gynocardiæ, Gynocardia oil, Chaulmugra oil.

Under the name of chaulmoogra oil there has long been used in Southeastern portions of Asia a semi-solid fat. This was at one time believed to be derived from the *Gynocardia odorata* and has therefore been erroneously called gynocardia oil, but the investigations of Power (*A. J. P.,* 1915, p. 493) have shown that the oil from the gynocardia seed is very different both in chemical composition and physical properties. The true chaulmoogra oil is derived from the *Taraktogenos Kurzii* King (Fam. *Bixaceæ*). It is possible that some of the commercial oil may also be derived from the species of the allied genus *Hydnocarpus.* The chaulmoogra seeds are from one to one and a quarter inches long, more or less angular or flattened, and yield upon expression, from 25 to 30 per cent., to ether, about 50 per cent. of oil. The commercial oil is obtained by expression, or sometimes by boiling the crushed seeds with water. It is "a brownish-yellow oil or soft fat. Characteristic odor; taste somewhat acrid. Melting point about 22° to 30° C. (71.6°–86° F.). Specific gravity at 45° C. (113° F.) about 0.940; *saponification value* 198 to 213; *iodine value* 96 to 104; *acid value* 21 to 27. Soluble in *ether,* in *chloroform,* and in *carbon disulphide;* partially soluble in cold *alcohol* (90 per cent.); almost entirely soluble in hot *alcohol* (90 per cent.)." *Br.*

The genuine chaulmoogra oil is dextrorotatory, having a specific rotation of about +52°. It consists of the glycerides of cyclic organic acids of which the most important is *chaulmoogric acid,* $C_{18}H_{32}O_2$, melting at 68° C. (154.4° F.), while a homologue, *hydnocarpic acid,* $C_{16}H_{28}O_2$, melts at 60° C. (140° F.). Palmitic acid and a phytosterol are also present.

The so-called chaulmoogra oil, from gynocardia, is optically inactive and contains none of the acids peculiar to the genuine chaulmoogra oil. It consists of glycerides of linolic, palmitic, linolenic, isolinolenic and oleic acids and a phytosterol, as well as a glucoside, *gynocardin,* $C_{13}H_{19}O_9N$, which resembles amygdalin and which

is associated in the seeds with an enzyme, gynocardase.

Uses.—Chaulmoogra oil was originally employed in its native countries both internally and externally in the treatment of *scrofula, skin diseases,* and *rheumatism.* In England it is very widely used as a counter-irritant application in *bruises, sprains,* and similar local inflammations both of man and beast as well as in *open sores* and *wounds.* Its most important use, however, is in the treatment of *leprosy.* There seems to be little doubt that it is the most useful remedy known for this intractable infection, indeed many authorities have claimed that it will often produce complete and permanent cures. For review of the literature see Engel (*Monatsh. f. prakt. Dermat.,* 1909, xlix, p. 290.) It should be used freely both internally and externally. Donato (*Leprosy in the Philippines and Its Treatment,* Manila, 1915) believes that its action is due to the stimulation of leucocytosis. He recommends the following solution for intramuscular injection: Camphorated oil (10 per cent. camphor), chaulmoogra oil (sterilized), of each, 60 mils; resorcinol, 4 Gm.; ether, 2.5 Gm. Of this solution 1 mil (15 minims) is injected intramuscularly every alternate day, gradually increasing the dose up to 8 or 10 mils or until reaction becomes severe.

Unna has proposed, for oral administration, the use of a soap made from the oil as affecting the stomach and intestines less unpleasantly than the oil itself. (See *P. J.,* lxiv, 615.)

Dose, five to ten minims (0.3–0.6 mil) gradually increased to one fluidrachm (3.75 mils).

Off. Prep.—Unguentum Chaulmoogræ, *Br.*

OLEUM CHENOPODII. U. S.

OIL OF CHENOPODIUM Ol. Chenopod. [Oil of American Wormseed]

(ō'lę-ŭm ȩhĕn-ǫ-pō'dĭ-ī)

"A volatile oil distilled from *Chenopodium ambrosioides anthelminticum* Linné (Fam. *Chenopodiaceæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Huile volatile d'Ansérine vermifuge, *Fr. Cod.;* Essence de Chénopode anthelmintique, *Fr.;* Amerikanisches Wurmsamenöl, Chenopodiumöl, *G.*

For description of the plant from which this oil is derived see *Chenopodium,* Part II. The oil is largely distilled in Maryland. It is of a light-yellow color when recently distilled, but becomes deeper yellow and even brownish by age. Its reaction is neutral. It has in a high degree the peculiar odor of the plant. It is officially described in the United States Pharmacopœia as "a colorless or pale yellowish liquid, having a characteristic, disagreeable odor and taste. It is soluble in 8 volumes of 70 per cent. alcohol. Specific gravity: 0.955 to 0.980 at 25° C. (77° F.). Its optical rotation varies between –4° and –10° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)." *U. S.*

When freshly prepared, it has the sp. gr. 0.908, which, according to S. S. Garrigues, is increased by time to 0.960. A portion examined by him, which was of a brownish-yellow color, had the sp. gr. 0.959 at 16.1° C. (61° F.), boiled at 190° C. (374° F.), and was freely soluble in alcohol and ether. He found it to be composed of two distinct oils, separable by distillation; one of these has the formula $C_{10}H_{16}$, and is probably limonene; the other is heavier, and possesses the formula $C_{10}H_{18}O_2$. This constitutes over 50 per cent. of the commercial oil and has been given the name *ascaridol,* which is an unstable organic dioxide, decomposing with explosive violence with inorganic acids. (*A. J. P.,* xxvi, 405.)

Uses.—The oil of chenopodium is used in medicine almost exclusively as an anthelmintic. Although it has been official in the Pharmacopœia for many years, it owes its modern popularity to the investigations of Brunning. (*Z. E. P. T.,* 1905, i, and 1906, iii, p. 564.) This author showed that one part in five thousand paralyzed although it did not kill the round worm of dogs, and that one part in two hundred had a distinct antiseptic action. In mammals, if given in sufficient dose, it depresses the spinal cord and finally kills by arrest of respiration. According to Salant and Livingston (*A. J. Phys.,* 1915, xxxviii) the oil of chenopodium in doses of 0.02 mil per kilo, or more, produces a lowering of the blood pressure through a cardiac action and diminution in the amplitude and rate of respiration. Because of its efficiency, ease of administration, and low toxicity, it is perhaps the most valuable of all the vermifuge remedies. Although originally recommended against the *ascarides* it has been shown to be also of great service against both the *tapeworm* and the *hookworm.* In the comparative studies of Schuffner and Verwoort (*M. M. W.,* 1913, lx, p. 129) it gave better results in uncinariasis than either eucalyptus, betanaphthol, or thymol.

Levy (*J. A. M. A.,* 1914, lxiii, p. 1946) has collected from the literature twelve cases of poisoning by oil of chenopodium of which nine ended fatally. The smallest dose in this series was four drops three times a day for two days, which caused death in a baby one year old. In another case a child of two recovered from a dose of two teaspoonfuls given in the course of one afternoon. The symptoms of poisoning by oil of chenopodium—which may not appear for several hours after taking the oil—are nausea, vomiting, headache followed by drowsiness, ringing in the ears, and sometimes deafness. In the fatal cases there develop coma and convulsions. The usual method of administration is to give from ten to fifteen drops either in sugar or as an emulsion twice a day for two days and followed on the second day by an ounce of castor oil. For children between the ages of six and twelve the dose should be one drop for each year of age.

Dose, five to fifteen minims (0.3–0.9 mil).

OLEUM COPAIBÆ. Br.

OIL OF COPAIBA

(ō'lę-ŭm cọ-pā'i-bæ)

Oil of Copaiva; Oleum Balsami Copaivæ; Essence de Copahu, *Fr.;* Copaivaöl, *G.*

Oil of copaiba was not admitted to the U.S.P. IX. The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. has been obtained. (*A. J. P.,* xxii, 289.) It is prepared largely by the application of steam heat. As it first comes over it is colorless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colorless. It has the odor and taste of copaiba, a neutral reaction, boils at 252° to 256° C. (485.6°–492.8° F.), solidifies, partly crystalline, at –26.1° C. (–15° F.) (Gmelin), is soluble in ether and in an equal weight of absolute alcohol. The oil consists chiefly of *caryophyllene,* a sesquiterpene, $C_{15}H_{24}$. It was officially described as "a colorless or pale yellow liquid, having the characteristic odor of copaiba, and an aromatic, slightly bitter, and pungent taste. Specific gravity: 0.895 to 0.905 at 25° C. (77° F.), increasing with age. It is lævogyrate." *U.S. VIII.*

"Colorless or pale yellow. Odor and taste those of Copaiba. Specific gravity 0.896 to 0.910; *optical rotation* –7° to –35°; *refractive index* at 25° C. (77° F.) 1.494 to 1.500. Distils between 250° and 275° C. (482° and 527° F.). A solution of 1 millilitre of the Oil in 5 millilitres of *glacial acetic acid* does not develop more than a faint violet coloration on the addition of 4 drops of *nitric acid* (absence of gurjun oil). When distilled in a vacuum the first 10 per cent. of the distillate has an *optical rotation* lower than that of the original Oil (absence of oil of African copaiba)." *Br.*

From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Durand, of Philadelphia. It dissolves sulphur and phosphorus.

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious of the volatile oils to the animal system, six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it produces much less irritation than does oil of turpentine. It may be used for the same purposes as copaiba.

Dose, five to fifteen minims (0.3–0.9 mil).

OLEUM CORIANDRI. U. S., Br.

OIL OF CORIANDER Ol. Coriand. [Coriander Oil]

(ō'lę-ŭm cō-ri-ăn'drī)

"A volatile oil distilled from the ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbelliferæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Coriander is the oil distilled from Coriander Fruit." *Br.*

Essence de Coriandre, *Fr.;* Koriander öl, *G.*

This oil may be obtained by distillation with water from the bruised fruit in the manner directed in the U. S. Pharm. 1870, for volatile oils. The average yield of oil from coriander grown in different countries is from 0.2 to 1 per cent. It is pale yellow and colorless, and has the characteristic odor and taste of coriander, and a neutral reaction. Its sp. gr. is from 0.863 to 0.878 at 25° C. (77° F.), *U. S.,* and its boiling point 150° C. (302° F.). It is an oxygenated oil, consisting chiefly of a compound, *coriandrol,* $C_{10}H_{18}O$. According to Semmler (*Ber. d. Chem. Ges.,* 24, 206), coriandrol boils between 194° and 198° C. (381.2° and 388.4° F.), is optically dextrogyrate, and has a sp. gr. of 0.8679 at 20° C. (68° F.). Coriandrol is now known as dextrogyrate *linalool.* Schimmel & Co. (*Schim. Rep.,* April, 1892) have also found in coriander oil about 5 per cent. of dextropinene. The characteristic odorous principle or principles are unknown. It is officially described as "a colorless or pale yellow liquid, having the characteristic odor and taste of coriander. It is soluble in 3 volumes of 70 per cent. alcohol. Specific gravity: 0.863 to 0.875 at 25° C. (77° F.). The optical rotation varies from +8° to +13° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)." *U. S.*

"Colorless or pale yellow. Odor and taste those of Coriander Fruit. Specific gravity 0.870 to 0.885; *optical rotation* +8° to +14°; *refractive index* at 25° C. (77° F.) 1.463 to 1.467. Soluble in 3 parts of *alcohol* (70 per cent.)." *Br.*

Oil of coriander is extensively adulterated with colorless rectified oil of orange, which can be detected by its insolubility in 90 per cent. alcohol, in which pure coriander oil dissolves in every proportion; equal parts of oil of orange and 90 per cent. alcohol make a turbid mixture. (*A. J. P.,* Sept., 1878.) The oil has the medicinal properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste or correct the nauseating or griping properties of other medicines. It has the great advantage of being more stable and retaining its agreeable odor longer than any other oil of its class.

Dose, one to three minims (0.06–0.2 mil).

Off. Prep.—Spiritus Aurantii Compositus, *U. S.;* Elixir Aromaticum (from Spirit), *U. S.*

OLEUM CUBEBÆ. U. S., Br.

OIL OF CUBEB Ol. Cubeb. [Cubeb Oil]

(ō'lę-ŭm cū-bē'bæ)

"A volatile oil distilled from the unripe fruit of *Piper Cubeba* Linné filius (Fam. *Piper-*

aceæ). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Cubebs is the oil distilled from Cubebs." *Br.*

Oleum Cubebarum; Oil of Cubebs; Huile volatile (Essence) de Cubèbe, *Fr.*; Kubebenöl, *G.*

The oil is obtained from cubeb by grinding the berries, and then distilling with water. From ten pounds Schönwald procured eleven ounces of oil, and this result very nearly coincides with the experiments of Christison, who obtained 7 per cent.; but by better methods of distillation 10 to 18 per cent. have been obtained. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age, but when carefully redistilled it is colorless. It has the odor of cubeb, a warm, aromatic, camphoraceous taste, and a neutral reaction, is of a consistence approaching that of almond oil, is lighter than water, having the sp. gr. 0.920 (0.910 to 0.930, *Br.*), and when exposed to the air is said to thicken without losing its odor. It is soluble in an equal weight of alcohol. It is described in the U. S. P. IX as follows: "Oil of Cubeb is a colorless or a pale green to yellowish-green liquid, having the characteristic odor and taste of cubeb. Specific gravity: 0.905 to 0.925 at 25° C. (77° F.). Its optical rotation varies from –20° to –40° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). Its alcoholic solution is neutral to litmus." *U. S.*

"Colorless, pale green, or greenish-yellow. Odor and taste those of Cubebs. Specific gravity 0.910 to 0.930; *optical rotation* –25° to –40°; *refractive index* at 25° C. (77° F.) 1.486 to 1.500. Not less than 60 per cent. distils between 250° and 280° C. (482°–536° F.)." *Br.*

The oil consists chiefly of sesquiterpenes which distil over between 250° and 280° C. (482° and 536° F.), one of which is *cadinene*, $C_{15}H_{24}$, with some dipentene, and probably pinene or camphene. Upon standing, it sometimes deposits rhomboidal prismatic crystals of a stearopten. The camphor of cubeb has the formula $C_{15}H_{26}O$, is fusible at from 66° to 68° C. (150.8°–154.4° F.), and volatilizes without change at from 148° to 150° C. (298.4°–302° F.). According to Schmidt, it does not pre-exist in the cubeb, but is formed by the prolonged action of the air and therefore does not occur in oil distilled from new berries. (*J. P. C.*, June, 1875.) The oil has the aromatic properties of cubeb, but it is probably not the sole active ingredient, as it is much less pungent than the fluidextract or the oleoresin. It may, however, often be advantageously substituted for the powder, the dose to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, in the form of emulsion, or enclosed in capsules of gelatin.

Dose, five to fifteen minims (0.3–0.9 mil).

OLEUM EUCALYPTI. U. S., Br.

OIL OF EUCALYPTUS Ol. Eucalypt. [Eucalyptus Oil]

(ō'lę-um eu-ca-lyp'tī)

"A volatile oil distilled from the fresh leaves of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*) or from some other species of *Eucalyptus*, and yielding not less than 70 per cent., by volume, of eucalyptol (cineol) [$C_{10}H_{18}O$ = 154.14]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Eucalyptus is the oil distilled from the fresh leaves of Eucalyptus Globulus, *Labill.*, Eucalyptus dumosa, *A. Cunn.*, and other species of Eucalyptus, and rectified." *Br.*

Oil of Eucalyptus Globulus; Huile volatile (Essence) de Eucalyptus, *Fr. Cod.*; Eucalyptusöl, *G.*; Esencia de eucalipto, *Sp.*

Various species of the genus *Eucalyptus*, grown in Australia and Algeria, yield volatile oils in sufficient quantity to be commercial products. Probably the most important of these plants is *E. Globulus*, on account of its high cineol (eucalyptol) content. Large quantities of oil are also distilled from other species, viz., *E. odorata, E. oleosa, E. cuenfolia* and *E. dumosa.*

Oil of eucalyptus is officially described as "a colorless or pale yellow liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, and cooling taste. It is soluble in 4 volumes of 70 per cent. alcohol. Specific gravity: 0.905 to 0.925 at 25° C. (77° F.). Mix 2 mils of the Oil with 4 mils of glacial acetic acid and gradually add 3 mils of a saturated solution of sodium nitrite. When gently stirred, the mixture does not form crystals of phellandrene nitrite (*other eucalyptus oils containing large amounts of phellandrene*)." *U. S.*

"Colorless or pale yellow. Aromatic, camphoraceous odor; taste pungent, leaving a sensation of cold. Specific gravity 0.910 to 0.930; *optical rotation* –10° to +10°. Soluble in 5 parts of *alcohol* (70 per cent.). Contains not less than 55 per cent. by volume of cineol as determined by the process described under 'Oleum Cajuputi.' When 1 millilitre is mixed with 2 millilitres of *glacial acetic acid* and 5 millilitres of *petroleum spirit*, 2 millilitres of a saturated aqueous solution of *sodium nitrite* being added, and the mixture gently shaken, no crystalline precipitate forms in the upper layer (absence of oils containing much phellandrene)." *Br.*

Assay.—"Measure 10 mils of the Oil, from a pipette, into a round-bottom glass dish of 50 mils capacity, which is imbedded in finely broken ice. Add 10 mils of arsenic acid T.S. and stir until precipitation is complete. When the mixture ceases to congeal further, allow it to stand for ten minutes in the ice bath. (If at this point a hard mass is formed, add 5 mils of purified petroleum benzin, and mix the mass well before proceeding with the assay.) Then

transfer it immediately to a hardened filter paper, about 18.5 cm. in diameter, by means of a pliable horn spatula; spread it evenly over the surface of the paper and lay a second hardened filter paper over the top. Wrap several thicknesses of absorbent or filter paper around the hardened filters, and place the whole between the plates of a press and bring to bear all the pressure possible for about one minute. Change the outside absorbent papers and press again, repeating the operation, if necessary, until the eucalyptol arsenate is apparently dry, and separates readily when touched with a spatula. The pressing is not complete when a hard mass remains which is broken up with difficulty; and usually two changes of filter paper are required, pressing each time for about two minutes; if left too long in the press the compound may decompose. Now, transfer the compound completely by means of the horn spatula to a glass funnel inserted into a 100 mil cassia flask with a neck graduated to 10 mils into tenths. Wash the last portions of the precipitate into the flask with a stream of hot distilled water from a wash bottle, assisting the disintegration with a glass rod, place the flask in boiling water and rotate it until the compound is thoroughly broken up. Then add enough distilled water to cause the eucalyptol to rise into the neck of the flask, cool it to room temperature and read its volume. This volume, multiplied by 10, shows the percentage of eucalyptol (cineol) in the Oil." *U. S.*

The official method of assay of this oil for cineol content was developed by Jos. L. Turner and R. C. Holmes. (*A. J. P.*, 1915, p. 101.)

Power has modified the test for phellandrene so as to make it more delicate. According to his directions, 1 mil of the oil is mixed with 5 mils of petroleum benzin, 1 or 2 mils of a concentrated solution of sodium nitrite added, and subsequently glacial acetic acid added, a drop or two at a time, with vigorous agitation after each addition. If phellandrene is present in any considerable amount, its crystalline nitrosite, $C_{10}H_{16}(NO)NO_2$, will separate from the benzin solution. The oil from eucalyptus globulus contains *pinene,* $C_{10}H_{16}$, and *eucalyptol* (or *cineol*), $C_{10}H_{18}O$. Schimmel & Co. also state (*Ber. d. Chem. Ges.*, April, 1888) that they have obtained several of the aldehydes of the fatty series, notably valeraldehyde, and probably butyraldehyde and capronaldehyde, in their distillation of the oil from *Eucalyptus Globulus.*

The valuation of eucalyptus oil being based upon its cineol (eucalyptol) content the commercial oils from other species of eucalyptus are regarded with much less favor for medicinal purposes, because of their variable quality in this respect, and the fact that the other oils contain such constituents as phellandrene, cymene, citronellal, citral and other less known constituents. Cineol being optically inactive and high in its specific gravity communicates specific properties to such oils as contain it in large amounts by which their approximate value or their genuineness may be determined irrespective of the assay for cineol, which, of course, must be the ultimate deciding factor. There is much variation in the physical constants found in the literature of the eucalyptus oils as determined by different observers, and much work yet remains to be done upon the subject.

Eudesmol, $C_{10}H_{16}O$ (possibly a ketone), is the name given to a crystalline camphor obtained from the oil from *E. piperita;* H. G. Smith and R. T. Baker isolated this product, and later H. G. Smith read a paper upon it before the Royal Society of New South Wales. It proved to be isomeric with camphor, but chemically it is shown to have its oxygen atom combined in a different way.

Uses.—In the belief that the medicinal properties of oil of eucalyptus depend upon cineol, the Pharmacopœia rejects those oils which contain chiefly phellandrene, but as a matter of fact, we have no definite knowledge concerning the physiological action of phellandrene. Whether or not the medicinal virtues of the official oil are due entirely to its cineol is uncertain, but many prefer to use the pure eucalyptol to the oil itself.

Oil of eucalyptus is an active germicide, although surpassed in power by many of the other volatile oils. Cineol is probably a less efficient antibacterial agent than oil of eucalyptus. When taken in overdose it causes rapidity of the pulse with general excitement and restlessness, nausea, vomiting, frequently dilatation of the pupils, and symptoms of collapse. In the lower animals it reduces the arterial pressure and the bodily temperature, causes muscular weakness, irregular respiration and death from respiratory failure. It is absorbed from the intestinal tract, eliminated partially through the breath to which it imparts its odor, and also, as an oxidation product, through the urine to which it gives an odor resembling that of violets.

The oil of eucalyptus is used locally as an antiseptic, especially in the treatment of infections of the upper respiratory tract and in certain forms of *skin disease.* Internally it is used as a stimulating expectorant in *chronic bronchitis* and *tuberculosis.* In these conditions it is also frequently given by inhalation; a few drops of the oil may be added to boiling water and the mixed vapors and steam inhaled. It has been specially praised in *asthma,* given internally or preferably by inhalation by means of cigarettes, which may be made by rolling up the dried leaves, or the vapor from boiling water containing the oil may be inhaled. It is also used as a remedy against the *hookworm,* but is probably of inferior value. It possesses also some antiperiodic power and may be used in *malarial fever* when for any reason quinine or methylthionine are not available.

Dose, three to ten minims (0.2–0.6 mil), best administered in emulsion.

Off. Prep.—Unguentum Eucalypti, *Br.*

OLEUM FŒNICULI. U. S.

OIL OF FENNEL Ol. Fœnic. [Fennel Oil]

(ō'lę-ŭm fœ-nĭc'ù-lī)

"A volatile oil distilled from the ripe fruit collected from cultivated varieties of *Fœniculum vulgare* Miller (Fam. *Umbelliferæ*). If wholly or partly solidified, carefully warm the Oil until liquefied and thoroughly mix it before dispensing. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Huile volatile de Fenouil, *Fr. Cod.*; Essence de Fenouil, *Fr.*; Oleum Fœniculi, *P. G.*; Fenchelöl, *G.*

Fennel seeds yield about 2.5 per cent., or, according to Zeller, from 3.4 to 3.8 per cent., of oil. That used in this country is imported. "A colorless or pale yellow liquid, having the characteristic odor and taste of fennel. It is soluble in 8 volumes of 80 per cent. alcohol and in 1 volume of 90 per cent. alcohol, forming a solution neutral to litmus. Specific gravity: 0.953 to 0.973 at 25° C. (77° F.). The optical rotation varies from +12° to +24° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). When tested by the method under *Oleum Anisi*, with the following modifications, the congealing point of the Oil does not fall below 3° C. (37.4° F.). Cool the test tube containing the 10 mils of Oil of Fennel in a freezing mixture until the temperature has fallen to 0° C. (32° F.), and induce crystallization as directed." *U. S.*

It congeals below 10° C. (50° F.) into a crystalline mass, separable by pressure into a solid and a liquid portion, the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. It contains *anethol*, $C_{10}H_{12}O$ (a phenol-ether forming a white solid melting at 21° C. (69.8° F.)) (see *Oleum Anisi*), the latter usually in amounts of about 60 per cent., d-pinene, phellandrene, dipentene, *fenchone*, $C_{10}H_{16}O$ (a liquid ketone), chavicol, anisic aldehyde, and anisic acid. Fenchone is the constituent which when present gives the disagreeable bitter taste to many of the commercial oils. *Schimmel's Report* for April, 1897, mentions limonene as also at times present as a constituent. Umney finds that Japanese oil contains about 75 per cent. of anethol and 10 per cent. of fenchone, besides terpenes. (*Proc. A. Ph. A.*, 1897, 516.) There is reason to believe that much of the commercial oil is adulterated with oil from which the anethol or crystalline constituent has been separated; the official solidifying point not below 5° C. (41° F.) should be required. Flückiger states (*Pharm. Chem.*, 2d ed., 1888, 422) that it contains more hydrocarbon than oil of anise, and notably that from Nîmes, in Southern France, contains much less anethol, and hence has a milder and sweeter taste which is also probably due to the absence of the bitter fenshone. As found in commerce, therefore, the oil of fennel is not uniform, and a specimen examined by Montgomery did not congeal at −5.5° C. (22° F.). (See *Oleum Anisi.* It is slightly dextrogyrate.

Dose, three to five minims (0.2–0.3 mil).

Off. Prep.—Aqua Fœniculi, *U. S.*

OLEUM GAULTHERIÆ. Br.

OIL OF GAULTHERIA [Oil of Wintergreen]

(ō'lę-ŭm gâul-thē'rī-æ)

"Oil of Gaultheria is the oil distilled from the leaves of Gaultheria procumbens, *Linn.*, or from the bark of Betula lenta, *Linn.*" *Br.*

Oil of Teaberry, Oil of Partridge-berry; Huile volatile (Essence) de Winter-green, *Fr. Cod.*; Essence de Gaulthérie, *Fr.*; Wintergrünöl, Bergtheeöl, *G.*

Oil of gaultheria is no longer official in the U. S. P. IX. Under *Methylis Salicylas* the Pharmacopœia directs that oil of gaultheria and oil of betula or sweet birch may be used.

The volatile oil of gaultheria is largely obtained in the United States by distillation of the plant. It probably does not exist in the plant, but is formed by a reaction between water and a neutral principle analogous to amygdalin, to which Procter has given the name of *gaultherin*. (*A. J. P.*, xv.) This substance, which was called by Schneegans *bétulase*, probably exists in all the numerous plants which yield methyl salicylate on distillation. The oil occurs in various of our native plants, and has been detected in *Polygala paucifolia, Spiræa Ulmaria, Spiræa lobata*, and *Gaultheria chiogenes*. T. E. de Vrij found it in considerable proportion in the *Gaultheria leucocarpa* and *G. punctata*, plants which are abundant in the volcanic regions of Java (*A. J. P.*, 1879); while Bourquelot (*C. R. S. B.*, iii, 1896) detected it in *Monotropa Hypopitys*, in *Polygala Senega*, and in other species of Polygala. (See also *A. J. P.*, 1898, 412.) Much of the so-called oil of wintergreen is obtained from *Betula lenta*, which yields a product physically indistinguishable and difficult to differentiate chemically from methyl salicylate.

The still in which oil of wintergreen is distilled is generally a wooden box, about eight feet long, four feet wide, four feet high, with a copper bottom and stayed with bolts. The head of the still is copper, and connecting with this is a circular worm of the same material or of tin, placed in a barrel. The still being filled with wintergreen to within about twelve inches of the top, a sufficient quantity of water is added, and this is allowed to macerate from ten to twelve hours. The fire being started, the distillation commences, and continues for about eight hours; but during the first two or three hours ninety per cent. of the oil has passed over. For collecting the distillate, most of the distillers use a wide-mouthed bottle, fitted with a large cork having two holes. A small funnel is put into one of the holes, so that the beak is below the shoulder of the receiving vessel, and connected with the other hole is a suitable pipe

forming an outlet. The oil and the water separate, the oil going to the bottom, and the water passes into a larger receptacle, where it is reserved for a subsequent operation (cohobation).

Occasionally the oil is very highly colored, and the wholesale dealers have three ways of "cleaning" it—redistillation, filtration, and decolorization. In the last method the oil to be decolorized is put into a bottle, crystals of citric acid are added, and the whole is allowed to stand, agitating occasionally, until the oil is colorless, or nearly so.

Oil of gaultheria when freshly redistilled is nearly colorless, but as found in commerce has a brownish-yellow or reddish color. The U. S. P. VIII described it as "a colorless or almost colorless liquid, having a characteristic, strongly aromatic odor, and a sweetish, warm, and aromatic taste. Specific gravity: 1.172 to 1.180 at 25° C. (77° F.). Boiling point: 218° to 221° C. (424.4°–429.8° F.). It is slightly lævogyrate, up to –1° in a 100 Mm. tube, at 25° C. (77° F.). In other respects it has the same properties as, and conforms to the reactions and tests given under, *Methylis Salicylas.*"

"Colorless or nearly colorless. Strong, characteristic odor; taste pungent. Specific gravity 1.180 to 1.187; *optical rotation* at 25° C. (77° F.) 0° to –1°; *refractive index* 1.537 to 1.539. Soluble in 6 parts of *alcohol* (70 per cent.) at 25° C. (77° F.). Contains not less than 99 per cent. of *esters*, calculated as methyl salicylate, $CH_3C_7H_5O_3$." *Br.*

It is stated to have been largely adulterated with chloroform. This and other impurities are to be detected by a comparison of the specific gravities and boiling points, or by fractional distillation. It is readily soluble in alcohol. When heated to about 80° C. (176° F.), the oil should not yield a colorless distillate having the characteristics of chloroform or of alcohol. (*A. J. P.*, 1873, p. 521.) Another distinguishing property is that in aqueous solution it gives a purple color with ferric salts. Oil of sassafras may be detected by the separation of a deep-red resinous mass on treatment with nitric acid in the cold. Japanese oil of camphor and other light volatile oils used as adulterants can be detected by simply dropping the suspected oil in water; if pure, it sinks in a few seconds; if adulterated, some minutes are required. Cahours states that one-tenth of the oil consists of a peculiar hydrocarbon, which he called *gaultherilene*, and the remaining nine-tenths of *methyl salicylate*. (*A. J. P.*, xiv, 211, xv, 241.) Trimble and Schroeter (*A. J. P.*, 1889, 398) found that the amount of the hydrocarbon *gaultherilene* was much less than that stated by Cahours—in fact, only 0.3 per cent. By analysis and vapor density determination they fixed its formula as $C_{15}H_{24}$, but they state that it may consist of a solid and a liquid portion. Power and Kleber (*Fritzsche Bros. Circ.*, No. 7) assert that this hydrocarbon belongs to the paraffin series, and state that it is probably *triacontane*, $C_{30}H_{62}$. They also find in the oil an aldehyde or ketone, with an odor like œnanthic aldehyde, an apparently secondary alcohol, $C_6H_{12}O$, and an ester, $C_{14}H_{24}O_2$. To the alcohol and the ester are attributed the characteristic odor of the oil. True oil of gaultheria contains about 99 per cent. of methyl salicylate. *Synthetic oil of wintergreen* is now extensively manufactured and used instead of the natural oil. For a process by H. T. Thayer, see *A. J. P.*, 1895, 244. (See *Methylis Salicylas*, p. 695.)

Uses.—The therapeutic properties of this oil are precisely the same as those of *Methyl Salicylate.*

Dose, ten to twenty minims (0.6–1.3 mils).

OLEUM GOSSYPII SEMINIS. U .S.

COTTONSEED OIL Ol. Gossyp. Sem. [Cotton Seed Oil]

(ō'lę-ŭm gŏs-sŷp'ĭ-ī sĕm'ĭ-nĭs)

"A fixed oil obtained from seeds of cultivated varieties of *Gossypium herbaceum* Linné, or of other species of *Gossypium* (Fam. *Malvaceæ*). Preserve it in well-closed containers." *U. S.*

Oleum Gossypii; Cotton Oil; Huile de Semences de cotonnier, *Fr.*; Baumwollsamenöl, Bauməl, *G.*

This fixed oil has no other medicinal properties than those of a bland neutral oil, and has been introduced especially on account of its use in official liniments. The amount of cottonseed produced in 1914 was 7,186,000 tons, of which 5,779,665 was worked up into its various products. The oil obtained was 229,260,000 gallons. The oil cake is largely exported to England, where it is used as food for cattle, and the oil to France, Italy, and other olive growing countries of Europe, whence much of it returns to us mixed with olive oil. The exportation of cottonseed oil for 1915 amounted to 318,366,525 lbs., valued at $21,872,948. For a description of the process of extraction, see *A. J. P.*, 1896, 42; also 1898, 497. Among the recent improvements in the purification of cottonseed oil are the processes of Chisholm using silicate of soda for clarifying and of Baskerville using a paper pulp or cellulose fiber.

This oil is obtained by expression from the seeds previously deprived of their shells. In this state they yield two gallons of oil to the bushel. As first obtained, it is thick and turbid, but it deposits a portion of its impurities on standing.

The oil is clarified by first boiling it with water, to separate the mucilage, and then heating it with a weak solution of sodium hydroxide, which combines with the coloring matter and saponifies a part of the oil. The mixture becomes filled with black flocks, which deposit on standing and leave the oil but slightly colored. The loss in refining is usually from 4 to 7½ per cent., but occasionally amounts to 12 or 15.

Besides this crude oil, there are three varieties in commerce, more or less purified, recognized as the *clarified*, the *refined*, and the *winter bleached*. The last mentioned is of a pale straw-color, a mild peculiar odor, and a bland sweetish

taste, not unlike that of almond oil. The oil is used in the preparations of woollen cloth and morocco leather, and for oiling machinery. It has been found to be an excellent substitute for almond and olive oils in most pharmaceutical preparations in which they are employed, but it does not answer so well in the formation of lead plaster. Citrine ointment carefully prepared with it, too great heat being avoided, retains a rich orange color and proper unctuous consistence.

Properties.—It is officially described as "a pale yellow, oily liquid, odorless or nearly odorless, and having a bland taste. It is slightly soluble in alcohol; miscible with ether, chloroform, petroleum benzin, or carbon disulphide. Specific gravity: 0.915 to 0.921 at 25° C. (77° F.). On cooling the Oil to a temperature below 12° C. (53.6° F.) particles of solid fat separate. At about 0° to –5° C. (32°–23° F.) the Oil becomes nearly or quite solid. Add sulphuric acid (specific gravity 1.6 to 1.7) to the Oil, preferably diluted with carbon disulphide; a reddish-brown color is rapidly produced. Mix 2 mils of the Oil in a test tube with 2 mils of a mixture of equal volumes of amyl alcohol and a 1 per cent. solution of sulphur in carbon disulphide, and immerse the test tube to one-third of its depth in a boiling, saturated aqueous solution of sodium chloride; a red color develops in from ten to fifteen minutes. Saponification value: not less than 190 nor more than 198 (see Part III, Test No. 9). Iodine value: not less than 105 nor more than 114 (see Part III, Test No. 8)." *U. S.*

As this oil is much used for adulterating olive oil, tests to distinguish it are very desirable. The test most depended upon is that known as *Halphen's test,* a mixed solution of amyl alcohol and carbon disulphide containing 1 per cent. of dissolved sulphur. This is given in the official test. It is stated that cotton seed oil, which has been heated to 250° C. (482° F.) no longer gives many of the characteristic reactions for detecting the oil.

Dose, two to six fluidrachms (7.5–22.5 mils).

Off. Prep.—Linimentum Camphoræ, *U. S.;* Linimentum Ammoniæ, *U. S.*

OLEUM GRAMINIS CITRATI. Br.

OIL OF LEMON GRASS

(ō'lę-ŭm grā'mĭ-nĭs cĭ-trā'tī)

"Oil of Lemon Grass is the oil distilled from Cymbopogon citratus, *Stapf,* and Cymbopogon flexuosus, *Stapf.*" *Br.*

Lemon-grass Oil.

The *East Indian Lemon Grass Oil* comes from Malabar, Cochin, India and the Malay Peninsula. A product of the *C. citratus* comes from Ceylon, Burma and adjacent countries, as well as from Mexico and the West Indies.

It is officially described in the British Pharmacopœia, 1914, as "Dark yellow. Odor resembling that of verbena. Specific gravity 0.880 to 0.905; *optical rotation* –3° to +3°. Contains not less than 70 per cent. of aldehydes as determined by the process described under 'Oleum Cinnamomi." *Br.*

The chief aldehyde present is citral, of which it contains 70 to 85 per cent. Linalool, geraniol and methyl peptenone are also reported present in small amounts. The principal use of the oil is in perfuming cheap soaps. (See also *Oil of Citronella,* Part II.)

Oil of lemon grass is sometimes used in Eastern countries as a carminative and stimulant in *doses* of one-half to three minims (0.03–0.2 mil). Its chief use is in perfumery.

OLEUM JUNIPERI. U. S., Br.

OIL OF JUNIPER Ol. Junip. [Juniper Oil, Oil of Juniper Berries]

(ō'lę-ŭm jū-nĭp'ę-rī)

"A volatile oil distilled from the ripe fruit of *Juniperus communis,* Linné (Fam. *Pinaceæ*). Preserve it in well-stoppered, amber-colored bottles in a cool place, protected from light." *U. S.* "Oil of Juniper is the oil distilled from the ripe fruit of Juniperus communis, *Linn.,* and rectified." *Br.*

Oleum Fructus (vel Baccæ) Juniperi; Huile volatile (Essence) de Genièvre, *Fr.;* Oleum Juniperi, *P. G.;* Wachholderöl, Wachholderbeeröl, *G.;* Essenza di ginepro, *It.*

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained 1 per cent. The highest quantity given in the table of Recluz is 2.34, the lowest 0.31 per cent. Zeller gives as the product of the fresh ripe fruit 1.3 per cent., of that a year old 0.86 per cent. The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. "A colorless or faintly green or yellow liquid, having the characteristic odor and taste of juniper fruit. It is soluble in 4 volumes of alcohol with not more than a slight cloudiness. Specific gravity: 0.854 to 0.879 at 25° C. (77° F.). The optical rotation varies from 0° to –15°, in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)." *U. S.*

"Colorless or pale yellowish-green. Odor that of the fruit; taste warm, aromatic and bitter. Specific gravity 0.862 to 0.890, increasing with age; *optical rotation* –3° to –15°; *refractive index* at 25° C. (77° F.) 1.472 to 1.488. Soluble, when freshly distilled, in 4 parts of a mixture of equal volumes of *alcohol* (90 per cent.) and *absolute alcohol,* becoming less soluble with age." *Br.*

According to Flückiger (*Pharm. Chem.,* 2d ed., 1888, 402), it is composed essentially of two hydrocarbons, the more abundant of which, boiling at 160° C. (320° F.), has been shown

by Wallach to be pinene, $C_{10}H_{16}$. Above 175° C. (347° F.) another oil is obtained, which seems to be cadinene, $C_{15}H_{24}$. It also contains a small amount of an ester to which the peculiar juniper-like odor and taste was supposed to be due, but this cannot be the case, as the odor persists after the complete saponification of the small amount of ester. *Juniper camphor* is also present, its melting point is 165° to 166° C. (329°–330.8° F.). Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture being less than that of the unadulterated oil of juniper.

Uses.—Oil of juniper is occasionally used as a carminative in *intestinal flatulence,* but is more popularly employed for its diuretic effect. Because of its local irritant action it should never be used when there is an active inflammatory process in the kidney or urinary tract. It is frequently combined with potassium bitartrate. To it gin owes its peculiar flavor as well as its diuretic effects.

Dose, two to ten minims (0.12–0.6 mil).

Off. Prep.—Spiritus Juniperi, *U. S., Br.;* Spiritus Juniperi Compositus, *U. S.;* Acetum Aromaticum, *N. F.*

OLEUM LAVANDULÆ. U. S., Br.

OIL OF LAVENDER Ol. Lavand. [Oleum Lavandulæ Florum, U.S. P. VIII]

(ō'lę-ŭm lą-văn'dŭ-læ)

"A volatile oil distilled from the fresh flowering tops of *Lavandula vera* De Candolle (*Lavandula officinalis* Chaix, *Lavandula spica* Linné) (Fam. *Labiatæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from the flowers of Lavandula vera, *DC.*" *Br.*

Huile volatile de Lavande officinale, *Fr. Cod.;* Essence de Lavande, *Fr.;* Oleum Lavandulæ, *P. G.;* Lavendelöl, *G.;* Essenza di lavanda, *It.;* Esencia de espliego, *Sp.*

This oil is usually distilled from the flowers and flower stems conjointly, though of finer quality when obtained from the former exclusively. Dried lavender flowers are said to yield from 1 to 1.5 per cent. of oil. According to Zeller, the fresh flowers yield 1.03, the dried 4.3, the whole fresh herb in flower 0.76 per cent. It is stated that the lavender produced by an acre of ground under cultivation will yield from 10 to 12 pounds of the oil. (*P. J.,* 1864, p. 257.) The oil is very fluid, of a lemon-yellow color, with the fragrance of the flowers and an aromatic, burning taste. That met with in commerce has the sp. gr. 0.898 at 20° C. (68° F.), which is reduced to 0.877 by rectification (Berzelius), or 0.886 (Buignet). It is lævogyrate. According to Brande, the sp. gr. of the oil obtained from the whole herb is 0.9206. Alcohol of 0.830 dissolves oil of lavender in all proportions, that of 0.877 only 42 per cent. (Berzelius.) Proust states that when allowed to stand in imperfectly stoppered bottles it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. This has been found by Dumas to have the same point of volatilization and the same composition as true camphor, but to differ in the total want of rotatory power. It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a higher price. "Oil of Lavender is a colorless or yellow liquid, having the characteristic odor and taste of lavender flowers. It is soluble in 3 volumes of 70 per cent. alcohol. Specific gravity: 0.875 to 0.888 at 25° C. (77° F.). The optical rotation varies from –1° to –10° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). When shaken in a narrow glass cylinder with an equal volume of distilled water, its volume does not diminish (*alcohol*). Shake 20 mils of the Oil with 40 mils of 5 per cent. alcohol and, when the mixture has cleared, withdraw 30 mils of the alcoholic solution. Neutralize this with half-normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator, then add 5 mils of half-normal potassium hydroxide V.S. and heat the mixture on a water-bath, under a reflux condenser, during one hour. Not less than 4.7 mils of half-normal hydrochloric acid V.S. is required for neutralization (*foreign esters*)." *U. S.*

"Pale yellow or yellowish-green. Odor that of the flowers; taste pungent, slightly bitter. Specific gravity 0.883 to 0.900; *optical rotation* –3° to –10°. Soluble in 4 parts of *alcohol* (70 per cent.). Contains from 7 to 11 per cent. of *esters* (English oil), or not less than 30 per cent. of *esters* (foreign oil), calculated as linalyl acetate, $C_{10}H_{17}C_2H_3O_2$." *Br.*

The principal constituent is an alcohol, $C_{10}H_{18}O$, identical with the linalool. Besides linalool, lavender oil contains linalyl acetate (from 30 to 45 per cent. in the oil from French flowers, and from 7 to 10 per cent. in the oil from English flowers), the butyric ester of the same alcohol, geraniol, a very small amount of cineol (more in the English than in the French oil), and sometimes traces of pinene, limonene, and a sesquiterpene.

Oil of Spike is procured from the broad leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Cavanilles. Its odor is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes. The oil of spike contains about 30 per cent. of cineol and but small quantities of esters. Oil of lavender is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of *nervous languor* and *headache.*

Dose, from one to five minims (0.06–0.3 mil).

Off. Prep.—Spiritus Lavandulæ, *U. S., Br.;* Tinctura Lavandulæ Composita, *U. S., Br.;* Acetum Aromaticum, *N. F.;* Spiritus Odoratus, *N. F.*

OLEUM LIMONIS. U. S., Br.

OIL OF LEMON Ol. Limon. [Lemon Oil]

(ō'lę-ŭm lĭ-mō'nĭs)

"A volatile oil obtained by expression from the fresh peel of the ripe fruit of *Citrus medica Limonum* (Risso) Hooker filius (Fam. *Rutaceæ*), and yielding not less than 4 per cent. of the aldehydes from Oil of Lemon, calculated as citral [$C_{10}H_{16}O = 152.13$]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light. Oil of Lemon having a terebinthinate odor is not to be dispensed." *U. S.* "Oil of Lemon is the oil obtained from Lemon Peel by various methods of expression." *Br.*

Oleum Limonum; Huile volatile de Citron, *Fr. Cod.*; Essence de Citron, *Fr.*; Oleum Citri, *P. G.*; Citronenöl, *G.*; Olio de limone, *It.*; Esencia de limon, *Sp.*

The exterior rind of the lemon abounds in a volatile oil, which, being contained in distinct cells, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and kept in stoppered bottles. By a similar process, the oil called by the French *huile de cédrat* is procured from the citron. (See *Oil of Bergamot*, Part II, and *Succus Limonis.*) These oils may also be obtained by distillation, but thus procured, though clearer, and, in consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavor of the fruit, and the mode by expression is generally preferred. A third method of separating the oil, used in Calabria and Sicily, is to put the grated rind into hot water and skim off the oil as it rises to the surface. (*A. J. P.*, 1868, p. 27.) The method employed to obtain the finest oil is, however, that known as the écuelle process. The écuelle is an instrument usually made of tinned copper, bowl-shaped, and armed with concentric rows of short spikes. Attached to the bottom of the bowl is a hollow handle, closed at the bottom. This acts as a reservoir for the oil as the fruit is rubbed by the workmen over the sharp teeth. The oils are brought from Italy, Portugal, or Southern France.

The oils of lemons and oranges, as well as those of the other *Aurantiaceæ*, will keep indefinitely upon admixture with a small proportion of alcohol (one ounce to a pound of the oil). When wanted for use, a quantity of water equal to that of alcohol, added to the mixture, will unite with the alcohol, and subside, leaving the oil free of the alcohol for all practical purposes. (Carl Früh, *A. J. P.*, 1871, 201.) E. J. Parry (*Ch. & Dr.*, 1913, p. 378) discusses at some length the relative advantages of terpeneless and sesquiterpeneless oils and normal oils. The ordinary terpeneless oils contain from 42 to 45 per cent. of citral, while those that are sold as sesquiterpeneless contain from 65 to 72 per cent. citral. He states that the latter products lack the sweetness and softness of odor of those containing less citral, the overpowering odor of the latter constituent destroying the balance of harmony in the odor of the oil. He states that users of these products claim to get the best results from oils containing slightly less than 40 per cent. of citral and from which the whole of the terpenes have not been removed. The characters of the commercial terpeneless oils are as follows: sp. gr. at 15° C. (59° F.), 0.8935 to 0.899; optical rotation, −5° to −8° 30′; refractive index, 1.4810; citral, 42 to 48 per cent. The sesquiterpeneless oils are slightly higher in specific gravity, lower in optical rotation and always run above 65 per cent. of citral.

The great extent of the production and export of Sicilian and Calabrian essential oils (lemon, orange, bergamot, etc.) may be seen from the Italian official statistics, according to which the number of trees producing in 1896 was 17,084,569, yielding 3,337,000,000 fruits. Of these 1,897,000,000 were exported, leaving 1,439,555,000 fruits for home consumption inclusive of those used in the manufacture of essences. (*Schim. Rep.*, Oct., 1897, 23.)

Parry (*Schim. Rep.*, Apr., 1912, p. 78) reports several shipments of lemon oil which upon investigation were found to be adulterated with Greek turpentine oil. They were noted by their low optical rotation, + 50° to + 54°, and their low citral content, 3.3 to 4.1 per cent.

Properties.—Oil of lemon is "a pale yellow or greenish-yellow liquid, having the characteristic odor and taste of lemon. Specific gravity; 0.851 to 0.855 at 25° C. (77° F.). Refractive index: 1.4744 to 1.4755 at 20° C. (68° F.) (see Part III, Test No. 22). The optical rotation varies from + 57° to + 64° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). The angle of rotation of the first 10 per cent. of the distillate, obtained as directed under *Oleum Aurantii*, is not more than 5 degrees less than that of the original Oil. The refractive index of this first 10 per cent. of distillate is not less than 0.002 nor more than 0.0027 lower than that of the original oil." *U. S.*

"Pale yellow. Volatile; odor that of lemons; taste warm, afterwards slightly bitter. Specific gravity 0.857 to 0.860: *optical rotation* + 58° to + 64°; *refractive index* at 25° C. (77° F.) 1.473 to 1.476. Contains not less than 4 per cent. by weight of aldehydes, calculated as citral, $C_{10}H_{16}O$, as determined by the following process." *Br.*

Assay.—"Introduce about 15 mils of Oil of Lemon into a tared 300 mil flask and note the exact weight; add 10 mils of an alcoholic solution of phenylhydrazine (1 in 10) (not darker in color than pale yellow), and allow it to stand for one-half hour at room temperature. Then add a few drops of methyl orange T.S. and neutralize the liquid exactly by the cautious addition of half-normal hydrochloric acid V.S. If difficulty is experienced in detecting the end point of the reaction, continue the titration until the solution is distinctly acid, transfer it to a

separatory funnel and draw off the alcoholic portion. Now wash the Oil with distilled water, adding the washings to the alcoholic solution, and titrate the latter with half-normal potassium hydroxide V.S. Carry out a blank test identical with the foregoing, except that the Oil of Lemon is omitted, and note the amount of half-normal hydrochloric acid V.S. consumed. Subtract the number of mils of half-normal potassium hydroxide V.S. from the number of mils of half-normal hydrochloric acid V.S. consumed in the original test and this result from the corresponding number of mils required in the blank test; each mil of this difference corresponds to 0.076 Gm. of aldehydes, calculated as citral. It shows, when calculated from the weight of Oil taken, not less than 4 per cent. of aldehydes from Oil of Lemon, calculated as citral." *U. S.*

"To 20 grammes of the Oil contained in a flask add 20 millilitres of *N/2 solution of hydroxylamine hydrochloride,* 8 millilitres of *N/1 alcoholic solution of potassium hydroxide* and 20 millilitres of *alcohol* (90 per cent.). Attach a reflux condenser, boil for thirty minutes, cool, and dilute with 250 millilitres of *water,* rinsing the condensing tube into the flask with part of this quantity. Neutralise the solution thus obtained with *N/1 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator, and then titrate with *N/2 solution of sulphuric acid, solution of methyl orange* being used as indicator. Repeat the experiment, omitting the Oil of Lemon. The quantity of *N/2 solution of sulphuric acid* required in the second experiment exceeds that required in the first experiment by not less than 10.5 millilitres (presence of not less than 4 per cent. of aldehydes, calculated as citral, $C_{10}H_{16}O$)." *Br.*

Oil of lemon contains a small amount of pinene, with dextrogyrate limonene, about 7 to 8 per cent. of *citral,* $C_{10}H_{16}O$, an aldehyde yielding geraniol upon reduction, and a small amount of *citronellal,* $C_{10}H_{18}O$, also an aldehyde. Pinene, phellandrene, higher aldehydes, as octyl and nonyl, terpineol and geranyl acetate have also been reported in small amounts. Of these the citral is the constituent to which the oil chiefly owes its aroma and value. Umney and Swinton (*P. J.,* 1898, 196) state that citral, citronellal, and an ester of geraniol are all necessary to form the true odor of oil of lemon. Citral boils under normal atmospheric pressure at from 228° to 229° C. (442.4°–444.2° F.) without decomposition if pure, and, like aldehydes, forms stable compounds with alkaline bisulphites. Schimmel & Co. now prepare the citral in a pure state, and recommend its use for enriching the ordinary oil of lemon.

Oil of lemon is often adulterated by the fixed oils and by alcohol, and sometimes with purified oil of turpentine, which is difficult of detection from its similar composition and specific gravity except with the polariscope. One of the tests for the presence of this oil is the terebinthinate odor produced when the adulterated oil is evaporated from heated paper; the official quantitative test defining the percentage of citral will be of service in detecting these adulterations. The most dangerous adulteration of oil of lemon is the use of *citrene,* the terpene left after the extraction of citral from oil of lemon which has been used in making terpeneless oil. Oil of lemon procured by expression is apt to precipitate and to undergo chemical change. J. S. Cobb has found no method so effectual to obviate this result, and at the same time to retain unimpaired the flavor of the oil, as to shake it with a little boiling water and allow the mixture to stand. A mucilaginous matter separates, and floats on the surface of the water, from which the purified oil may be decanted. (*Ann. Pharm.,* ii, 86.) The best method of preservation is to add 10 per cent. of a bland fixed oil such as olive or cottonseed, which must subsequently be allowed for in measuring the oil for use.

Adulteration of Lemon Oil with Pinene.—In consequence of some seizures of lemon oil alleged to be adulterated with turpentine, in 1906, a number of importers stated their belief that pinene was normally present in appreciable amounts in some lemon oils. In consequence of this the U. S. Dept. of Agriculture undertook a special investigation of the subject, sending a trained observer and analyst to the producing countries, and published the results of the investigation in a special bulletin called "Circular 46, by E. M. Chace." The investigation showed conclusively that lemon oil shows no appreciable amount of pinene.

Spirit of Lemon (Spiritus Limonis, *U. S.* 1890) is no longer official. It was made by dissolving 50 mils of oil of lemon in 900 mils of deodorized alcohol, to which 50 Gm. of freshly grated lemon peel were added, the whole macerated for twenty-four hours, filtered, and enough deodorized alcohol added through the filter to make the whole measure 1000 mils.

Uses.—The oil of lemon is much less active than most of the other official volatile oils, and is used almost exclusively for its flavoring properties.

Dose, two to five minims (0.12–0.3 mil).

OLEUM LINI. U. S., Br.

LINSEED OIL. Ol. Lini. [Oil of Flaxseed Raw Linseed Oil]

(ō'lē-ŭm lī'nī)

"A fixed oil obtained from Linseed. Preserve it in well-stoppered containers. Linseed Oil which has been 'boiled' must not be used nor dispensed." *U. S.* "Linseed Oil is the oil expressed from Linseed." *Br.*

Huile de Semence de Lin, *Fr.;* Oleum Lini, *P. G.;* Leinöl, Leinsamenöl, *G.;* Olio di lino, *It.;* Aceite de linaza, *Sp.*

This oil is obtained by expression from the

seeds of *Linum usitatissimum,* or common flax, which, according to Berjot, contain 34 per cent. (*J. P. C.,* April, 1863, p. 277.) In its preparation on a large scale, the seeds are usually roasted before being pressed, in order to destroy the gummy matter contained in their coating. The oil is thus obtained more free from mucilage, but more highly colored and acrid than when procured by cold expression. For medicinal use, therefore, it should be prepared without heat, and, as it is apt to become rancid quickly on exposure, it should be used as soon after expression as possible. It may, however, be rendered sweet again by agitation with warm water, rest, and decantation. It is said to be obtained purer and in larger proportion by treating the crushed seeds with carbon disulphide than by expression. (*A. J. P.,* xxvi, 265.)

Oil of flaxseed is "a yellowish, oily liquid, having a peculiar odor and a bland taste. When exposed to the air, it gradually thickens, darkens in color, and acquires a strong odor and taste. It is slightly soluble in alcohol, miscible with ether, chloroform, petroleum benzin, carbon disulphide, or oil of turpentine. Specific gravity: 0.925 to 0.935 at 25° C. (77° F.). It is not more than slightly acid to litmus paper which has previously been moistened with alcohol (*free acid*). Linseed Oil when spread in a thin layer on a glass plate and allowed to stand in a warm place is gradually converted into a hard, transparent resin (*non-drying oils*). To 10 mils of the Oil add 3 Gm. of potassium hydroxide, 10 mils of alcohol and 10 mils of distilled water, and heat the mixture on a water bath with frequent agitation, until a clear solution results. The addition of 100 mils of distilled water to this solution yields a clear liquid free from oily drops (*mineral or rosin oils*). Warm 2 mils of the Oil with frequent agitation in a test tube with an equal volume of glacial acetic acid, and, after cooling, add to the mixture 1 drop of sulphuric acid. A greenish color is produced (a violet color under these circumstances indicates the presence of *rosin or rosin oils*). Saponification value: not less than 187 nor more than 195 (see Part III, Test No. 9). Iodine value: not less than 170 (see Part III, Test No. 8)." *U. S.*

"Yellowish-brown. Characteristic odor; taste bland. Specific gravity 0.930 to 0.940; *saponification value* 187 to 195; *iodine value* not less than 170; *acid value* not more than 3.0; *unsaponifiable matter* not more than 1.0 per cent.; *refractive index* at 40° C. (104° F.) 1.4725 to 1.4748. Does not congeal at temperatures higher than –20° C. (–4° F.). Gradually thickens on exposure to the air, forming, when spread in thin layers, a hard transparent varnish. A mixture of 2 millilitres of the Oil with an equal volume of *acetic anhydride,* warmed and shaken, and then cooled to 15.5° C. (60° F.), is not colored violet by the addition of 2 drops of a cooled mixture of 2 parts by weight of *sulphuric acid* and 1 part by weight of *water* (absence of resin and resin oils)." *Br.*

It has the property of drying or becoming solid on exposure to the air, acquiring during the process a strong odor and taste, and increasing as much as 12 per cent. of its weight, owing to the formation of *linoxyn* by atmospheric oxidation. The drying property resides in a constituent which, to distinguish it from the olein of the non-drying oils, is named *linolein,* and is the glyceride of *linoleic acid.* Linseed oil contains about 10 to 15 per cent. of glycerides of solid fatty acids, palmitic, myristic, and stearic, and 85 to 90 per cent. of liquid glycerides. Hazura (*J. Soc. Chem. Ind.,* 1888, 506) states that the liquid fatty acids consist of about 5 per cent. of oleic acid, $C_{18}H_{34}O_2$, 15 per cent. of *linoleic acid,* $C_{18}H_{32}O_2$, 65 per cent. of *isolinolenic acid,* $C_{18}H_{30}O_2$, and 15 per cent. of *linolenic acid,* $C_{18}H_{30}O_2$. Boiled with litharge, red lead, manganese dioxide, and other so-called "driers," it absorbs oxygen still more rapidly, and gains 14 per cent. in weight. Its acridity is owing to the presence of a small proportion of an acrid oleoresin. From its drying property, it is useful in painting and in making printers' ink and in linoleum and oil cloth manufacture. The chief adulteration of linseed oil is with mineral oils and rosin oil. For their detection, see official tests already given.

It is said that crude cod liver oil has been used for the adulteration of the oil of flaxseed, especially where the latter is intended for preparing printers' ink. Aug. Morell detects the adulteration by the following method. Take 10 parts by weight of the suspected oil, mix it in a small cylindrical glass tube with 3 parts of crude nitric acid, agitate the mixture well, and allow it to rest. If cod liver oil be present, the oily layer at top will assume a dark-brown to blackish-brown color, while the acid at bottom will vary from bright orange to orange or dark yellow. So little as 3 per cent. of cod liver oil may thus be detected. If the flaxseed oil be pure, it will become, during the agitation, first sea green, and afterwards dirty greenish-yellow, the acid being bright yellow. The prohibition of the use of boiled linseed oil for medicinal purposes has its origin in the fact that much of the boiled linseed oil of commerce contains a compound of lead or manganese as a drying agent. Instances are on record where lead-containing boiled linseed oils caused the death of cattle to which the oil had been administered.

Uses.—The oil is laxative in the dose of a fluidounce (30 mils), but, on account of its disagreeable taste, is seldom given internally. It has, however, been highly recommended as a cure for *piles,* in the dose of two fluidounces (60 mils) of the fresh oil, morning and evening. It is sometimes added to purgative enemata. Particular care must be observed not to use boiled linseed oil for any medicinal purposes, as the latter frequently contains compounds of lead which give it poisonous properties.

Dose, one to two fluidounces (30–60 mils).

Off. Prep.—Linimentum Calcis, *U. S.;* Ceratum Resinæ Compositum, *N. F.*

OLEUM MENTHÆ PIPERITÆ. U. S., Br.

OIL OF PEPPERMINT **Ol. Menth. Pip.** [Peppermint Oil]

(ō'lę-ŭm mĕn'thæ pīp-ę-rī'tæ)

"A volatile oil distilled from the flowering plant of *Mentha piperita* Linné (Fam. *Labiatæ*), rectified by steam distillation, and yielding not less than 5 per cent. of esters, calculated as menthyl acetate [$C_{10}H_{19}C_2H_3O_2 = 198.18$], and not less than 50 per cent. of total menthol [$C_{10}H_{19}OH = 156.16$], free and as esters. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Oil of Peppermint is the oil distilled from fresh flowering peppermint, Mentha piperita, *Sm.*, and rectified, if necessary." *Br.*

Huile volatile de Menthe poivrée, *Fr. Cod.*; Essence de Menthe poivrée, *Fr.*; Oleum Menthæ piperitæ, *P. G.*; Pfeffermünzöl, *G.*; Essenza di menta, *It.*; Esencia de menta piperita, *Sp.*

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. Zeller gives as the product of the fresh herb, from 0.37 to 0.68 per cent., of the dried 1.14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the States of Michigan, Indiana, and New York. For a valuable account of its method of production in Michigan, by A. M. Todd, see *A. J. P.*, 1888, 328. The oil is also largely produced in Japan. (See illustrated paper, *C. D.*, 1896, 601.) Gildemeister and Hoffmann (*Aetherische Oele*, p. 836) estimate the world's production of peppermint oil at 175,000 kilos, of which the United States furnishes 90,000 kilos, and Japan 70,000 kilos. It is officially described as "a colorless liquid, having a strong odor of peppermint, and a pungent taste, followed by a sensation of cold when air is drawn into the mouth. It is soluble in 4 volumes of 70 per cent. alcohol, showing not more than slight opalescence and no separation of oil globules. Specific gravity: 0.896 to 0.908 at 25° C. (77° F.). The optical rotation varies between –23° and –33° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). Distil about 1 mil from 25 mils of the Oil and pour the distillate on 5 mils of mercuric chloride T.S.; a white film does not form at the zone of contact within one minute (*dimethyl sulphide* found in non-rectified oils)." *U. S.*

"Colorless, pale yellow, or greenish-yellow. Odor that of peppermint herb; taste pungent and aromatic, followed by a sensation of cold. Specific gravity 0.900 to 0.920; *optical rotation* –20° to –35°. Soluble in 4 parts of *alcohol* (70 per cent.). Contains not less than 50 per cent. of total *alcohols*, free and combined, calculated as menthol, $C_{10}H_{20}O$, and not less than 5 per cent. of *esters*, calculated as menthyl acetate, $C_{10}H_{19}C_2H_3O_2$." *Br.*

"Assay for Esters.—Introduce 10 mils of Oil of Peppermint into a tared flask and note the exact weight. Add 25 mils of half-normal alcoholic potassium hydroxide V.S., connect the flask with a reflux condenser, and boil the mixture during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator. Subtract the number of mils of half-normal sulphuric acid V.S. required from the 25 mils of half-normal alcoholic potassium hydroxide V.S. taken, multiply the difference by 9.909, and divide the product by the weight of the Oil of Peppermint taken to find the percentage of menthyl acetate.

"Assay for Total Menthol.—Introduce 10 mils of the Oil into a flask provided with a ground-glass tube-condenser (acetylization flask), add 10 mils of acetic anhydride and about 1 Gm. of powdered anhydrous sodium acetate, and boil the mixture gently during one hour. Allow it to cool, wash the acetylized oil with distilled water, and afterwards with sodium carbonate T.S., diluted with an equal volume of distilled water, until the mixture is slightly alkaline to phenolphthalein T.S., and then dry it with the aid of fused calcium chloride, and filter. Transfer 5 mils of the dry acetylized oil to a tared 100 mil flask, note the exact weight, add 50 mils of half-normal alcoholic potassium hydroxide V.S., connect the flask with a reflux condenser, and boil the mixture during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator, and calculate the percentage of menthol present by the following formula:

$$\text{Percentage of menthol} = \frac{A \times 7.808}{B - (A \times 0.021)}$$

In which A is the result obtained by subtracting the number of mils of half-normal sulphuric acid V.S. required in the above titration from the number of mils of half-normal alcoholic potassium hydroxide V.S. originally taken, and B is the weight of acetylized oil taken." *U. S.*

Upon cooling or long standing it deposits a stearopten. Berzelius stated that at –13.3° C. (–8° F.) the oil deposits small capillary crystals. These are called *peppermint camphor* or *menthol*, $C_{10}H_{19}OH$. (See *Menthol*, p. 694.) A complete summary of the composition of American peppermint oil, on the authority of Power and Kleber, given in *Schimmel & Co.'s Report* for April, 1897, shows the following constituents: acetaldehyde, isovaleraldehyde, dimethyl sulphide, amyl alcohol, isovaleric acid, pinene, phellandrene, cineol, limonene, *menthone*, $C_{10}H_{18}O$, menthol, the acetate and isovalerate of menthyl, *a-lactone*, $C_{10}H_{16}O_2$, and cadinene. Menthol, its oxidation product menthone, and the acetic and isovaleric esters of menthyl have been identified as present in English and French peppermint oils, which probably also contain most of the other constituents mentioned above. Menthol and its esters are regarded as the main constituents of oil of peppermint and an official assay for determining

the percentage of menthol will be found above. The dimethyl sulphide and some of the other constituents are objectionable from the flavoring standpoint, and are largely removed by the steam distillation which is required for rectification. The polariscope has been shown to be an uncertain guide in determining the quality of oil of peppermint. (A. B. Stevens, *Proc. A. Ph. A.*, 1888, p. 97.)

Flückiger discovered that from 50 to 70 drops of peppermint oil, shaken with one drop of nitric acid, sp. gr. 1.2, turn faintly yellowish brown, and after an hour or two a most beautiful blue-violet or greenish-blue by transmitted light, or copper color by reflected light. Either a greater amount of acid or heating hastens the reaction. The color is very persistent. The presence of 5 per cent. of turpentine does not interfere with the reaction. (*P. J.*, Feb., 1871.)

Since menthol has been prepared largely from American peppermint oil, much of the latter has been put upon the market deprived of its menthol. To detect this fraud, Fritzsche Brothers recommend that a test tube partially filled with the oil and corked should be placed in a freezing mixture of ice and salt for ten or fifteen minutes. At the end of that time, if the oil has not been tampered with, it will have become cloudy, thick, or of a jelly-like consistence If then four or five small crystals of menthol be added, and the tube be replaced in the freezing mixture, the oil will in a very short time form a solid mass of crystals. For another method of testing dementholized oil, see a paper by E. C. Federer, *Ph. Era*, 1887, 36; also 1887, 97.

Power and Kleber first proposed (*Ph. Rund.*, 1894, 157) to estimate the menthol in oil of peppermint by acetylizing a sample and saponifying an exactly weighed portion of the acetylized oil after washing, drying, and filtering the same. Kleber (*A. J. P.*, 1897, 192) proposed to take instead a weighed quantity of the oil, acetylize it, and then saponify the product after washing and neutralizing it. In *Schimmel & Co.'s Report* for October, 1897, Kleber criticizes Kebler's modification, and claims greater accuracy for the original method. Of course, this determination gives the total menthol; a determination of the combined menthol is had by titrating with alcoholic alkali.

Peppermint oil has been variously mixed and adulterated with the following substances: alcohol, oil of turpentine, oil of copaiba, oil of erigeron (from the erigeron plant growing with the peppermint plant, and being collected with it for distillation), oil of eucalyptus, oil of pennyroyal, and others. Most of these are detectable by the official tests, or when present lower the assay strength, or are readily recognized by the odor or taste, which they communicate to the oil. For further details concerning some of these adulterants and their detection, see *U. S. D.*, 19th ed., p. 854, 855.

Chinese Oil of Peppermint has not found its way to any extent into commerce, yet it has at times attracted much attention. According to John Mackey, some of it has reached London in cylindrical tin canisters, and it is to be obtained in San Francisco. Some specimens resemble the ordinary oil, but become solid in cold weather; others remain liquid and show no tendency to deposit a camphor, while others are solid crystalline masses at all temperatures. It seems probable that the original Chinese oil contains a great excess of menthol, and constitutes the variety first spoken of, and that the solid and liquid oils are prepared by separating it into its two constituents. The solid oil Flückiger states not to differ from American menthol. (See *P. J.*, v, 366, 825.)

Uses.—Oil of peppermint possesses the physiological properties and therapeutic virtues of menthol, and may be used for practically all those conditions in which menthol is of service. It is generally preferred for internal use because of its more pleasant taste. It is an excellent carminative and gastric stimulant, and is widely employed in *flatulence*, *nausea*, and *gastralgia*. It adds to a stimulating effect upon the alimentary canal an antiseptic and local anesthetic influence. As a local application for *coryza* it may be used in strengths of from five to ten minims to an ounce of liquid petrolatum or olive oil. Incorporated into a lozenge it offers a pleasant and efficient antiseptic and anesthetic in *pharyngitis*. Internally it may be given either rubbed up with sugar and then dissolved in water, or more commonly in the form of the spirit. It is extremely popular as a flavoring agent.

Dose, one to five minims (0.06–0.3 mil).

OLEUM MENTHÆ VIRIDIS. U. S., Br.

OIL OF SPEARMINT Ol. Menth. Vir. [Spearmint Oil]

(ō'lē-ŭm mĕn'thæ vīr'ĭ-dīs)

"A volatile oil distilled from the flowering plant of *Mentha spicata* Linné (*Mentha viridis* Linné) (Fam. *Labiatæ*), and yielding not less than 43 per cent., by volume, of carvone [$C_{10}H_{14}O = 150.11$]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Spearmint is the oil distilled from fresh flowering spearmint, Mentha viridis, *Linn.*, or mentha crispa, *Roth.*" *Br.*

Huile volatile (Essence) de Menthe verte, *Fr.;* Römischminzöl, Krauseminzöl, *G.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country, the whole plant being used. It is pale yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany color. It is officially described as "a colorless yellow or greenish-yellow liquid, having the characteristic odor and taste of spearmint.

It is soluble in 1 volume of 80 per cent. alcohol, forming a clear solution; on further dilution, it usually becomes cloudy. Specific gravity: 0.917 to 0.934 at 25° C. (77° F.). The optical rotation varies between –38° and –55° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21).

"**Assay.**—Proceed as directed under *Oleum Cari*, using 10 mils of Oil of Spearmint." *U. S.*

"Colorless, pale yellow, or greenish-yellow, becoming darker on keeping. Odor and taste those of spearmint herb. Specific gravity 0.925 to 0.940; *optical rotation* –30° to –50°. Soluble in 3 parts of *alcohol* (90 per cent.). Forms a clear solution with 1 part of a mixture of equal volumes of *alcohol* (90 per cent.) and *alcohol* (70 per cent.), the solution becoming turbid on further dilution." *Br.*

Oil of spearmint contains a terpene, l. limonene, $C_{10}H_{16}$, and *l. carvone*, $C_{10}H_{14}O$. Baeyer found the *l. carvone* in both German and American oils to the amount of from 35 to 56 per cent. (*A. Pharm.*, cexii, 283.) Schimmel & Co., in an investigation of Russian oil, found from 5 to 10 per cent. of carvone only, but 50 to 60 per cent. of linalool, together with some cineol and l. limonene. (*Schim. Rep.*, April, 1898.) It is used chiefly for its flavor, especially in chewing gum.

The peculiar odor of spearmint oil has not yet been definitely associated with any of its constituents. It was for a time thought to be due to an acetic derivative of dihydrocuminyl, but this has recently been denied so far as the oil of American origin is concerned.

Dose, one to six minims (0.06–0.4 mil).

OLEUM MORRHUÆ. U. S., Br.

COD LIVER OIL. Ol. Morrh. [Oleum Jecoris Aselli]

(ō'lę-ŭm mör'rhú-æ)

"A fixed oil obtained from the fresh livers of *Gadus morrhua* Linné and of other species of *Gadus* (Fam. *Gadidæ*). Preserve it in a cool place, in well-closed containers, which have been thoroughly dried before filling." *U. S.* "Cod-liver Oil is the oil expressed from the fresh liver of the cod, Gadus morrhua, *Linn.*, at a temperature not exceeding 85° C. (185° F.), and from which solid fat has been separated by filtration at about –5° C. (23° F.)." *Br.*

Oleum Hepatis Morrhuæ; Cod Oil; Huile de Foie de Morue, *Fr. Cod.;* Huile de Morue, *Fr.;* Oleum Jecoris Aselli, *P. G.;* Leberthran, Stockfischleberthran, Dorschleberthran, Kabliauleberthran, *G.;* Olio di fegato di merluzzo, *It.;* Aceite de higado de bacalao, *Sp.*

Gadus morrhua Linn.; *Morrhua vulgaris* Storer.—The *common cod* is between two and three feet long, with brown or yellowish spots on the back. The body is moderately elongated and somewhat compressed, and covered with soft, rather small scales, being quite conspicuous also on the head. Of the fins, which are soft, there are three on the back (dorsal), two anal, and a distinct caudal, and the fin (ventral) under the throat is narrow and pointed. The jaws are furnished with pointed irregular teeth, in several ranks. The gills are large, with seven rays. This species of cod inhabits the cold waters of the Northern Atlantic, and is especially abundant on the Banks of Newfoundland, where it finds food adapted to its wants.

Besides the common cod, several other species of *Gadus*, frequenting the seas of Northern Europe and America, contribute to furnish the cod liver oil of commerce. Among these De Jongh mentions *Gadus callarias*, or *dorsch* (*Morrhua americana* of Storer), *G. molva*, or *ling*, *G. carbonarius*, or *coal fish*, and *G. pollachius*, or *pollack*, as affording the oil on the coast of Norway, where from 17,000,000 to 35,000,000 of codfish are annually taken. For an account of the mode of fishing for cod and of preparing the oil practised in Norway and Denmark, see *P. J.*, April, 1877, p. 810; *N. R.*, March, 1878; *Ph. Ztg.*, 1900, 261; *Ph. Era*, 1904, 111; *C. D.*, 1904, 21.

On the American coast, in addition to the pollack above mentioned, it is obtained also from the *hake* (*G. merluccius*) and the *haddock* (*G. æglefinus*). It is produced on our coast north of Boston. The oil is also largely produced in Newfoundland, Great Britain, Norway, and to some extent in Iceland.

Preparation.—Fishermen were for a long time in the habit of collecting this oil, which was largely consumed in the arts, particularly in the preparation of leather. Upon the coasts of Newfoundland, Nova Scotia, and New England, the boats which fish near the shore, being small, soon obtain a load, and, running in to land, deliver their cargoes to persons whose business it is to cleanse and salt the fish. The oil was formerly prepared in the huts of the fishermen, but is now prepared more largely at establishments to which the livers are conveyed in quantities. These are put into a boiler with water, and heated until they are broken up into a pultaceous mass, which is thrown upon a strainer covering the top of a cask or tub. The liquid portion passes, and upon standing separates into two parts, the oil rising to the surface of the water. The oil is then drawn off, and, having been again strained, is prepared for the market. Another and improved method, which has come into use since the extensive employment of the oil as a medicine, is to heat the livers in a wooden butt by means of low pressure steam. The pultaceous mass resulting is drained as before mentioned—the livers themselves containing, besides oil, a considerable portion of aqueous fluid, which passes off with it in the form of emulsion and separates on standing. In the case of the finest American varieties, the oil, which is made only in the winter months, is drawn off by taps from the bottom of the cooking butt, and then put into a cooling house to freeze. The solid frozen mass is put into canvas bags, and submitted, while at a low temperature, to severe pressure, whereby the pure liquid oil is forced out, leav-

ing a whitish, tallow-like mass, composed of stearin and liver débris. This residue is sold to the soap makers, and the oil bottled without further process. The oil thus variously procured was called *shore oil,* and is the purest kind. The manufacture of refined oil by improved processes is developing rapidly in Newfoundland. (See *West. Drug.,* 1897, 13.)

Formerly the crews of the larger boats, which fish upon banks far from land, cleansed the fish on board, and, throwing the offal into the sea, put the livers into barrels or other receptacles, where they underwent a gradual decomposition, the oil rising to the surface as it escaped from the disintegrating tissue. From this was obtained the so-called "Straits oil" and "banks oil." The method is, however, no longer in vogue and these forms of the oil are unknown in commerce. For further details see *U. S. D.,* 19th edition, p. 857, and *A. J. P.,* xxiii, 97; xxvi, 1. Large quantities of Norwegian cod liver oil are sold in the United States; the method of extraction depending on the action of steam does not differ greatly from that used in America. Another oil is made by the cold process and B. Rauitz, *Ph. Ztg.,* 1900, 261, furnishes the following account: The fresh livers, separated from the gall-bladder, are placed in a wooden tub, 5 feet in height by 7 feet in diameter, until the tub is nearly full, which is then left exposed to the action of the sun, shining day and night in these high latitudes. After about three weeks the extraction is completed, and, owing to the favorable atmospheric conditions and the evident absence of germs in this far polar region, not the slightest evidence of decomposition manifests itself during this process. The oil runs off pure and simply has the odor characteristic of cod liver oil, and while the "steam cod liver oil" requires refining, that obtained by the "cold process" described is ready for the market as run off from the tubs. This explains why in more southerly latitudes it is impossible to prepare a satisfactory cod liver oil; the cold process is not available, while the steam process does not yield a desirable oil.

The oil is sometimes procured by expression. Donovan recommends the following plan, which affords a very fine oil. The livers, perfectly sound and fresh, are to be placed in a clean iron pot over a slow fire, and stirred until they assume the condition of a pulp, care being taken that the mass be not heated beyond 88.9° C. (192° F.). When this temperature is attained, the pot is to be removed from the fire, and its contents introduced into a canvas bag, through which water and oil will flow into a vessel beneath. After twenty-four hours, the oil is to be decanted and filtered through paper. In this state it is pale yellow, with little odor, and a bland not disagreeable taste.

Properties.—Cod liver oil prepared by the putrefactive method had a brown color and a strong offensive odor and flavor. It contained a large proportion of free fatty acids. The color of the modern oil is from the slightest tint of transparent yellow to a fine golden yellow. It is of a rather thin consistence, and has a characteristic odor and taste, by which it may be distinguished from other oils. We regard the sensible properties as the most certain tests of the genuineness of the oil. They are much less distinguishable in the pale than in the dark brown varieties, but we have met with no specimen which did not possess them in some degree. In the purest they are scarcely repulsive, in the dark brown they are very much so. When a decided odor of ordinary fish oil is perceived, the genuineness may always be suspected. It is quite distinct from that peculiar to the cod liver oil. The pale yellow oil is now exclusively used for medicinal purposes. The sp. gr. at 22.4° C. 72° F.), as ascertained by Procter, varied from 0.915 to 0.9195—the first being that of the *hake* oil, the second that of the *haddock,* while the sp. gr. of the purest oil from the common cod was 0.917. De Jongh found the sp. gr. at 17.2° C. (63° F.) of the pale 0.923, of the light brown 0.924, of the dark brown 0.929. The oil from the cod does not congeal at –10° C. (14° F.), though that of *G. carbonarius* and that of the livers of different species of *Raja* let fall at that temperature a solid fatty matter, supposed to be palmitin. Alcohol dissolves from 2.5 to 6 per cent., water from 0.637 to 1.28 per cent., of different varieties, the pale yielding least to these solvents. (*J. P. C.,* Jan., 1854, p. 39.) The official description is as follows: "Cod Liver Oil is a pale yellow, thin, oily liquid, having a peculiar, slightly fishy, but not rancid odor, and a fishy taste. It is slightly soluble in alcohol; soluble in ether, chloroform, carbon disulphide, or ethyl acetate. Specific gravity: 0.918 to 0.922 at 25° C. (77° F.). A solution of 1 drop of the Oil in 1 mil of chloroform when shaken with 1 drop of sulphuric acid acquires a violet-red tint, gradually changing to reddish-brown. Allow 2 or 3 drops of fuming nitric acid (specific gravity about 1.44) to flow alongside of 10 or 15 drops of the Oil contained in a watch glass; a reddish or purplish color is produced at the zone of contact. On stirring the mixture with a glass rod, this color becomes bright rose-red (distinction from *seal oil,* which shows no change in color, and from *other fish oils,* which become blue). Cod Liver Oil is only slightly acid to litmus paper which has been previously moistened with alcohol (*free fatty acids*). Saponification value: not less than 180 nor more than 190 (see Part III, Test No. 9). Iodine value: not less than 140 nor more than 180 (see Part III, Test No. 8)." *U. S.*

"Pale yellow. Slight, fishlike, but not rancid odor; taste bland, fishlike. Specific gravity 0.920 to 0.930; *saponification value* 179 to 192; *iodine value* 155 to 173; *acid value* not more than 2.5; *refractive index* at 40° C. (104° F.) 1.4704 to 1.4745; *unsaponifiable matter* not more than 1.5 per cent. When exposed for three hours to a temperature of 0° C. (32° F.), no solid fat separates." *Br.*

The chemical composition of the glycerides in

cod liver oil is very complicated. Palmitic and stearic acids are present. But the so-called "stearin" separating from cod liver oil on cooling contains some unknown unsaturated compounds, as the cod liver stearin has a very high iodine value (113.4, Heyerdahl; 94, Lewkowitsch). The glycerides of the lower fatty acids, such as acetic, butyric, valeric, and capric acids, stated by various authors to occur in cod liver oil, are according to Salkowski and Steenbuch, secondary products due to the putrefaction of the livers. The researches of Heyerdahl (*Cod Liver Oil and Chemistry*, P. Möller, London, 1895) give as present in the mixed fatty acids about 4 per cent. of palmitic acid, 20 per cent. of *jecoleic acid*, $C_{18}H_{36}O_2$, and 20 per cent. of *therapic acid*, $C_{17}H_{26}O_2$, *morrhuic acid*, $C_9H_{13}O_3N$, and *asellic acid*, $C_{17}H_{32}O_2$, have also been reported. The former is a nitrogenous compound and is supposed to be identical with a basic substance named *gaduine* which had been reported. Heyerdahl states that in the fresh state cod liver oil contains no hydroxy-acids.

A characteristic constituent of cod liver oil is *cholesterol*, which can be isolated by saponifying the oil and exhausting the soap with ether. The quantity of cholesterol, according to Allen and Thomson, is from 0.46 to 1.32 per cent. By reaction with ammonia in distillation the oil yields a volatile alkaloid, *trimethylamine*, C_3H_9N, which has a strong pungent odor, recalling that of herring pickle, of which the same alkaloid is an ingredient. No other official fatty oil yields a similar product. (See *A. J. P.*, xxiv, 343.) Gautier has obtained from cod liver oil the leucomaines *butylamine, iso-amylamine, hexylamine*, and *dihydrolutidine*, and two fixed bases, *aselline*, $C_{25}H_{32}N_4$, and *morrhuine*, $C_{19}H_{27}N_3$. Aselline was found by its discoverer to be relatively feeble physiologically; morrhuine, of which about 2 milligrammes are believed to exist in a tablespoonful of ordinary cod liver oil, is affirmed to have the properties of exciting the appetite and acting as a powerful diuretic and diaphoretic. Besides these bases, an acid containing nitrogen has been found. This acid, *morrhuic acid*, $C_9H_{13}NO_3$, is probably identical with De Jongh's *gaduine*. Some have been disposed to ascribe the virtues of cod liver oil to its iodine and bromine, but these are in too small proportion for any effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap, and to carbonize this, before it will give evidence of iodine. The proportion never exceeds 0.05 per cent., or 1 part in 2000, and it is by no means certain that iodine is always, if ever, present in pure oil. The proportion of iodine present has been investigated by E. C. Stanford (*P. J.* [3], xiv, 353), who found it to be extremely minute, ranging from 0.00138 to 0.00433 per cent., with an average of 0.00322 per cent. The oil is capable of dissolving a larger proportion of iodine, and, if any specimen contain more than 0.05 per cent., there is reason to suspect that iodine has been added. Cod liver oil becomes rancid so easily that it contains varying amounts of free fatty acids, frequently showing their presence, even when freshly rendered. Medicinal oils, however, should not show more than from 0.3 to 0.7 per cent. of free acid, calculated as oleic acid.

The so-called active principles of cod liver oil which are found in the market under various names indicative of their origin are usually made by alcoholic extraction of the oil or of the livers themselves. They consist almost entirely of crude fatty acids, no iodine, bromine or phosphorus is detectable, the bases which are sometimes present are in very minute amount, and are probably of the ptomaine type, derived from partly decomposed products. These so-called alcoholic extracts or active principles are themselves scarcely soluble in diluted alcoholic menstrua, such as are used in preparing the so-called "tasteless" preparations of cod liver oil, so that such preparations can possess little or no activity due to cod liver products.

Tests of Purity.—In consequence of the great demand for this oil, it has not infrequently been adulterated with other fixed oils, and occasionally others have been fraudulently substituted for it. The importance, therefore, of ascertaining some mode of testing its purity and genuineness is obvious.

There is reason to believe that all the oils from the livers of the *Gadidæ* have analogous properties. They have been indiscriminately used, and upon the results of their employment is based, in part, the present reputation of the medicine. They may, therefore, be considered as in fact one oil, so far as their medicinal use is concerned. Unfortunately, chemistry has yet discovered no perfectly reliable test. The furthest it has gone is to point out certain reactions, which may be considered as evidences of the presence of biliary principles in the oil, thus indicating its hepatic origin. Among these probably the most characteristic is that of Hager and Salkowski, in which a drop of sulphuric acid, added to fresh cod liver oil, on a porcelain plate, causes a centrifugal movement in the oil, and gives rise to a fine violet color, soon passing into a yellowish or brownish-red. Sometimes, instead of assuming the violet hue, the color immediately becomes a clear red or a dark brownish-red. This is said to be especially the case with those specimens of the oil which have been prepared by boiling the livers with water. Shark liver oil responds in like manner to the test of sulphuric acid, but is said to have the sp. gr. 0.866, which is much lower than that of any variety of the genuine oil. Rauitz (*Ph. Ztg.*, 1900, 261) states that Norwegian oil prepared by the cold process is often adulterated with the oil from a species of shark, *Scymnus vulgaris*. According to Kremel, fuming nitric acid causes instantly, when agitated with cod liver oil, a pinkish or rose-red color, which soon becomes

brown, while no such effect is produced on other animal or vegetable oils. According to Winckler, the oil should afford the odor of herring pickle when heated with potassium hydroxide, lime, and ammonium chloride. But the most reliable tests are the sensible properties of odor and taste. If there be none of the peculiar shoe leather odor and taste, or if a strong lamp oil odor be perceptible, the oil may be suspected. Little of importance can be inferred from the color.

Uses.—Dr. Owen T. Williams (*P. J.*, 1912, p. 806), in discussing the subject of cod liver oil from the pharmacological and biochemic standpoint, states that the idea that the value of cod liver oil is due to the presence of infinitesimal amounts of constituents, such as sulphur, iodine, phosphorus, etc., is not true, but that its peculiar effectiveness in *tuberculosis* is intimately associated with its food value and is due to the fat itself, which being free from phosphates and consisting almost entirely of unsaturated fatty compounds is a different type of fat from those usually administered or found in foods of the oils on the market. He states that those have the greatest value which have been prepared under the most favorable conditions to prevent oxidation.

The questions of the way in which cod liver oil exercises its beneficent influence in morbid conditions, and to which of its numerous ingredients it owes its therapeutic value, are still matters of difference of opinion. Formerly many attributed its actions to the traces of iodine, phosphorus, or organic bases it contained. This view has, however, been generally abandoned; the extracts containing these principles separated from the oil have not yielded the same results. The therapeutic virtues, therefore, apparently reside in some of the constituents of the oil itself. Whether or not it acts simply as a foodstuff or whether it has some direct influence on the bodily metabolism, is open to dispute. It seems pretty well established that not only is cod liver oil absorbed from the intestinal tract better than any other fats, but that it actually increases the utilization of other forms of fatty foods. An interesting observation has been made by Osborne and Mendel that young rats who have been fed on a diet containing no form of fat but lard until their growth has ceased, will immediately recommence growing when cod liver oil is substituted for the lard. Williams (*B. M. J.*, 1912, ii, p. 700) believes that the unsaturated fatty acids have a direct inhibiting effect on the growth of the tubercle bacilli which may in part explain its action in tuberculosis.

Cod liver oil is used in all forms of *malnutrition*, especially, however, in various forms of *tuberculosis*. The old idea that it had a specific influence in this infection is probably incorrect, but in the reaction against its use the pendulum has swung too far and it is ofttimes neglected or even condemned in cases in which it might be well employed. It is often of service in those types of *chronic rheumatism* or *gout* which are associated with malnutrition, and has been highly lauded in *rickets* and other diseases of the bones. It is unique among the oils in that it is absorbable through the skin, at least by young infants, in sufficient quantity to have a perceptible influence upon nutrition.

Various measures have been recommended for overcoming the objectionable taste which is a great obstacle to the wider use of this remedy. None of these, however, are entirely successful. It is most frequently exhibited in the form of one of the numerous emulsions upon the market, of which that with malt extract is one of the best. It is sometimes given in flexible capsules, but these have the objection that they can only hold comparatively small doses. Dufourmantel (*J. P. C.*, June, 1864) prepared a jelly by dissolving half a drachm of ichthyocolla in as little hot water as possible, and then gradually mixing with it a fluidounce of the oil with four drops of the oil of anise, taking care that the temperature should not rise above 24° C. (75.2° F.).

Phosphorized cod liver oil may be made by dissolving one grain of phosphorus in four fluidounces of cod liver oil.

Glyconin Emulsion of Cod Liver Oil.—The formula proposed by Close, and at one time largely used by Andrews, Beard, and others, is as follows: Cod liver oil, 4 fluidounces; glyconin, 9 fluidrachms; aromatic spirit of ammonia, 1 fluidrachm; sherry wine, 2 fluidounces, diluted phosphoric acid, 4 fluidrachms, essence of bitter almond (made by dissolving 1 fluidrachm of the volatile oil in half a pint of alcohol) 2 fluidrachms. The cod liver oil is to be added *very slowly* to the glyconin with brisk stirring, and the other ingredients added in the order named. *Glyconin* or *Glyceritum Vitelli* is made by mixing 45 Gm. of fresh yolk of egg with 55 Gm. of glycerin.

The following is Carlo Pavesi's formula for deodorized cod liver oil. Cod liver oil, 1000 parts; ground roasted coffee, 50 parts; animal charcoal, 25 parts. Place the ingredients in a flask, which is to be well closed, and digest on a water bath during the space of one hour; then set it aside for three days, occasionally shaking the contents, and filter. This preparation has a peculiar coffee flavor, and is quite pleasant to take, the only objection being the liability to cultivate in the patient a distaste for using coffee as a beverage. (*N. R.*, Jan., 1876.)

The *olein* of cod liver oil has been recommended by Arthur Leared, when the oil itself disagrees with the stomach. He has found it to produce the same remedial effects, and to be borne much better. It may be given in the same dose. A *solution of quinine in the oil* may be made by heating the freshly precipitated alkaloid with the oil, in the proportion of two grains to a fluidounce, by means of a water bath, until the mixture becomes quite clear.

Dose, one to four fluidrachms (3.75–15 mils).

OLEUM MYRISTICÆ. U. S., Br.

OIL OF MYRISTICA Ol. Myrist. [Myristica Oil, Oil of Nutmeg]

(ō'lę-ŭm mȳ-rĭs'tĭ'cæ)

"A volatile oil distilled from the kernel of the ripe seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Nutmeg is the oil distilled from Nutmeg, and rectified." *Br.*

Volatile oil of Nutmeg; Oleum Myristicæ Ætherеum, Oleum Nucis Moschati, Oleum Nucistæ Ætherеum; Huile volatile (Essence) de Muscade, *Fr.;* Oleum Macidis, *P. G.;* Aetherisches Muskatöl, Aetherisches Muskatnussöl, *G.*

This oil is obtained from nutmegs after powdering them by distillation with water. A better method, according to J. Cloez, is to exhaust the powder with carbon disulphide or ether, distil off the solvent by means of a water bath, and expose the butter-like residue to a current of steam, the vapor being conveyed into a refrigerated receiver, where it condenses. (*J. P. C.,* Fév., 1864.) Schimmel & Co. (1899) state that oil of nutmeg is made from the light, worm-eaten nuts, of which large quantities are rejected in sorting the different qualities in Holland. The worm most strangely robs the nutmeg of its fat oil, while the essential oil remains in the nut in full. Oil of myristica is colorless or of a pale straw color, limpid, lighter than water, soluble in an equal volume of glacial acetic acid, in alcohol and ether, with a neutral reaction, a pungent spicy taste, and a strong odor of nutmeg. It is officially described in the United States Pharmacopœia (Ninth Revision) as "a colorless or pale yellow liquid, having the characteristic odor and taste of nutmeg. It is soluble in an equal volume of alcohol; also soluble in 3 volumes of 90 per cent. alcohol. Specific gravity: 0.859 to 0.924 at 25° C. (77° F.). The optical rotation varies from +12° to +30° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21). Evaporate 3 Gm. of the Oil on a water bath; not more than 0.06 Gm. of residue remains." *U. S.*

"Colorless or pale yellow. Odor and taste those of Nutmeg. Specific gravity 0.870 to 0.925; *optical rotation* +13° to +30°; *refractive index* at 25° C. (77° F.) 1.474 to 1.484. Soluble in 3 parts of *alcohol* (90 per cent.). Leaves not more than 5 per cent. of residue when evaporated on a water-bath." *Br.*

The mixture of volatile and fixed oils obtained by powerfully expressing nutmegs between heated plates may be separated by agitation with water. Upon standing, the latter deposits a crystalline solid, which was called by Playfair *myristin.* From its solution in alcohol he obtained it in extremely light crystalline scales, which, after repeated crystallization, had still the odor of nutmeg, were fusible at 31° C. (87.8° F.), soluble in the ordinary menstrua of substances of the same class, and, as just said, insoluble in water. By glacial acetic acid it was first colored red. (*P. J.,* March, 1874, 714.) It was identified as the glyceride of *myristic acid,* $C_{14}H_{28}O_2$, and had, therefore, the formula $C_3H_5(C_{14}H_{27}O_2)_3$. Besides the myristin or solid fat, there is present about an equal amount of a liquid fat containing free acid. The essential oil consists chiefly of pinene with probably some dipentene, also *myristicol,* $C_{10}H_{16}O$, and *myristicin,* $C_{11}H_{12}O_3$, linalool, borneol, terpineol, geraniol, eugenol, and a number of organic acids. Semmler (*Ber. d. Chem. Ges.,* 1890, 1803) examined an oil of myristica of sp. gr. 0.8611 which contained only terpenes; these boiled at about 50° C. (122° F.) under a pressure of 8 mm.

Uses.—The oil of nutmeg unites to the common properties of the aromatics considerable narcotic power. It causes in the lower animals dilatation of the pupils, unsteadiness of the gait followed by sleepiness, with slow respiration, and, if the dose be large enough, loss of reflexes. According to Dale (*Proc. Royal Soc. Med.,* Feb., 1909) doses large enough to produce narcosis in the cats are invariably fatal through fatty degeneration of the liver. A number of fatal cases of nutmeg poisoning have been reported in human beings. The symptoms have been the same as those which are observed in the lower animals. The toxic ingredient is myristicin.

The oil of nutmeg is used to correct the taste of various drugs and as a local stimulant to the gastro-intestinal tract.

Dose, one to five minims (0.06–0.3 mil).

Off. Prep.—Spiritus Myristicæ, *Br.;* Elixir Glycyrrhizæ Aromaticum, *N. F.;* Elixir Pepsini et Rennini Compositum, *N. F.;* Mistura Oleo-Balsamica, *N. F.*

OLEUM OLIVÆ. U. S., Br.

OLIVE OIL Ol. Oliv.

(ō'lę-ŭm ǫ-lī'væ)

"A fixed oil obtained from the ripe fruit of *Olea europæa* Linné (Fam. *Oleaceæ*). Preserve it in well-closed containers, in a cool place." *U. S.* "Olive Oil is the oil expressed from the ripe fruit of Olea europæa, *Linn.,* and refined." *Br.*

Sweet Oil; Huile d'Olive, *Fr. Cod.;* Oleum Olivarum, *P. G.;* Olivenöl, *G.;* Olio di olive, *It.;* Aceite de olivas, *Sp.*

Olea europæa L. is one of the leading fruit trees of the world. It is usually from fifteen to twenty-five feet in height, though sometimes much larger, especially in Greece and the Levant. It has a solid, erect, unequal stem, with numer-

ous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dark green color on their upper surface, whitish and almost silvery beneath. The flowers are small, yellowish-white, and disposed in opposite axillary clusters, about half as long as the leaves, and accompanied with small, obtuse, hoary bracts. The fruit, or olive, is a smooth, oblong or oval drupe, greenish at first, but of a deep violet color when ripe, with a fleshy pericarp, and a very hard nut of a similar shape. Clusters of not less than thirty flowers yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the south of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are forty varieties, distinguished by the form of the leaves and the shape, color, and size of the fruit. The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the south of France, and the *latifolia* in Spain. The latter bears much larger fruit than the former, but the oil is less esteemed. The olive is largely cultivated in the north of Africa, especially in the vicinity of Tunis, and considerable quantities of the oil are exported from that city. (*P. J.*, Sept., 1873, 204.) The tree has been introduced into South Australia, and the oil will probably become of commercial importance there.

Olives are cultivated especially in Spain in the district of Cadiz. Two classes are produced, the one known as the "Queen olive," a large olive, which is mostly exported to the United States; the other the Manzanillo, or small olive, which is chiefly consumed in Spain, South America and Cuba. The Spanish production for 1916 amounted to 1,146,599 metric tons of olives and the oil to 207,115 tons. The olive is largely cultivated in California, where it grows luxuriantly. The production of olive oil in the United States in 1916 was 1,336,674 lbs. produced in 22 establishments. The importation of edible olive oil amounted to 7,382,353 gallons.

There are many varieties of the olive grown in California. J. L. Howland, of Pomona, reports the following percentage of oil yielded by each variety as cultivated in California as the result of two years' test; Pendulina, 21; Rubra, 18.5; Oblonga, 18; Mission, 17.9; Uvaria, 17.5; Nevadillo Blanco, 16.5; Columella, 16.5; Precox, 14; Picholine, 10; Manzanillo, 8.5. For further information concerning the subject the reader is referred to the various Proceedings of the California State Convention of Olive Growers.

Pickled olives, made by soaking green olives first in dilute solution of sodium hydroxide and then in salt water, are largely used as an article of food; the ordinary green olive of commerce has been picked before ripening. The ripe olive, which, in the United States, is chiefly obtained from California, is dark-purple, often almost black, very different in taste from the ordinary unripe pickled fruit, and is said to contain about 50 per cent. of olive oil, so that it affords an excellent method of administering fat.

The leaves and bark of the olive tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. Attention has been called, in France, to a hydro-alcoholic extract of the leaves, as having considerable febrifuge powers. In the quantity of from ten to twenty grains daily, in divided doses, it has been found useful in preventing the hectic paroxysms. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resin, a little benzoic acid, and a peculiar principle analogous to gum, which has been named *olivile*. But the fruit is by far the most useful product. In the unripe state it is hard and insupportably acrid, but when macerated in water or an alkaline solution, and afterwards introduced into a solution of common salt it loses these properties, and becomes a pleasant and highly esteemed article of diet. Mannite has been found in all parts of the tree while in vital activity, as in the green leaves and unripe fruit, but cannot be detected in the yellow fallen leaves or in the perfectly ripe fruit. (*A. J. P.*, 1866, p. 179.) The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in Southern Europe. In the unripe olive a peculiar green substance, together with mannite, has been found by S. de Lutz, both of which disappear as the fruit ripens, being probably converted into oil, which now takes their place. (*J. P. C.*, June and Dec., 1862.) The olives ripen from November to March, and the oil is obtained by first bruising them in a mill and then submitting them to pressure. The product varies much, according to the state of the fruit and the circumstances of the process. The best, called *virgin oil*, is obtained from the fruit picked before perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes and in the manufacture of the finest soaps is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case the pulp is thrown into boiling water, and the oil removed as it rises. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, etc., is afforded by fruit which has been thrown into heaps, and allowed to ferment for several days, or by the marc left after the expression of the finer kinds of oil, broken up, allowed to ferment, and again introduced into the press. The

remarks made under the head of *Oleum Myristicæ* in relation to the extraction of the fixed oils by means of solvents are applicable also to olive oil.

Properties.—The pure oil is an unctuous liquid, or "a pale yellow or light greenish-yellow, oily liquid, having a slight, peculiar odor and taste, with a faintly acrid after-taste. It is slightly soluble in alcohol, but miscible with ether, chloroform, or carbon disulphide. Specific gravity: 0.910 to 0.915 at 25° C. (77° F.). When cooled to from 10° to 8° C. (50°–46.4° F.), the Oil becomes somewhat cloudy from the separation of crystalline particles, and at 0° C. (32° F.) it usually forms a whitish, granular mass. Mix 5 mils of the Oil in a test tube with 5 mils of a mixture of equal volumes of amyl alcohol and carbon disulphide, which contains 1 per cent. of sulphur in solution, and immerse the test tube to one-third its depth in boiling, saturated aqueous salt solution; no reddish color develops in fifteen minutes (*cottonseed oil*). Mix 2 mils of the Oil with 1 mil of hydrochloric acid containing 1 per cent. of sugar, shake the mixture for half a minute and allow it to stand for five minutes; on now adding 3 mils of distilled water to the mixture and again shaking it, the acid layer shows no pink color (*sesame oil*). Saponification value: not less than 190 nor more than 195 (see Part III, Test No. 9). Iodine value: not less than 79 nor more than 90 (see Part III, Test No. 8)." *U. S.*

"Pale yellow or greenish yellow. Faint but not rancid odor; taste bland. Frequently assumes a pasty consistence when maintained for some time at a temperature of 10° C. (50° F.), and at a lower temperature may become a soft granular mass. Specific gravity 0.915 to 0.918; *saponification value* 188 to 197; *iodine value* 79 to 87; *acid value* not more than 6.0; *refractive index* at 40° C. (104° F.) 1.4605 to 1.4635. A mixture of 2 millilitres of the Oil with 1 millilitre of *amylic alcohol* and 1 millilitre of a solution (1 in 100) of *precipitated sulphur* in *carbon disulphide*, placed in a test-tube immersed in boiling *water*, does not assume a red color within thirty minutes (absence of cottonseed oil). When a mixture of 2 millilitres of the Oil and 1 millilitre of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute, and allowed to stand for five minutes, the acid layer does not become pink (absence of sesame oil). When 1 millilitre of the Oil and 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* are boiled for twenty minutes in a flask provided with a reflux condenser, set aside for twenty-four hours at a temperature not exceeding 15.5° C. (60° F.), and afterwards heated on a water-bath for three minutes, the solution does not deposit crystals on standing for twenty-four hours further (absence of arachis oil)." *Br.*

The concrete portion, about 28 per cent. of the oil, which separates at a freezing temperature, consists chiefly of the glyceride of *palmitic acid*, $C_{16}H_{32}O_2$, together with a smaller amount of glyceride of *arachidic acid*, $C_{20}H_{40}O_2$ (stearic acid is stated by Hehner and Mitchell to be absent entirely); the liquid portion is essentially olein, $C_3H_5(O.C_{18}H_{33}O)_3$, with a small amount (seven parts for ninety-three of olein) of the glyceride of the less saturated linolic acid. According to Braconnot, the oil contains 72 per cent. of olein and 28 of palmitin. A small quantity of phytosterin has also been found in the oil. Olive oil is solidified by nitrous acid and mercuric nitrate, and converted into a peculiar fatty substance, called *elaidin*. The olein of all oils which have not the drying property undergoes the same change when acted on by nitrous acid.

The greenish color is owing to the presence of a trace of chlorophyll, and a trace of cholesterin is also extracted by repeated agitation with glacial acetic acid.

For discussion of the spectra of olive oil, see *P. J.*, 3d series, vii, 22, 110.

Olive oil, when exposed to the air, is prone to become rancid, acquiring a disagreeable odor, a sharp taste, and a thicker consistence; it also loses its color, and the change is promoted by heating it.

It is frequently adulterated with the cheaper fixed oils, especially with cottonseed oil, arachis oil, sesame oil and poppy seed oil; the adulteration may sometimes be detected by reducing the temperature to the freezing point. As other oils are less readily congealed than is the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by Poutet, founded on the property possessed by mercuric nitrate of solidifying the oil of olives, without a similar influence upon other oils. Six parts of mercury are dissolved at a low temperature in seven and a half parts of nitric acid of the sp. gr. 1.35, and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it will be converted after some hours into a yellow solid mass; if it contains a minute proportion, even so small as a twentieth, of poppy or cottonseed oil, the resulting mass will be much less firm, and a tenth will prevent a greater degree of consistence than oils usually acquire when they concrete by cold. Lewkowitsch (*Chemical Analysis of Oils, Fats, and Waxes*, 2d ed., 1898, 462) says that the color reactions proposed by various authors are altogether unreliable and yield no definite results, with the exception of the color test (Baudoin's test, see *Oleum Sesami*) for sesame oil and perhaps Bechi's and Milliau's or Halphen's for cottonseed oil. For a method of detecting the *oil of arachis* (*ground nut oil*) in olive oil, see *J. P. C.*, Jan., 1872, 48. Bulletin 77 (1905), of the Bureau of Chemistry, United States Department of Agriculture, showed that most of the spurious and adulterated olive oil in the United States was of domestic origin and that the oil as imported in original packages was mostly genuine. This has been verified by numerous other investigators during recent years. Since the passage of the Food and Drugs

Act in 1906 it is rare to find a labeled container of olive oil adulterated, although much that is sold in bulk is still found to be spurious. In several states it has been judicially decided that the synonyms "sweet oil" and "salad oil" when unqualified mean olive oil. A low grade of olive oil used for soap making and other technical purposes is imported at a less rate duty than is collected on edible olive oil. The frequent use of such low grade oil for table purposes by those who are not particular about quality and flavor led to the requirement on the Part of the U. S. Treasury Department that such "technical oil" must be denatured for admission. There are three alternative and optional methods of denaturing. They consist in adding to the oil a small portion of oleoresin of capsicum, of oil of rosemary or of kerosene. Arachis oil, which is produced in large quantities in Marseilles, has been found in numerous samples of imported olive oil. According to Tambon, the present-day adulterations do not consist in the addition of a single cheaper oil, but of ingeniously prepared mixtures of different oils in such proportions to each other that on analysis it becomes difficult or impossible to distinguish the adulterated from the genuine oil by the chemical and physical constants accepted for the latter. The chief adulterants are benne, peanut and cottonseed oils. Of these, benne is easily recognized; for peanut oil there is as yet no reliable color reaction, and while Bechi's reaction may, under certain conditions, answer well for the detection of cottonseed oil, this, under others, has also proven unreliable. (*Ph. Ztg.*, 1904, 104.) According to Kreis and Grob (*S. W. P.*, 1901, 88) Billier's test is very sensitive. It is carried out by shaking the suspected oil with a solution of resorcinol in benzene and afterwards with nitric acid. Olive oil under these circumstances remains unchanged in color, cottonseed and nut oil become red violet and maw seed oil is turned brown red. Bechi's test for ascertaining the admixture of cottonseed oil with olive oil has received the approval of the Commission of Florence after most exhaustive experiments, and is as follows: One grain (0.065 Gm.) of silver nitrate is dissolved in fifteen minims (0.9 mil) of water, and six and a half fluidounces (195 mils) of alcohol are added. Two fluidounces (or 60 mils) of ether may be added to render the solution more easily miscible with the oil, but it is not absolutely necessary. A solution of eighty-five parts of amyl alcohol and fifteen parts of rape seed oil is prepared. These reagents should not be kept on hand any length of time. To ten mils of the oil to be examined one mil of the solution of silver nitrate is added, and then from eight to ten mils of the amyl alcohol reagent; the mixture is agitated strongly, and heated on a water bath for five or ten minutes. In the case of pure oils the color is unaltered by the addition of the reagents; if cottonseed oil be present, a brownish color or turbidity, varying from a light brown to a deep maroon or black (according to the extent of the adulteration), will be produced. (*A. J. P.*, 1887.) See also the official silver nitrate test. Milliau's test is a modification of the foregoing. If the fatty acids instead of the oil itself are treated with the same reagents, the same reduction of the silver salts occurs and the same brown color as in the Bechi test. Halphen's test with a mixture of amyl alcohol and carbon disulphide containing about 1 per cent. of sulphur in solution is now regarded as the most distinctive for cottonseed oil. For details see the official test.

Uses.—Olive oil is nutritious and mildly laxative and is often used in milder cases of chronic *constipation*, especially when associated with malnutrition. In the form of enema it is often a useful remedy in *fecal impaction*. It has also been recommended as a remedy for *worms*, but is of doubtful value. It was formerly largely used in the treatment of *gall stones* with the idea that it stimulated the secretion of bile. The concretions which were passed by these patients, however, were shown to be masses of hardened soap and it is extremely questionable whether the oil has any real value in this disease. Externally it is useful to soften and relax the skin and to protect it against the action of the air. The most extensive use of olive oil is in pharmacy as a constituent of liniments, ointments, cerates, and plasters.

Dose, as a laxative, from one to two fluidounces (30–60 mils).

OLEUM PHOSPHORATUM. Br.

PHOSPHORATED OIL

(ō'lę-ŭm phŏs-phọ-rā'tŭm)

"Phosphorated Oil contains 1 per cent. by weight of Phosphorus. It should be freshly prepared." *Br.*

Huile phosphorée, *Fr. Cod.;* Liniment phosphoré, *Fr.;* Phosphorhaltiges Oel, *G.;* Aceite fosforado, *Sp.*

"Phosphorus, 1 *gramme;* Almond Oil, previously heated to 150° C. (302° F.), cooled and filtered, 98 *grammes;* Oil of Lemon, 1 *gramme*. Add the Phosphorus to the Almond Oil contained in a stoppered bottle capable of holding rather more than the required quantity; warm to about 80° C. (176° F.), and shake until the Phosphorus is entirely dissolved; cool, and add the Oil of Lemon. A clear, pale-yellow liquid, phosphorescent in the dark." *Br.*

Phosphorated oil was not retained in the U. S. P. IX, but has been transferred to the N. F. IV (see Part III).

The U. S. 1890 process, which has been retained in the N. F., does not differ essentially from that of the Br. Pharm. Both are one per cent. solutions; the British formerly contained but 0.75 per cent.

The object of heating the oil is to expel air and traces of water, which would oxidize the phosphorus. The ether not only assists in the preservation of the finished preparation, but is

also of use in rendering the oil less disagreeable to the taste. E. R. Squibb passes a current of carbon dioxide through the oil contained in the bottle in which it is to be kept, to expel the air and prevent oxidation. This is a clear and colorless or but slightly colored oil, phosphorescent in the dark, and having the odor and taste of phosphorus quite distinctly. It should be perfectly free from any particles of undissolved phosphorus. It may be administered in the form of an emulsion, like the official almond emulsion, and flavored with oil of bitter almond, or preferably in capsules; each minim contains about 1-115 of a grain of phosphorus.

Dose, one to two minims (0.06–0.13 mil).

OLEUM PICIS LIQUIDÆ RECTIFICATUM. U. S.

RECTIFIED OIL OF TAR Ol. Pic. Liq. Rect. [Oleum Picis Liquidæ, U. S. VIII Rectified Tar Oil]

(ō'lę-ŭm pī'cĭs lĭq'uį-dæ rĕc-tį-fį-cā'tŭm)

"A rectified volatile oil distilled from Tar." *U. S.*

Huile volatile de Goudron, *Fr.;* Theeröl, Pechöl, *G.*

This oil is prepared by distilling wood tar, the residue left in the still being known as pitch. It represents thoroughly the medicinal properties of tar, and is preferable on account of its less offensive taste. (See *Pix Liquida.*) It is officially described as follows: "Rectified Oil of Tar is a thick liquid having a dark reddish-brown color, and a strong, empyreumatic odor and taste. It is soluble in alcohol, the solution being acid to litmus. Specific gravity: 0.960 to 0.990 at 25° C. (77° F.)." *U. S.*

The thick tarry oil of high viscosity and almost black color, found upon the market and frequently supplied for oil of tar, does not comply with the U. S. P. requirements of sp. gr., as it is usually much heavier than water, while the U. S. P. is lighter.

Uses.—The oil of tar is used chiefly in the treatment of *chronic bronchitis.* Its action is practically the same as that of creosote, which is indeed its most important constituent. It may be administered either in emulsion or by dropping it on sugar. It is often added to boiling water for inhalation in the proportions of five to ten minims to a pint. It is also used externally in various *skin diseases.*

Dose, one to five minims (0.06–0.3 mil), administered in capsule or in emulsion.

Off. Prep.—Mistura Olei Picis, *N. F.;* Petroxolinum Picis, *N. F.;* Unguentum Picis Compositum, *N. F.*

OLEUM PIMENTÆ. U. S.

OIL OF PIMENTA Ol. Piment. [Oil of Allspice Pimento Oil]

(ō'lę-ŭm pī-mĕn'tæ)

"A volatile oil distilled from the fruit of *Pimenta officinalis* Lindley (Fam. *Myrtaceæ*), yielding not less than 65 per cent., by volume, of eugenol [$C_{10}H_{12}O_2$ = 164.10]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Oleum Amomi; Oil of Pimento; Huile volatile (Essence) de Piment de la Jamaïque, *Fr.;* Nelkenpfefferöl, Pimentöl, *G.*

Oil of pimenta was deleted from the British Pharmacopœia 1914.

The berries yield from 1 to more than 4 per cent. of the volatile oil, which as found in commerce is brownish-red, and has the odor and taste of pimenta, though warmer and more pungent. It has a slightly acid reaction.

"Oil of Pimenta is a colorless, yellow or reddish liquid, becoming darker with age and having the characteristic odor and taste of allspice. It is soluble in an equal volume of 90 per cent. alcohol; also soluble in 2 volumes of 70 per cent. alcohol. Specific gravity: 1.018 to 1.048 at 25° C. (77° F.). The optical rotation varies from 0° to −4° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21).

"**Assay.**—Proceed as directed under *Oleum Caryophylli,* using 10 mils of Oil of Pimenta. The residual liquid measures not more than 3.5 mils, indicating the presence of not less than 65 per cent., by volume, of eugenol." *U. S.*

It consists, like oil of clove, of two distinct portions, one a sesquiterpene, $C_{15}H_{24}$, and the other a phenol, *eugenol,* capable of extraction by shaking out with alkaline hydroxide solution. They may be separated by distilling the oil from potassium hydroxide solution. After the hydrocarbon is distilled off the phenol may be obtained by liberation from its combination with sulphuric acid and distilling. It is readily recognized as eugenol, so that oil of pimenta is analogous in its constitution to oil of clove (see *Oleum Caryophylli*). Nothing is known of the constituents which give oil of pimenta its characteristic odor.

Oil of pimenta is given for the same purposes as are the other stimulant aromatic oils.

Dose, from three to six minims (0.2–0.4 mil).

Off. Prep.—Liquor Pepsini Aromaticus, *N. F.;* Spiritus Myrciæ Compositus, *N. F.*

OLEUM PINI PUMILIONIS. U. S.

OIL OF DWARF PINE NEEDLES Ol. Pin. Pumil. [Dwarf Pine Oil]

(ō'lę-ŭm pī'nī pū-mĭ'lį-ō-nĭs)

"A volatile oil distilled from the fresh leaves of *Pinus montana* Miller (*Pinus Pumilio* Haenke) (Fam. *Pinaceæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Oleum Pini, *Br.,* 1898; Oil of Pine; Pine Needle Oil; Latschenkieferöl, Krummholzöl, *G.;* Oleum templinum, Pumiline.

The British Pharmacopœia 1898 replaced fir wood oil by making oil of pine official. This was largely due to the investigations of J. C. Umney (*P. J.,* 1895, 161, 173, 542), who found that the *Pinus Pumilio* (now recognized as *P. montana* Miller) (*Mountain Pine*) furnished an oil of fairly constant character and superior to that from the *Pinus sylvestris* (*Scotch Fir*)

of the British Pharmacopœia 1885. It was not included in the Br. 1914 but is recognized by the U. S. IX. It "is a colorless or faintly yellowish oil having a pleasant, aromatic odor, and a bitter and pungent taste. Specific gravity: 0.853 to 0.869 at 25° C. (77° F.). No portion of the Oil distils below 170° C. (338° F.)." It resinifies on exposure, and in medicinal qualities resembles oil of turpentine, but is milder. Pine oil contains lævo-pinene, lævo-phellandrene, sylvestrene, *bornyl acetate,* and in the last portions of the distillate, cadinene. (Gildemeister and Hoffmann, *Aetherische Oele,* p. 338.) It is supposed that the pine oil owes its odor to the presence of the acetic ester of borneol, which is ordinarily present to the amount of about 3.5 per cent., and Schimmel & Co. (*Schim. Rep.* for Oct., 1897) found in a sample of American fir oil as much as 12.1 per cent.

Uses.—In medicine it may be employed for many of the purposes for which oil of turpentine has been used. As an expectorant in *chronic bronchitis* it may be administered by the mouth but is especially prized as an inhalant because of its pleasant odor. For this purpose a few drops may be placed in boiling water and the vapors inhaled. It has also been employed internally in the treatment of *chronic rheumatism.*

The leaves of the *Pinus sylvestris,* with those of other European firs and pines, by pounding are converted into a fibrous substance, known as *fir wool* (*Fichtenwolle*), which is much used in Germany as a local application in *chronic rheumatism,* the affected part being enveloped in a thick batting of the fir wool, which is also sometimes made into clothing for rheumatic persons. An extract of the leaves is also sold under the name of *fir wool extract,* for use in rheumatism.

Dose of oil of pine needles five to ten minims (0.3–0.6 mil).

OLEUM RICINI. U. S., Br.

CASTOR OIL Ol. Ricin.

(ō'lę-ŭm rĭç'ĭ-nī)

"A fixed oil obtained from the seeds of *Ricinus communis* Linné (Fam. *Euphorbiaceæ*). Preserve it in well-closed containers." *U. S.* "Castor Oil is the oil expressed from the seeds of Ricinus communis, *Linn.*" *Br.*

Huile de Ricin, *Fr. Cod.;* Oleum e semine Ricini, *Fr.;* Oleum Ricini, *P. G.;* Ricinusöl, *G.;* Olio di ricino, *It.;* Aceite de ricino; Oleum Palmæ Christi, *Sp.*

The castor oil plant, or *palma Christi,* is a native of India and is now extensively cultivated in the warmer regions throughout the world. In India there are about seventeen different varieties grown which are grouped into two types. (1) The one consisting of tall shrubs or small trees, being usually planted as a shade for other crops and yielding large seeds which contain an abundance of inferior oil. (2) The second type includes the herbaceous annuals, which, while they produce small yields, yield a much better grade of fixed oil.

The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate, palmately six to eleven lobed, the lobes acute or acuminate and serrate, smooth on both sides, and of a bluish-green color. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the staminate flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, united into fasciculi at their base. In the pistillate the calyx has three or five narrow lanceolate segments, and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish, glaucous capsule, with three projecting sides, covered with tough spines, and divided into three loculi, each containing one seed, which is expelled by the bursting of the capsule. This species of *Ricinus* is a native of the East Indies and Northern Africa, naturalized in the West Indies, and cultivated in various parts of the world, in few countries more largely than in the Middle and Western United States. The flowers appear in July, and the seeds ripen successively in August and September. A decoction or poultice of the leaves is sometimes used as a local galactagogue, and an infusion has been given internally for a similar purpose. (*L. L.,* Dec., 1859.)

1. The Seeds.—These are from 8 to 18 mm. long and 4 to 12 mm. broad, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash color, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish caruncle, from which an obscure longitudinal ridge proceeds to the opposite extremity, known as the raphe. In its general appearance the seed is thought to resemble the insect called the *tick,* the Latin name of which has been adopted as the generic title of the plant. Its variegated color depends upon a very thin pellicle closely investing a hard, brittle, blackish, tasteless, easily separated shell, within which is the kernel, highly oleaginous, of a white color, and of a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts Geiger found, exclusive of moisture, 23.82 parts of envelope, and 69.09 of kernel. These 69.09 parts contained 46.19 of fixed oil, 2.40 of gum, 20.00 of starch and lignin, and 0.50 of albumen. Henry Bower could find no starch, but separated from the seeds an albuminoid principle, which acted with amygdalin and water like emulsin, producing the odor of oil of bitter almond, though in a less degree. (*A. J. P.,* xxvi, 208.) It is highly probable that it is

this principle which, acting as an enzyme on the oily matter of the seeds, gives rise to changes in its nature which render them rancid. (See *Olea Fixa,* p. 810.) G. J. Scattergood found the odor of castor oil to be developed in the beans when bruised with water, and much more powerfully in those long kept than in the fresh. The water distilled from the seeds has a peculiar nauseous odor, quite distinct from that of the oil. (*A. J. P.,* xxvii, 207.)

Taken internally the seeds are powerfully cathartic, and often emetic. Two are sufficient to purge with great violence, and three have produced fatal gastro-enteritis in the adult. After expression of the oil, and treatment with pure alcohol, Calloud found the residue to be powerfully emetic in the quantity of 30 grains, taken in two doses. (*J. P. C.,* 3e sér., xiv, 190.) According to Guibourt, the toxic property pervades the whole kernel, the integuments being inert. The experiments of Scattergood, who found that the water distilled from the seeds is emetic and cathartic, would seem to show that the active principle is volatile, but the researches of Stillmark indicate that it is an enzyme, *ricin,* which is a so-called phytalbumose and has been obtained as a white amorphous powder, and is best dissolved in a 10 per cent. salt solution. The aqueous solution of the pure ricin has a neutral reaction. It is a violent poison. E. L. Boerner (*A. J. P.,* 1876, p. 481) obtained butyric acid by macerating the exhausted marc of the seeds with water until decomposed.

2. The Oil.—This may be extracted from the seeds in three ways: 1, by decoction; 2, by expression; 3, by the agency of alcohol or other solvent.

The process by decoction, which has been practised in the East and West Indies, consists in bruising the seeds, previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. The seeds, it is said, are sometimes roasted, to increase the yield. But by a temperature much above 100° C. (212° F.) the oil is rendered brownish and acrid, and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated; hence it happens that the West India oil has generally a brownish color, an acrid taste, and irritating properties.

The oil is obtained in this country by expression. The following, we have been informed, are the outlines of the process usually employed by those who prepare it on a large scale. The seeds, having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful hydraulic press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed, and the process is completed by boiling with a minute proportion of water, and continuing the application of heat until aqueous vapor ceases to rise, and until a small portion of the liquid, taken out in a vial, continues perfectly transparent when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far, as the oil then acquires a brownish hue and an acrid peppery taste. After the completion of the process, the oil is put into barrels and sent into the market. See article on the preparation of castor oil. (*A. J. P.,* 1879, p. 481.) There is reason, however, to believe that much of the American oil is prepared by merely allowing it to stand for some time after expression, and then drawing off the supernatant liquid. One bushel of good seeds yields five or six quarts, or about 25 per cent. of the best oil. If not carefully prepared, it is prone to deposit a sediment upon standing, and the apothecary may find it necessary to filter it through coarse paper before dispensing it. Perhaps this may be owing to the plan just alluded to of purifying the oil by rest and decantation. We have been told that the oil in barrels usually deposits in cold weather a copious whitish sediment, which is redissolved when the temperature rises. A large proportion of the oil consumed in the eastern section of the Union has been derived, by the way of New Orleans, from Illinois and the neighboring States, where it has been at times so abundant that it has been used for burning in lamps and for lubricating machinery.

The process for obtaining castor oil by means of alcohol has been practised in France, but the product is said to become rancid more speedily than that procured in the ordinary mode. Such a preparation has been employed in Italy, and is asserted to be less disagreeable to the taste, and more effective, than the common oil obtained by expression. According to Parola, an ethero-alcoholic extract and an ethereal or alcoholic tincture of the seeds operate in much smaller doses than the oil, and with less disposition to irritate the bowels or to cause vomiting. (See *Am. J. M. S.,* N. S., xiii, 143.)

Owing to the presence of ricin, "*castor pomace,*" or the oil cake obtained by the extraction of castor oil, is unfit for animal food.

For the process of removing the poisonous principle see *P. J.*, lxviii, 213.

Italian Castor Oil.—The castor oil plant is cultivated throughout Italy, but especially in the neighborhood of Verona, where the oil is prepared with great care and is remarkably free from the peculiar odor and taste which render this medicine so repulsive to many palates. As it is highly desirable, for certain purposes, that the oil should be as free from these properties as possible, it is a point worthy of investigation, why it is that the Italian oil is superior to most commercial varieties of the oil in these respects. The following facts in relation to the mode of preparing the oil practised at Verona, published by H. Groves, of Florence, acquire on this account a special value. One point of importance is that the seeds are used fresh, as the oil rapidly becomes rancid in them when kept. Another fact is that the seeds are entirely deprived of their coating before being submitted to pressure. This is effected by passing them between two revolving wooden rollers, with a winnowing machine beneath, and, to secure the complete absence of integument, they are afterwards assorted by the hand, all being rejected which are not perfectly decorticated. They are then put into hempen bags, which are arranged in layers with a sheet of iron heated to 32.2° C. (90° F.) between them, so as to enable the oil to flow. Lastly, they are submitted to pressure by hydraulic presses. The oil which now flows is of the finest quality. An inferior kind is obtained by pressing the marc at a somewhat higher heat. An interesting and valuable article on the cultivation of the castor bean in the United States appears in the *Proc. P. Ph. A.*, 1916, p. 209, by Joseph L. Lemberger.

Properties.—Pure castor oil is a thick, viscid, colorless liquid, with little odor, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in commerce it is often tinged with yellow and has an unpleasant odor, and parcels are sometimes, though rarely, met with of a brownish color and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque. When exposed to the air in a thin layer, it slowly dries to a varnish-like film. It is heavier than most of the other fixed oils. It differs also from most other fixed oils in being soluble in all proportions in cold absolute alcohol. "Castor Oil is a pale yellowish or almost colorless, transparent, viscid liquid, having a faint, mild odor, and a bland, afterwards slightly acrid and generally nauseating taste. It is miscible with dehydrated alcohol or glacial acetic acid. Specific gravity: 0.945 to 0.965 at 25° C. (77° F.). Castor Oil is only partly soluble in petroleum benzin (distinction from *most other fixed oils*). Castor Oil produces a clear liquid with an equal volume of alcohol (*foreign oils*). Saponification value: not less than 179 nor more than 185 (see Part III, Test No. 9). Iodine value: not less than 83 nor more than 88 (see Part III, Test No. 8)." *U. S.*

"Nearly colorless, or with a yellowish tinge, viscid. Liable to solidify at low temperatures. Slight odor; taste at first bland, but afterwards acrid and unpleasant. Specific gravity 0.958 to 0.970; *saponification value* 177 to 187; *iodine value* 83 to 90; *acid value* not more than 4.0; *refractive index* at 40° C. (104° F.) 1.4695 to 1.4730. Soluble in all proportions of *absolute alcohol*, and in 3.5 parts of *alcohol* (90 per cent.). 10 millilitres shaken with 7 millilitres of *petroleum spirit* in a stoppered glass cylinder form a clear mixture at 15.5° C. (60° F.); on shaking with a further addition of 3 millilitres of *petroleum spirit* a turbid mixture is formed, which becomes clear when maintained for five minutes at 21° C. (69.8° F.), but again becomes turbid when the temperature falls below 18° C. (64.4° F.) (absence of other fixed oils)." *Br.*

Weaker alcohol, of the sp. gr. 0.8425, takes up about three-fifths of its weight. It has been supposed that adulterations with other fixed oils might thus be detected, as the latter are much less soluble in that fluid, but Pereira has shown that castor oil has the property of rendering a portion of other fixed oils soluble in alcohol, so that the test cannot be relied on. (*P. J.*, ix, 498.) Such adulterations, however, are seldom practised in this country. Castor oil is soluble also in ether, and in its weight of glacial acetic acid. Its proximate composition has been repeatedly investigated. The bulk of it is *ricinolein*, $C_3H_5(C_{18}H_{33}O_3)_3$, which is the *ricinoleic acid* ($C_{18}H_{34}O_3$) glyceride. At the same time it also contains a small quantity of tristearin and of the glyceride of dihydroxystearic acid, together with from 0.30 to 0.37 per cent. of unsaponifiable matter. Ricinoleic acid, as obtained from the decomposition of the glyceride, is a viscid oil, which solidifies below 0° C. (32° F.), does not solidify in contact with the air by absorption of oxygen, and is not homologous with oleic or linoleic acid, neither of which is found in castor oil. On warming with 1 part of starch and 5 parts of nitric acid (sp. gr. 1.25) castor oil thickens, owing to the formation of *ricinelaidin*. From this *ricinelaidic acid* may be obtained in brilliant crystals. Ricinoleic acid is converted by potassium hydroxide into caprylic alcohol and sebacic acid, with disengagement of hydrogen, and the same products are obtained by the reaction of potassium hydroxide with the oil itself. (See *J. P. C.*, Août, 1885, 113.) Its purgative property is supposed by Bussy and Lecanu to belong essentially to the oil, and not to any distinct principle which it may hold in solution. According to O. Popp, castor oil differs from most other fixed oils in turning the plane of polarized light to the right. (*A. J. P.*, Aug., 1871, 354; from *A. Pharm.*, 1871.) Various substances containing coloring principles, which they yield to castor oil, produce beautiful fluorescence in that fluid when heated with it, such as logwood, turmeric, camwood, etc. (Charles Horner, *P. J.*, Oct., 1874, p. 282.)

Ricinine is a basic substance, $C_8H_8O_2N_2$,

which is soluble in all of the ordinary solvents and which occurs as colorless crystals optically inactive and neutral in reaction. It is precipitated from aqueous solutions by Mayer's reagent and Wagner's reagent, showing alkaloidal properties thereby. It is not especially toxic.

Buchheim believes the active principle of castor oil to be *ricinoleic acid;* this has been confirmed by the experiments of Hans Meyer (*A. E. P. P.,* xxviii, 1890), who finds that both pure ricinoleic acid and the ricinoleate of glyceryl are active purgatives. Ricinelaidic acid, which Buchheim believed to be inactive, Meyer finds when given in fine emulsion to act as powerfully as does castor oil.

By the action of concentrated sulphuric acid upon castor oil is formed a valuable product known as *"Turkey-red oil,"* much used in dyeing and printing with madder and alizarine. The water-soluble portion of this Turkey-red oil is *ricinoleo-sulphuric acid,* $C_{18}H_{33}O.O.HSO_3$. Turkey-red oil acts as a fixing agent, imparting a superior luster to the fiber dyed with its aid.

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air it is apt to become rancid, and is then unfit for use.

Twombly finds that the best method for removing the odor and taste of castor oil is by washing a cold pressed oil several times with boiling water. After separating, the oil is filtered cold very slowly through a thick layer of powdered animal charcoal. Any effort to quicken the method gives poor results.

Commercially ricin has been employed for the detection of pepsin. For details of the method see Solms. (*Z. K. M.,* 1907.)

Uses.—The cathartic effects of castor oil are due to its ricinoleic acid which is split off in the intestinal tract. This, by gentle irritation of the mucous membrane, excites active peristalsis in the upper bowel and probably also somewhat increases the intestinal secretions, although the main action appears to be due to the increased peristalsis. Because of the thoroughness with which it empties the enteric canal there is on the following day an insufficient accumulation of intestinal contents and hence constipation is liable to follow. Because it cleans out the whole alimentary system and that with relatively small degree of irritation, it is especially valuable in conditions of irritation or inflammation of the bowels, as *colic, enteritis,* or *dysentery;* on account of the tendency to subsequent constipation it is not to be recommended as a habitual laxative. It is habitually resorted to in cases of *pregnant* and *puerperal women,* and is decidedly, as a rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults.

Externally it is useful for its emollient effects in *seborrhea* and other *skin diseases,* having the advantage over other oils of being soluble in alcohol.

The *dose* for an infant is from one to three or four fluidrachms (3.75–11.25–15 mils). It is difficult of administration, from its peculiarly disagreeable taste and from its clamminess and adhesiveness to the mouth. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. A common method of disguising the taste is to give it floating in mint or cinnamon water, but that which we have found, upon the whole, the least offensive is to give it floating on the froth of sarsaparilla syrup mixed with carbonic acid water. Some take it in wine, or spirituous liquors, or the froth of porter, but these are often contra-indicated by their stimulant property. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf sugar, and an aromatic water. Tragacanth has been recommended as producing a better emulsion than gum arabic. Tincture of opium may be added in cases of intestinal irritation. A *castor oil jelly* containing over 90 per cent. of the oil may be made by adding a little stearic acid to the melted oil and then saponifying with a very small amount of an alcoholic solution of sodium hydroxide. This form a jelly-like preparation which may be sweetened with saccharin and flavored with any desired volatile oil. Castor oil may also be beneficially used as an enema, in the quantity of two or three fluidounces (60 or 90 mils), mixed with some mucilaginous liquid. It has been recommended as a local application to the breasts of nursing women, to promote the secretion of milk.

Though prone to become rancid by itself, it loses much of its susceptibility when mixed with lard, and some druggists are said to use it as a substitute for olive oil in ointments and cerates.

Dose, half a fluidounce to two fluidounces (15–60 mils).

OLEUM ROSÆ. Br.

OIL OF ROSE

(ō'lę-ŭm rō'şæ)

"Oil of Rose is the oil distilled from the fresh flowers of Rosa damascena, *Linn.*" *Br.*

Oleum Rosarum; Attar or Otto of Rose; Huile volatile de Rose pâle, *Fr. Cod.;* Essence de Rose, *Fr.;* Oleum Rosae, *P. G.;* Rosenöl, *G.;* Essenza de rose, *It.*

Oil of Rose was not admitted to the U. S. P. IX. Fats and oils saturated with the rose perfume have been used since the earliest times. Of the seven thousand or more cultivated varieties of rose only a few are used for the production of oil. The chief of these is *Rosa damascena,* which is supposed to be a hybrid between *R. gallica* and *R. canina.* The volatile oil from this species is commonly called *attar, otto,* or *essence of roses.* It is prepared on a large scale in Turkey in Europe, especially in the Balkan Mountains, in Egypt, Persia, Cashmere, India, and other countries of the East, but European

and American commerce is at present supplied chiefly from the region constituting the southern slope of the Balkans, and to some extent, from flowers cultivated in Germany. Synthetic Oil of Rose has entered commerce. The Bulgarian production of rose oil for 1913 amounted to 3600 kilos. (*Schim. Rep.*, Oct., 1913.) The roses are gathered in May, and are distilled with the green leaves of the calyx. From thirty to sixty pounds are put into a tinned copper boiler, of the capacity of about 150 pounds, nearly filled with water. The heat is applied over an open fire, and a boiling temperature is continued for two hours, when the first part of the distilled fluid is returned to the boiler, and the process is continued to completion. The oil collects on the top of the water in the receiver, when it is removed from time to time as it accumulates. (*P. J.*, June, 1872, p. 1051.) In the south of France a small quantity of oil of rose is prepared by distilling the petals with water and separating the oil which floats to the surface. The annual output of the oil is small, most of it being marketed in the form of rose water of which over 3,600,000 liters are produced annually. (*Schim. Rep.*, Oct., 1907.)

Oil of rose is furnished in very minute proportion, not more than three drachms having been obtained by Polier in Hindostan, from 100 pounds of the petals. It is usually imported in small bottles, and is very costly. Oil of rose was at one time prepared in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. (*Ph. Cb.*, 1847, p. 783.) Landerer states that at Damascus and in other parts of Asia Minor the oil is prepared by dry distillation. The buds, being collected before sunrise, are placed in a glass retort, and the distillation is effected by a salt water bath, care being taken so to regulate the heat as not to scorch the petals. The water of the fresh roses and their oil come over together, and the latter, floating on the top, is readily separated.

For an account by R. Bauer of Constantinople, of oil of rose, its production, properties, adulteration, etc., see *P. J.*, Dec., 1867, 286; also *A. J. P.*, 1881, 367.

The experiments of Schimmel are said to indicate that the oil of rose can be prepared from German-grown flowers with commercial success. It is affirmed that the product is superior to the Turkish oil in fineness and strength of aroma, and also that it differs in having a higher congealing point, German oil solidifying at 32° C. (89.6° F.), Turkish oil at 20° C. (68° F.). For an account of its production, see *P. J.*, Aug., 1886; also *P. J.*, 1893, 262.

Oil of rose is nearly colorless, or presents some shade of green, yellow, or red, but, according to Polier, the color is no criterion of its value. Its odor is very powerful and diffusive. At 32.2° C. (90° F.) its sp. gr. is 0.832. Alcohol dissolves it, though not freely when cold. It was officially described in U. S. P. VIII as "a pale yellowish, transparent liquid, having the strong, fragrant odor of rose, and a mild, slightly sweetish taste. Specific gravity: 0.855 to 0.865 at 25° C. (77° F.). The addition of 70 per cent. alcohol precipitates the paraffin hydrocarbons of the Oil, but forms a clear solution with its other constituents, the solution being slightly acid to litmus T.S. The congealing point, when determined according to the following method, should be between 18° and 22° C. (64.4° and 71.6° F.). Introduce about 10 mils of Oil into a test-tube of about 15 Mm. diameter; insert a thermometer in such a manner that it touches neither the bottom nor the sides of the tube. Raise the temperature of the Oil in the tube from 4° to 5° above the saturation point by grasping it in the hand, and shake the tube gently. Allow the Oil to cool, and when the first crystals appear, note the temperature. This is regarded as the congealing point; a second test should be made for confirmation." *U. S. VIII.*

"A pale yellow or yellowish-green crystalline mass, semi-solid at ordinary temperatures. Strong, fragrant, rose-like odor; taste sweetish. Specific gravity at 30° C. (86° F.) (compared with *water* at 15.5° C. (60° F.)) 0.854 to 0.862; *optical rotation* –2° to –4°; *refractive index* at 25° C. (77° F.) 1.456 to 1.465; melting point 20° to 23° C. (68°–73.4° F.)." *Br.*

Oil of rose consists of two portions, one liquid, the other solid at ordinary temperatures. These may be separated by freezing the oil and compressing it between folds of blotting paper, which absorbs the liquid oil and leaves the concrete stearopten. The liquid portion is oxygenated, while the solid portion, which is odorless when pure, consists of a mixture of several hydrocarbons, one of which melts at from 35.5° to 36.5° C. (96°–97.7° F.), and is a paraffin of the formula $C_{16}H_{34}$. A sample of oil of rose distilled in Leipsic in 1884 yielded 28 per cent. of this stearopten, an inferior oil distilled in London gave 68 per cent., and a very good oil from the Balkans gave 9.20 per cent. The oxygenated portion consists of the two alcohols, $C_{10}H_{18}O$ geraniol, and $C_{10}H_{20}O$ citronellol, the former constituting 75 per cent. of the oil. The rhodinol of Eckart was a mixture of these two alcohols. (*Schim. Rep.*, April, 1898, 40.) While these two alcohols are mainly found in rose oil in the free state, esters of the same are also present in amounts varying from 2.5 to 3.5 per cent. (Gildemeister and Hoffmann, *Aetherische Oele*, p. 565.) Linalool, citral and phenyl ethyl alcohol are also present in small amounts.

The U. S. P. VIII considered the saponification value as of sufficient importance to incorporate it as an official test, as follows:

Assay.—"Place in a weighing-bottle about 2 mils of the Oil of Rose, and weigh it accurately. Transfer it, with the aid of a little alcohol, to a 100 mil flask, and add 20 mils of half-normal alcoholic potassium hydroxide V.S. Connect the flask with a reflux condenser, and boil the mixture during thirty minutes on a water-bath.

When cool, add 50 mils of distilled water and a few drops of phenolphthalein T.S., and titrate with half-normal sulphuric acid V.S. Subtract the number of mils of half-normal sulphuric acid V.S. required, from 20 (the 20 mils of half-normal alcoholic potassium hydroxide V.S. taken), multiply the difference by 27.87, and divide by the weight of the Oil to obtain the saponification value." *U. S. VIII.*

Oil of santal, other volatile oils, fixed oils, spermaceti, etc., are said to be added almost universally as adulterations. The volatile additions may be detected by their not being concrete; the fixed, by the greasy stain they leave on paper when heated. Guibourt has offered certain tests by which he thinks the purity of the oil may be determined. (See *A. J. P.*, xxi, 318.) A. Ganswindt recommends the following tests. Agitate 1 drop of the oil with 45 Gm. of warm water, and sprinkle the solution in a moderately warm room, which will soon be filled with a rose odor, in which foreign odors may be detected without difficulty. An adulteration with a fixed oil produces a permanent grease stain upon paper, and spermaceti is left behind on the evaporation of a few drops of the oil from a watch crystal in a water bath. On mixing a few drops of pure oil of rose with an equal bulk of sulphuric acid, the rose odor is not changed, but oils used for adulteration change their odor, which becomes apparent in the rose odor. Or 5 drops of the oil are mixed in a dry test tube with 20 drops of pure concentrated sulphuric acid; when the mixture is cool it is agitated with 20 Gm. of absolute alcohol, when a nearly clear solution should be obtained, which, heated to boiling, remains clear yellowish-brown on cooling. In the presence of the oil of rose geranium, palmarosa, etc., the alcoholic mixture is turbid, and on standing separates a deposit without becoming clear. (*Seifens. Ztg.*, 1881, p. 32; *A. J. P.*, May, 1881.) The oil of one of the sweet scented *Pelargoniums*, perhaps the *rose geranium*, is much employed in Turkey for the purpose of adulteration. According to Hanbury, who appears to have thoroughly investigated the subject, two substances especially are used in Constantinople for adulterating the oil—one spermaceti, the other a volatile oil produced by certain grasses in the East Indies belonging to the genus *Andropogon*, large quantities of which are exported from Bombay, partly directly to Europe, partly through the Arabian Gulf, whence it reaches Constantinople. The same oil is imported into London under the name of *Turkish essence of geranium*, or *geranium oil*.

Tedermann (*Zeit. An. Chem.*, 1895, 5) reached the conclusion, after much experimenting, that there is no reliable chemical or physical test for the adulteration of oil of rose with geranium oil. The sense of smell, according to Conroy, furnishes the best means of determining the quality; he recommends the dissolving of one drop of oil of rose in twenty drops of alcohol, pouring the solution in one fluidounce of warm water, shaking, and comparing the odor with that of a standard sample treated in the same way. (*P. J.*, 1896, 474; see also *C. D.*, 1897, 53.) O. Helm (*A. Pharm.*, 1885) states that the test with a mixture of five parts of chloroform and twenty parts of alcohol cannot be relied upon, as no separation of crystalline scales took place in four different rose oils which were doubtless genuine. But Flückiger, on the other hand, stated that in an experience of many years it had never failed. According to Bauer, the best tests of the purity of the oil are found in its congealing, in five minutes, at a temperature of 12.5° C. (54.5° F.), and its crystallizing, as a solid mass, in light, shiny plates, present everywhere throughout the liquid. These crystals are truncated semi-sided prisms, the angles of which are unequal, and which must be classed in the rhombic system. This stearoptene melted and allowed to cool, crystallizes in a manner so complete that the microscope can readily reveal the presence of foreign substances, such as spermaceti, fatty bodies, wax, and other analogous amorphous substances.

Oil of rhodium (*Oleum ligni Rhodii, Aspalathum*). This oil was attributed by Lewis to the *Convolvulus Scoparius*, but according to Holmes (*Perfume and Essential Oil Record*, 1911, ii, p. 29) is the product of a species of *Genista*, either *G. canariensis* or *virgata*. It is used to adulterate oil of rose. Guaiac wood oil is also occasionally used for the same purpose. A factitious oil of rhodium is sometimes sold as a lure for rats and other animals. It is made from oil of copaiba flavored with a trace of oil of rose. The synthetic oil of rose has largely replaced that obtained by distillation.

Oil of rose may be added, as a grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments.

Off. Prep.—Unguentum Aquæ Rosæ, *Br.*

OLEUM ROSMARINI. U. S., Br.

OIL OF ROSEMARY Ol. Rosmar. [Rosemary Oil]

(ō'lē-ŭm rŏs-mă-rī'nī)

"A volatile oil distilled from the fresh flowering tops of *Rosmarinus officinalis* Linné (Fam. *Labiatæ*), yielding not less than 2.5 per cent. of ester, calculated as bornyl acetate [$C_{10}H_{17}C_2H_3O_2 = 196.16$], and not less than 10 per cent. of total borneol [$C_{10}H_{17}OH = 154.14$]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Rosemary is the oil distilled from the flowering tops of Rosmarinus officinalis, *Linn.*" *Br.*

Oleum Rorismarini, Oleum Anthos; Huile volatile de Romarin, *Fr. Cod.*; Essence de Romarin, *Fr.*; Oleum Rosmarini, *P. G.*; Rosmarinöl, *G.*; Essenza di rosmarino, *It.*; Esencia de romero, *Sp.*

The fresh leaves of rosemary yield, according to Baumé, 0.26 per cent. of volatile oil, but the percentage is rated much higher by others. Schimmel & Co. obtained by distillation

from dry French rosemary flowers 1.4 per cent. of oil.

This oil is colorless, with an odor similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0.911, but reduced to 0.8886 by rectification (0.894 to 0.912, *U. S.*). Buignet gives the sp. gr. of the rectified oil at 0.896, and states that it is moderately dextrogyrate. Its reaction is neutral. It is soluble in all proportions in alcohol of 0.830, but requires for solution at 17.7° C. (64° F.) forty parts of alcohol of 0.887. (Berzelius.) It is officially described as "a colorless or pale yellow liquid, having the characteristic odor of rosemary, and a camphoraceous taste. It is soluble in 10 volumes of 80 per cent. alcohol. Specific gravity: 0.894 to 0.912 at 25° C. (77° F.)." *U. S.*

"Colorless or pale yellow. Odor that of rosemary; taste warm, camphoraceous. Specific gravity 0.895 to 0.920; *optical rotation* −2° to +15°; *refractive index* at 25° C. (77° F.) 1.463 to 1.473. Soluble in 1 part of *alcohol* (90 per cent.), and in 5 to 10 parts of a mixture of equal volumes of *alcohol* (90 per cent.) and *alcohol* (70 per cent.). Contains not less than 10 per cent. of total *alcohols*, calculated as borneol, $C_{10}H_{18}O$, and not less than 1.8 per cent. of *esters*, calculated as bornyl acetate, $C_{10}H_{17}C_2H_3O_2$." *Br.*

Assay for Esters and Total Borneol.—"Proceed as directed for menthyl acetate and for menthol under *Oleum Menthæ Piperitæ*, using 10 mils of Oil of Rosemary for each assay. In place of the factor and formula for menthyl acetate and menthol, respectively, under *Oleum Menthæ Piperitæ* use the factor 9.808 in calculating the percentage of bornyl acetate and the following formula in calculating the percentage of borneol.

$$\text{Percentage of borneol} = \frac{A \times 7.707}{B - (A \times 0.021)}$$

In which *A* is the result obtained by subtracting the number of mils of half-normal sulphuric acid V.S. required in the titration from the number of mils of half-normal alcoholic potassium hydroxide V.S. originally taken, and *B* is the weight of acetylized oil taken." *U. S.*

Kane gives its sp. gr. at 0.897, its boiling point at 185° C. (365° F.). Kept in bottles imperfectly stoppered, it deposits a stearopten, sometimes amounting, according to Proust, to one-tenth of the oil. Both Gladstone and Flückiger find that most of the oil consists of a hydrocarbon of the composition $C_{10}H_{16}$, boiling at 165° C. (329° F.), and Schimmel & Co. (*Schim. Rep.*, Oct., 1889) identified this hydrocarbon as pinene, but there is a smaller fraction boiling at from 200° to 210° C. (392°–410° F.), which at low temperatures deposits a camphor, $C_{10}H_{18}O$, identified as borneol. Weber examined oil of rosemary in Wallach's laboratory (*Ann. Ch. Ph.*, ccxxxviii, 89), and found that the fraction boiling between 176° and 182° C. (348.8°–359.6° F.) contains cineol, $C_{10}H_{18}O$. The oil is therefore recognized at present as containing d-pinene, camphene, cineol, borneol (10–15 per cent.), and camphor. According to Flückiger (*A. J. P.*, 1885, 132), from 20,000 to 25,000 kilogrammes of oil of rosemary were produced in Grasse every year. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol, the oil of rosemary is dissolved, and that of turpentine left. This oil is stimulant, but is employed chiefly as an ingredient in rubefacient liniments. For a case of fatal poisoning, see *A. J. P.*, xxiii, 286.

Dose, three to six minims (0.2–0.4 mil).

OLEUM SANTALI. U. S., Br.

OIL OF SANTAL. Ol. Santal. [Oil of Sandalwood Santalwood Oil]

(ō'lē-ŭm săn'tă-lī)

"A volatile oil distilled from the wood of *Santalum album* Linné (Fam. *Santalaceæ*), yielding not less than 90 per cent. of alcohols, calculated as santalol [$C_{15}H_{26}O$ = 222.21]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Oil of Sandal Wood is the oil distilled from the wood of Santalum album, *Linn.*" *Br.*

Oleum Ligni Santali; Oleum Santali Flavi; Oil of Sandal Wood; Huile volatile (Essence) de Santal, *Fr.*; Oleum Santali, *P. G.*; Ostindisches Sandelholzöl, Santelöl, *G.*; Esencia de sandalo, *Sp.*

Under the name of sandalwood various drugs of diverse origin and character find their way into commerce. Of these, the wood of the *Pterocarpus santalinus* is described in this book under its official name of *Santalum Rubrum*, or *Red Saunders*. *Sandal wood bark*, which is believed by H. Stieren to be obtained from some species of *Myroxylon* or *Myrospermum*, is described as occurring in irregular, more or less smooth or unevenly corrugated pieces, of a light, whitish-cinnamon color, with dark, hard epidermis, and of an agreeable, custard-like odor, and an aromatic, slightly acrid, balsamic, bitterish taste. From it Stieren obtained over fifteen per cent. of a clear substance resembling Peruvian balsam. This bark is used for burning in churches as a substitute for frankincense, and bears no relation to sandalwood proper. (*P. J.*, xv, 680.) A sandal wood is yielded by the *Fusanus spicatus* (*S. Cygnorum*) and *F. acuminatus* (*S. acuminatum*) of Australia, whence it is shipped in large quantities to China. An oil distilled from this wood, now coming into the European market, is said to be less odorous than the official product.

Other varieties of sandal wood are collected in the Hawaiian Islands from *Santalum Freycinetianum* Gaud., and *S. pyrularium* A. Gray; in the Fiji Islands from *S. Yasi* Seem.; in New Caledonia from *S. austrocaledonicum* Vieillb.; and in Queensland from *Eremophila Mitchelli* Benth. (Fam. *Myoporaceæ*). For an

account of the sandal wood oil industry of Western Australia, see *C. D.*, 1898, 708. For elaborate microscopic descriptions of the sandalwoods, method of obtaining the oil, etc., see various papers in the *P. J.*, vol. xvi; also *Bull. Pharm.*, 1895, 55. West Australian sandalwood is derived, according to Parry (*C. D.*, 1898, 11), from four species of Santalum, *S. Cygnorum* Miq. (*Fusanus spicatus* R. Br.), *S. lanceolatum* Schlecht (*F. spicatus* R. Br.), *S. acuminatum* A.DC. (*F. acuminatus* R. Br.), and *S. persicarum* F. Muell. (*F. persicarius* F. Muell.), *Venezuelan sandal wood*, the source of the so-called *West Indian sandal wood* of commerce, is, according to E. M. Holmes (*P. J.*, lxii), obtained from the *Schimmelia oleifera* Holmes, now recognized as *Amyris Balsamifera* L. (Fam. *Rubaceæ*). A tree-like shrub, *Osyris tenuifolia* Engl., belonging to the *Santalaceæ*, and a native of East Africa, is said to yield a wood which is very similar to that of the genuine Indian sandal wood. (*P. J.*, 60.)

The *Santalum album*, which yields the official oil, is a small tree twenty or thirty feet high, a native of the mountainous portions of India and of various islands of the Eastern Archipelago, but cultivated in India for the sake of its oil. J. L. Pigot furnished an interesting account of sandalwood cultivation accompanied by a map. (*Schimmel's Report*, 1900.)

Oil of santal is distilled in the United States, Germany, England, and India, the ordinary method of steam distillation being applied after the wood has been reduced to small particles by chipping or grinding. According to the Indian Pharmacopœia the yield of oil is about 2.5 per cent. Oil of santal is habitually adulterated, castor oil and other fixed oils being added, and on the continent of Europe by the volatile *oil of cedar*, which is obtained by distilling the chips left in the making of lead pencils. Chapoteaut (*Bull. Soc. Chim.*, 37, p. 353) found two constituents, one of which he calls *santalol*, $C_{15}H_{26}O$, boiling at 310° C. (590° F.), and the other *santalal*, $C_{15}H_{24}O$, boiling at 300° C. (572° F.). Both of these are decomposed by distilling over phosphoric anhydride, the one yielding $C_{15}H_{24}$, boiling point 260° C. (500° F.), and the other $C_{15}H_{22}$, boiling point 245° C. (473° F.). Sesquiterpenes are also believed to be present in oil of santal. A specimen of oil of santal from South Australia, examined by Schimmel & Co. (*Schim. Rep.*, Oct., 1891), afforded a white crystalline principle, melting at 104° to 105° C. (219.2°–221° F.), which crystallized out in the oil. Parry (*P. J.*, lv, p. 118) found that a portion of the oil was saponifiable, so he assumed the presence of esters of santalol. The U. S. Pharmacopœia describes the oil of santal as "a pale yellow, somewhat thick liquid, having the characteristic odor and taste of sandalwood. It is soluble in 5 volumes of 70 per cent. alcohol, forming a solution which is slightly acid to litmus. Specific gravity: 0.965 to 0.980 at 25° C. (77° F.). The optical rotation varies from –15° to –20° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)." *U. S.*

"Pale yellow or nearly colorless, somewhat viscid in consistence. Aromatic odor; taste unpleasant. Specific gravity 0.973 to 0.985; *optical rotation* –13° to –21°; *refractive index* at 25° C. (77° F.) 1.498 to 1.508. Soluble in 6 parts of *alcohol* (70 per cent.) at 20° C. (68° F.). Contains not less than 90 per cent. of total *alcohols*, calculated as santalol, $C_{15}H_{24}O$." *Br.*

Assay.—"Proceed as directed for menthol under *Oleum Menthæ Piperitæ*, using 10 mils of Oil of Santal. Use the following formula in calculating the percentage of santalol in place of that given for menthol under *Oleum Menthæ Piperitæ*.

$$\text{Percentage of santalol} = \frac{A \times 11.11}{B - (A \times 0.021)}$$

In which *A* is the result obtained by subtracting the number of mils of half-normal sulphuric acid V.S. required in the titration from the number of mils of half-normal alcoholic potassium hydroxide V.S. originally taken, and *B* is the weight of acetylized oil taken." *U. S.*

The following equations represent the reactions involved in the official assay:

$$C_{15}H_{25}OH + (C_2H_3O)_2O = C_{15}H_{25}OCOCH_3 + CH_3CO_2H$$

Santalol + Acetic anhydride = Santalol acetate + Acetic acid

$$C_{15}H_{25}O.COCH_3 + KOH = C_{15}H_{25}OH + CH_3CO_2K.$$

Santalol acetate + Potassium hydroxide = Santalol + Potassium acetate.

In a number of specimens examined by Holmes (*P. J.*, xvi, 821) the sp. gr. varied from 0.96 to 0.99. The sp. gr. of the oil of cedar wood, according to Ince, is 0.948. A large percentage of it may be added to the oil of santal without affecting its density sufficiently to be detected. Holmes states that the presence of more than 10 per cent. of the cedar oil can be recognized through the different solubilities of the oils in alcohol. (See *P. J.*, xvi, 820.) R. A. Cripps, after a thorough examination of the oils in the London market (see *P. J.*, 1892, 461), gives this test: "Two drops of the oil added to six drops of nitric acid, sp. gr. 1.5, on a white tile, should give a yellow to bright reddish-brown coloration, without any green, indigo, or violet tint at the edges during five minutes. For complete saponification in alcoholic solution, it requires not more than 1 per cent. of potassium hydrate." (See also *A. J. P.*, 1893, 20; *Schim. Rep.*, Oct., 1893; *P. J.*, 1895, 118; *West. Drug.*, 1897, 262.) West India oil can be distinguished from the genuine oil by its deviating the plane of polarization to the *right* instead of to the *left*. (*Pharmacographia.*) In two specimens of oil of santal, sp. gr. 0.9649 and 0.9573, F. H. Alcock found strong fluorescence. (*P. J.*, 1886, 923.)

Oil of amyris is the name commercially applied to the "so-called" West Indian sandalwood oil. This adulterant and substitute (which

may be added in amounts up to 5 per cent. without fear of detection) has a sp. gr. of 0.955 to 0.965, an optical rotation of + 25° to + 30° and contains from 30 to 40 per cent. of alcohols capable of being estimated and calculated as santalol by the official method of assay. One of its principal characteristics in a state of purity is its insolubility in 70 per cent. alcohol. Vansoden (*Ph. Ztg.*, 1900, 45, 878) reports the presence of a sesquiterpene alcohol named by him *amyrol,* and having the composition $C_{15}H_{26}O$.

Uses.—The oil of sandalwood is used largely as a perfume. In medicine its chief use is in *gonorrheal urethritis,* although it is sometimes employed in *chronic bronchitis* and *cystitis.* Its general antibacterial power is comparatively weak, but it has special relations towards certain micro-organisms; thus in the experiments of Jordan (*B. M. J.*, Sept. 13, 1913) twenty minims of oil of sandal wood three times a day had practically no effect on the growth of *B. coli* in the urine, but markedly retarded the multiplication of staphylococci. It was first recommended in medicine by Thomas B. Henderson who, however, is said to have used the oil of *S. myrtifolium.*

Dose, five to twenty minims (0.6–1.3 mils), in emulsion, or in capsule, three or four times a day.

OLEUM SASSAFRAS. U. S.

OIL OF SASSAFRAS Ol. Sassaf. [Sassafras Oil]

(ō'lę-ŭm săs'są-frăs)

"A volatile oil distilled from the root of *Sassafras variifolium* (Salisbury) O. Kuntze (Fam. *Lauraceæ*). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Huile volatile (Essence) de Sassafras, *Fr.;* Sassafrasöl, *G;* Esencia de sasafras, *Sp.*

The proportion of oil yielded by the root of sassafras is variously stated at from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopœia, would afford a larger amount. The usual yield is said by Sharp to be one pound from three bushels of the root. From fifteen to twenty thousand pounds were sent annually, before 1861, to the Baltimore market. (*A. J. P.*, Jan., 1863, p. 53.) The root, chopped fine by machinery, has steam forced through it in a closed tub, and the oil is then distilled in the ordinary way. 800 pounds of unrectified oil are said to be obtained from 40,000 pounds of root. (*M. S. Rep.*, Aug. 26, 1871.) The oil is of a yellow color or colorless, becoming reddish by age. It has the fragrant odor of sassafras, with a warm, pungent, aromatic taste, and a neutral reaction. It is among the heaviest of the volatile oils, having the sp. gr. of 1.094, or 1.087 at 15° C. (59° F.) on the authority of Buignet, who states also that it is very slightly dextrogyrate. Oil of sassafras is officially described in the United States Pharmacopœia IX as "a yellow or reddish-yellow liquid, having the characteristic odor and taste of sassafras. It is soluble in 2 volumes of 90 per cent. alcohol, forming a solution neutral to litmus. Specific gravity: 1.065 to 1.077 at 25° C. (77° F.). The optical rotation varies from +3° to +4° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)." *U. S.*

The most complete investigation of sassafras oil is that made by Power and Kleber in 1896. (*Schim. Rep.*, April, 1896.) They find it to have the following composition: safrol, $C_{10}H_{10}O_2$, about 80 per cent.; pinene and phellandrene, $C_{10}H_{16}$, about 10 per cent.; dextrogyrate camphor, $C_{10}H_{16}O$, about 6.8 per cent.; eugenol, $C_{10}H_{12}O_2$, about 0.5 per cent.; a high boiling portion consisting of cadinene and residue, 3 per cent. They say that the hydrocarbon constituent of sassafras oil, to which Grimaux and Ruotte gave the name of *safrene,* is, as just stated, a mixture of pinene and phellandrene. *Safrol* crystallizes well in hard four- or six-sided prisms, with the odor of sassafras. It liquefies at 11° C. (51.8° F.), boils at 232° C. (449.6° F.), has a sp. gr. of 1.106, and is destitute of rotatory power. Variation in the sp. gr. of oil of sassafras may often arise through the congelation and separation of safrol, or through stratification. (LaWall and Pursel, *A. J. P.*, 1898, 340.) Flückiger ascertained that safrol was one of those remarkable bodies which are capable of existing either in a solid or in a fluid condition long after they have passed their freezing or their melting point. Chemically, it has been found to be the *methylene ether of allyl-dioxybenzene.* Safrol appears to be widely distributed in the vegetable kingdom, probably existing in the bark of the *Mespilodaphne Sassafras,* also in the *Puchury* or *Sassafras nuts* (see *Pichurim Beans,* Part II), both of Brazil, as well as in the barks of *Atherosperma moschatum* and of *Beilschmiedia obtusifolia* of Australia, and in the bark of *Doryphora Sassafras* of New Caledonia. The bark described by Dymock as that of *Beilschmiedia fagifolia,* according to the researches of E. S. Hooper, contains saponin and probably is not derived from Beilschmiedia or any other genus of the *Lauraceæ.* (*P. J.*, lxxii.) Safrol is now commercially extracted from oil of camphor, and it probably could be obtained from the oil of various species of the genus *Cinnamomum.* (See *P. J.*, June, 1887.)

Uses.—Oil of sassafras is chiefly used for flavoring purposes, but has physiological properties similar to those of the oil of clove and other allied volatile oils, and may be used for similar purposes. It is a powerful antiseptic and has been highly praised by Peck (*J. A. M. A.*, 1899, xxxii, 6) as a dental disinfectant.

A teaspoonful of it produced in a young man vomiting, collapse, somewhat dilated pupils, and pronounced stupor. (*Cincinnati Lancet-Clinic,* Dec., 1888.) According to the experiments of

A. Heffter (*Atti Dell' XI. Congres. Med. Internaz.*, iii, 1894), safrol is slowly absorbed from the alimentary canal, and escapes through the lungs unaltered and through the kidneys oxidized into *piperonalic acid.* When taken in sufficient dose, it quickly kills by a centric paralysis of respiration, preceded by great depression of the circulation, and when taken in smaller yet toxic amount, it causes death by widespread fatty degeneration of the heart, liver, kidneys, etc. Its isomer, *isosafrol,* is in warm-blooded animals much less active as a poison than is safrol, and is chiefly eliminated as *piperonalic acid.*

Dose, of oil of sassafras, two to six minims (0.12–0.4 mil).

OLEUM SESAMI. U. S., Br.

SESAME OIL. Ol. Sesam. [Teel Oil, Benne Oil]

(ō'le-ŭm sĕ'sa-mī)

"A fixed oil obtained from the seeds of one or more cultivated varieties of *Sesamum indicum* Linné (Fam. *Pedaliaceæ*). Preserve it in well-closed containers." *U. S.* "Sesame Oil is the oil expressed from the seeds of Sesamum indicum, *Linn.*" *Br.*

Sesame oil, which was official in the U. S. P. 1890, was restored to an official position by the U. S. P. IX. It is reputed by many pharmacists to resist rancidity better than other fixed oils of its class. It is especially recommended by Prof. Otto Raubenheimer, of Brooklyn. It is officially described in the U. S. Pharmacopœia as "a pale yellow, oily liquid, almost odorless, and having a bland taste. It is slightly soluble in alcohol, miscible with ether, chloroform, petroleum benzin, or carbon disulphide. Specific gravity: 0.916 to 0.921 at 25° C. (77° F.). Shake 1 mil of the Oil for half a minute with a solution of 0.1 Gm. of sugar in 10 mils of hydrochloric acid; the acid layer becomes bright red and changes to dark red on standing. Blue litmus paper previously moistened with alcohol is not more than slightly reddened by 2 mils of the Oil (*free acid*). Mix 5 mils of the Oil in a test tube with 5 mils of a mixture of equal volumes of amyl alcohol and a 1 per cent. solution of sulphur in carbon disulphide and immerse the test tube to one-third of its depth in a boiling saturated aqueous solution of sodium chloride; no reddish color develops in fifteen minutes (*cottonseed oil*). Saponification value: not less than 188 nor more than 193 (see Part III, Test No. 9). Iodine value: not less than 103 nor more than 112 (see Part III, Test No. 8)." *U. S.*

"Pale yellow. Faint odor; taste bland. Specific gravity 0.921 to 0.924; *saponification value* 189 to 193; *iodine value* 103 to 114; *acid value* not more than 8; *refractive index* at 40° C. (104° F.) 1.4650 to 1.4675. When a mixture of 2 millilitres of the Oil and 1 millilitre of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute, and allowed to stand for five minutes, the acid layer becomes pink. When 1 millilitre of the Oil and 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* are boiled for twenty minutes in a flask provided with a reflux condenser, set aside for twenty-four hours at a temperature not exceeding 15.5° C. (60° F.), and afterwards heated on a water-bath for three minutes, the solution does not deposit crystals on standing for a further twenty-four hours (absence of arachis oil). When 2 millilitres of the Oil are mixed with 1 millilitre of *amylic alcohol* and 1 millilitre of a solution (1 in 100) of *precipitated sulphur* in *carbon disulphide,* and the mixture heated in a test-tube immersed in boiling *water,* no red color is developed within fifteen minutes (absence of cotton seed oil). In India, and in the Eastern, African, and North American Divisions of the Empire, Sesame Oil may be employed in making the official Liniments, Ointments, Plasters, and Soaps for which Olive Oil is directed to be used." *Br.*

Benne Oil, or *Teel Oil,* is inodorous, of a bland, sweetish taste and a neutral reaction, and will keep long without becoming rancid. Flückiger found that 76 per cent. of the oil consists of olein, and that the solid portions yield on saponification palmitic, stearic, and myristic acids. Linoleic acid was afterward discovered in the oil. The oil also contains a small quantity of what is probably a resinoid substance, which may be removed by glacial acetic acid or alcohol. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It is not a drying oil. Villavecchia and Fabris (*Zeit. für Ang. Chem.*, 1893, 505) have investigated sesame oil, and find, in addition to the main constituents before mentioned, a higher alcohol of the formula $C_{25}H_{44}O$, fusing at 137° C. (278.6° F.), a finely crystallizing substance of the formula $C_{11}H_{12}O_3$, fusing at 123° C. (253.4° F.), which substance they name *sesamin,* and a thick uncrystallizable oil, non-nitrogenous, which is the cause of the cherry-red coloration which sesame oil shows with hydrochloric acid and sugar. Tocher (*P. J.*, 1893, 700), after analyzing *sesamin* and determining its molecular weight by Raoult's method in benzene and glacial acetic acid, maintains that its formula should be $C_{18}H_{18}O_5$. Tocher, as quoted by Lewkowitsch (*Chem. Anal. of Oils, Fats, and Waxes,* 2d ed., 389), also believes that the higher alcohol mentioned is cholesterol. "When cooled to –3° C. (26.6° F.) it becomes thick, and at –5° C. (23° F.) it congeals to a yellowish-white mass. Concentrated sulphuric acid converts it into a brownish-red jelly. If 5 mils of the Oil be shaken with an equal volume of concentrated hydrochloric acid, the latter will usually assume a bright emerald-green color, especially if the Oil has been exposed for some time to the action of air and light." Soltzien recommends stannous chloride solution for testing benne oil. (*Proc. A. Ph. A.*, 1897, 195.) According to Schaedler, if one mil of pure benne oil is shaken with one mil of pure hydrochloric acid, sp. gr. 1.125, and one

gramme of cane sugar, a rose-red color is developed in fifteen minutes, changing to violet in twenty-five minutes, and increasing in intensity until, after five hours, the acid has assumed a violet color corresponding in intensity to that of a solution of iodine in carbon disulphide or in chloroform. In the case of all other fixed oils, this color reaction does not begin until after three-quarters of an hour. Olive and almond oils containing as little as one-fourth per cent. of benne oil exhibit the reaction in from twenty to twenty-five minutes. The failure of some experimenters to find the reactions available rests upon the fact that they searched for the color in the oil, and not, as they should have done, in the acid. (*A. Pharm.*, 1887, p. 185.) Benne oil was known to the ancient Persians and Egyptians, and is esteemed by the modern Arabs and other people of the East both as food and as an external application to promote softness of the skin. It is laxative in large doses.

The name sesame oil is also sometimes applied to the oil from the cruciferous seed of *Camelina sativa.*

OLEUM SINAPIS VOLATILE. U. S., Br.

VOLATILE OIL OF MUSTARD Ol. Sinap. Vol. [Mustard Oil]

(ō'lę-ŭm sĭ-nā'pĭs vŏ-lą-tĭ'lē)

"A volatile oil produced synthetically or obtained from the seed of *Brassica nigra* (Linné) Koch (Fam. *Cruciferæ*) (freed from fatty oil) by maceration with water and subsequent distillation. It yields not less than 92 per cent. of allyl isothiocyanate [C_3H_5SCN = 99.12]. The label must indicate whether the Oil has been made synthetically or obtained from black mustard. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Volatile Oil of Mustard is the oil obtained by distillation from black mustard seeds, deprived of most of their fixed oil and macerated in water for several hours." *Br.*

Oleum Sinapis, *Br.* 1885; Oleum Sinapis Æthereum; Oil of Mustard; Huile volatile (Essence) de Moutarde, *Fr.;* Oleum Sinapis, *P. G.;* Senföl, Aetherisches Senföl, *G.;* Essenza di senape, *It.;* Esencia de mostaza negra, *Sp.*

The volatile oil of mustard is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is "a colorless or pale yellow, strongly refractive liquid, having a very pungent and irritating odor and an acrid taste. *Great caution should be exercised in smelling this Oil. It should not be tasted except when highly diluted.* Specific gravity: 1.013 to 1.020 at 25° C. (77° F.). It is optically inactive. The Oil distils completely between 148° and 154° C. (298.4°–309.2° F.), and both the first and last portions of the distillate have nearly the same specific gravity as the original Oil (*alcohol, chloroform, petroleum, or fatty oils*). The addition of a drop of ferric chloride T.S. to the Oil, diluted with several volumes of alcohol, does not produce a blue coloration (*phenols*)." *U. S.*

"Assay.—Dilute about 4 mils of Volatile Oil of Mustard, accurately weighed, with sufficient alcohol to make exactly 100 mils. Transfer 5 mils of this solution to a 100 mil measuring flask, and add 50 mils of tenth-normal silver nitrate V.S. and 5 mils of ammonia water. Stopper the flask, connect it with a reflux condenser and heat it on a water bath during one hour. Allow it to cool, dilute the contents of the flask with distilled water to the 100 mil mark, mix well and filter. Add 4 mils of nitric acid and 2 mils of ferric ammonium sulphate T.S. to 50 mils of the filtrate and titrate the excess of the silver nitrate with tenth-normal potassium sulphocyanate V.S. When calculated from the weight of Oil taken for the assay it shows not less than 92 per cent. of allyl isothiocyanate. Each mil of tenth-normal silver nitrate V.S. consumed corresponds to 0.004956 Gm. of allyl isothiocyanate." *U. S.*

"Colorless or pale yellow. Intensely penetrating odor. Produces almost immediate vesication when applied to the skin. Specific gravity 1.014 to 1.025. Distils between 148° and 156° C. (298.4° and 312.8° F.). Contains in 100 millilitres not less than 92 grammes of allyl isothiocyanate, C_3H_5NCS, as determined by the following process:—

"With *alcohol* (90 per cent.) prepare a solution containing 1 gramme of the Oil in 50 millilitres. To 5 millilitres of this solution in a 100 millilitre flask add 30 millilitres of *N/10 solution of silver nitrate* and 5 millilitres of *solution of ammonia.* Heat on a water-bath to 80° C. (176° F.) for thirty minutes, shaking frequently; cool to 15.5° C. (60° F.), make up to exactly 100 millilitres with *water,* and filter. To 50 millilitres of the filtrate add 4 millilitres of *nitric acid,* a few drops of *solution of ferric sulphate,* and sufficient *N/10 solution of ammonium thiocyanate* to produce a permanent red color. Not more than 5.7 millilitres of the latter reagent are required (presence of not less than 92 grammes of allyl isothiocyanate in 100 millilitres of the Oil)." *Br.*

Will considers volatile oil of mustard to be *allyl isosulphocyanate,* $CSNC_3H_5$ (*allyl isothiocyanate*), it being related to oil of garlic, which is sulphide of allyl. It sometimes contains allyl cyanide and traces of carbon disulphide. (*Chem. Gaz.*, Nos. 62 and 64.) It is the principle upon which black mustard seeds depend for their activity. Volatile oil of mustard was first produced artificially by Berthelot and S. de Luca, by treating allyl iodide, C_3H_5I, with an alcoholic solution of potassium sulphocyanate. It is now extensively manufactured artificially by this method. What first forms is allyl sulphocyanate, which is not identical with, but only an isomer of, mustard oil (allyl isosulphocyanate). But if the sulphocyanate be heated to its boiling point 161° C. (321.8° F.) the thermometer sinks rapidly to 150° C. (302° F.), because of the change into the isosulphocyanate, or mustard oil. This change also takes place spontaneously at summer temperature. A small quantity of

carbon disulphide seems always to be produced at the same time. Allyl iodide is procured by treating glycerin with phosphorus iodide. According to Zeller, the seeds yield from 0.33 to 0.63 per cent. of the oil. Will and Koerner in 1863 explained the occurrence of this allyl isosulphocyanate in mustard oil. It does not occur ready formed in the seeds, but is produced by the decomposition of a compound, *sinigrin* (*potassium myronate*), occurring there. This sinigrin, $C_{10}H_{18}KNS_2O_{10}$, is decomposed under the influence of *myrosin*, an albuminous ferment which is present, and yields as products of decomposition C_3H_5CNS (allyl isosulphocyanate), $HKSO_4$ (acid potassium sulphate), and $C_6H_{12}O_6$ (glucose). "The aqueous solution of myrosin coagulates at 60° C. (140° F.), and then becomes inactive; hence mustard seed which has been heated to 100° C. (212° F.), or has been roasted, yields no volatile oil, nor does it yield any if powdered and introduced at once into boiling water." (*Pharmacographia*, p. 67.) As it is often adulterated with other oils, a test has been proposed consisting of concentrated sulphuric acid, 50 drops of which are to be mixed with 5 drops of the suspected oil in a small glass tube. If the oil be pure, little change of color will be produced, but if any adulterating oil be present, a red or brown color will soon appear. Rectified oil of petroleum is the only exception, as the color of this is not affected by the acid, but it would be recognized by its insolubility in sulphuric acid. (See *A. J. P.*, July, 1865, p. 285.) Adulteration with alcohol is readily detected by its much lower boiling point, which also enables it to be separated by distillation. It has been adulterated with considerable quantities of carbon disulphide, which may be detected by distillation at a temperature not exceeding 80° C. (176° F.) and mixing the distillate with sulphuric acid, when the carbon disulphide rises to the surface. Ammonia converts the mustard oil into *thiosinamin* (see Part II), according to the reaction which separates

$$CSNC_3H_5 + NH_3 = C_4H_8N_2S$$

in colorless rhombic crystals, melting at 70° C. (158° F.), and soluble in water, alcohol, and ether. The reaction is stated by Flückiger (*Pharm. Chem.*, 2d ed., 1888, p. 20) to be quantitative. Oil of mustard naturally contains about 0.56 per cent. of carbon disulphide. (*A. J. P.*, 1881, p. 572.)

White mustard seeds yield different products. When deprived of fatty oil they yield to boiling alcohol colorless crystals of *sinalbin*, an indifferent substance readily soluble in cold water, but sparingly so in cold alcohol. According to Will, it breaks up under the action of myrosin into *acrinyl sulphocyanate*, $C_7H_7O.CNS$, *sinapine sulphate*, $C_{16}H_{25}NSO_9$, and *glucose*, $C_6H_{12}O_6$. This acrinyl sulphocyanate is a nearly colorless, non-volatile oil, and the rubefacient and vesicating principle of white mustard. *Sinapine* has not yet been isolated, but it is an unstable alkaloid.

Uses.—Oil of mustard is a powerful rubefacient, although liable to blister unless used with much caution. Diluted, either with alcohol or lard, it is used as a counter-irritant application in *sprains, rheumatism* and like conditions. It may employed in strengths of from two to four per cent.

The volatile oil of mustard has been employed as a substitute for the mustard plaster. For this purpose one part may be mixed with sixty parts of alcohol, and the mixture sprinkled, not too thickly, on piline or muslin, covered with waxed paper. It acts speedily and efficiently.

The oil is too pungent and irritating to be given internally.

Off. Prep.—Linimentum Sinapis, *Br.;* Linimentum Sinapis Compositum, *N. F.;* Spiritus Sinapis, *N. F.*

OLEUM TEREBINTHINÆ. U. S.

OIL OF TURPENTINE Ol. Tereb. [Turpentine Oil "Spirits of Turpentine"]

(ō'lę-ŭm tĕr-ę-bĭn'thĭ-næ)

"The volatile oil distilled with water from the concrete oleoresin obtained from *Pinus palustris* Miller or from other species of *Pinus* (Fam. *Pinaceæ*). Preserve it in well-closed containers." *U. S.*

Essence de Térébenthine, *Fr. Cod.;* Huile volatile de Térébenthine, *Fr.;* Oleum Terebinthinæ, *P. G.;* Terpentinöl, *G.;* Essenza di trementina, *It.;* Esencia de trementina, Aceite volatil de trementina, *Sp.*

This oil is commonly called *spirits* (or *spirit*) *of turpentine*. It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water, but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it quite pure it should be redistilled from a solution of potassium hydroxide. The turpentine of *Pinus palustris* is said to yield about 17 per cent. of oil, while that from *Pinus Pinaster* affords 25 per cent., and that from *Pinus sylvestris* 32 per cent. Large quantities are distilled in North Carolina. The exportations of turpentine oil from the United States in 1913 amounted to 21,039,597 gallons, valued at $8,794,656; and in 1914, 18,900,704 gallons, valued at $8,095,958.

Pure oil of turpentine is "a colorless liquid having a characteristic odor and taste, both of which become stronger and less pleasant on aging or exposure to the air. Soluble in 5 volumes of alcohol. Specific gravity: 0.860 to 0.870 at 25° C. (77° F.). Optical rotation variable. Distil 200 mils of the Oil, at the rate of two drops per second, from a 300 mil globe flask, having the side tube 8 cm. above the bulb. Ninety per cent. of the Oil distils between 154° and 170° C. (309.2° and 338° F.), the temperature being read with the mercury column of the thermometer immersed in the vapor. Five mils

of the Oil, shaken with an equal volume of potassium hydroxide T.S., does not become darker than a light straw yellow after standing twenty-four hours. Five mils of the Oil, evaporated in a small dish on a water bath, leaves not more than 0.1 Gm. of residue. Three drops of the Oil, placed on unsized, white paper, and exposed to the air, evaporates entirely without leaving a permanent stain (*fixed oils*). Five mils of the Oil shaken vigorously with an equal volume of hydrochloric acid in a test tube, and allowed to stand for a few minutes, does not produce a brownish or greenish color. Into a flask of from 35 to 50 mils capacity, having a long graduated neck (cassia flask), and containing 25 mils of fuming sulphuric acid, introduce very slowly, *drop by drop,* with constant shaking 5 mils of Oil of Turpentine, keeping the temperature just below 65° C. (149° F.) by immersion in cold water during the addition of the oil, and for five minutes thereafter, in the meantime frequently agitating the mixture cautiously but vigorously. Then cool, and add sulphuric acid until the flask is filled to the upper graduation on the neck. The clear, reddish, viscous layer, which forms after the dark mass has settled for two hours, does not exceed 1 per cent. of the volume of Oil taken. A large layer of colorless liquid with a refractive index of less than 1.5 at 20° C. (68° F.) shows the presence of mineral oil.

"*Caution.*—The addition of the Oil of Turpentine to the fuming sulphuric acid, drop by drop, is necessary because of the violence of the reaction." *U. S.*

As found in commerce, it is always somewhat ozonized, but when perfectly pure it consists exclusively of carbon and hydrogen, and is composed of one or more *terpenes,* among which are pinene, which constitutes the major portion of the oil, and small amounts of camphene and fenchene with derivatives of pinene. (See p. 730.) The English or American oil (prepared from *Pinus australis*) is composed of *dextro-pinene,* while the French oil (prepared from *Pinus Pinaster*) is composed of *lævo-pinene.* On the other hand, the Russian turpentine contains, in addition to *pinene, dipentene* (or *cinene*) and *sylvestrene,* and the Swedish turpentine contains *pinene* and *sylvestrene.* Both the American and the French oil of turpentine boil at about 156° C. (312.8° F.). On heating oil of turpentine to about 300° C. (572° F.) in a sealed tube for several hours it is converted into a polymer called *iso-terebenthene,* $C_{20}H_{32}$, which is so oxidizable that it is converted into a viscid mass on exposure to the air for a few hours. It has, moreover, a marked odor, resembling oil of lemon, and boils at 176° to 177° C. (348.8°–350.6° F.). On treatment with a small portion of sulphuric acid, oil of turpentine yields an optically inactive liquid, which boils at 160° C. (320° F.). This is a mixture resolvable by repeated fractional distillation into *terebene,* $C_{10}H_{16}$, boiling at 150° C. (302° F.); *cymene,* $C_{10}H_{14}$, boiling at 175° C. (347° F.); a small quantity of a camphor-like body, boiling at 200° C. (392° F.); *colophene,* $C_{20}H_{32}$, boiling at 318° C. (604.4° F.), and a mixture of semisolid products of higher boiling point. Oil of turpentine absorbs hydrochloric acid gas, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor.* Both are mono-hydrochlorides, $C_{10}H_{16}.HCl$, but the latter is much more stable, and can be purified by crystallization from alcohol or ether. When turpentine oil is left in contact with concentrated hydrochloric acid a dihydrochloride is formed, $C_{10}H_{16}.2HCl$. This forms rhombic plates, insoluble in water, and decomposed by boiling with alcoholic potash, with formation of *terpinol* $(C_{10}H_{16})_2.H_2O$. (Allen, *Com. Org. Anal.,* vol. ii, p. 51.) Nitric acid converts oil of turpentine into resin, and by long boiling into *terebic acid,* $C_7H_{10}O_4$. Mixed with water and chlorinated lime, and then distilled, the oil yields a liquid which Chautard found to be identical with chloroform (*J. P. C.,* 3e sér., xxi, 88). Turpentine oil and other terpenes unite with water to form crystals of *terpin hydrate,* $C_{10}H_{18}(OH)_2.H_2O$, which sublimes often from turpentine oil which has long stood in contact with water and has then been heated to water bath temperature. These crystals are sometimes found in the natural oil also. The presence of alcohol with the water and turpentine oil facilitates their formation. Thus, a mixture of 1 part of nitric acid, 1 part of alcohol, and 4 parts of turpentine oil, spread out in flat dishes, will yield within a few days crystals amounting to 20 per cent. of the oil taken. If these crystals be fused at 116° C. (240.8° F.) they will lose water, and *terpin,* $C_{10}H_{18}(OH)_2$, will remain in crystalline needles, fusing at 104° C. (219.2° F.), and boiling at 258° C. (496.4° F.). If either of the hydrates just mentioned be boiled with sulphuric, phosphoric, or glacial acetic acid, *terpineol,* $C_{10}H_{17}OH$, will be formed along with hydrocarbons of the formula $C_{10}H_{16}$, such as *terpinene, terpinolene,* and *dipentene.* Terpineol is a thick, colorless, optically inactive liquid, with a pleasant hyacinthine odor and a bitter, feebly pungent taste. It is used extensively in perfumery. Baeyer (*Ber. d. Chem. Ges.,* xxvi, p. 826) has also prepared the methyl ether of terpineol. Oil of turpentine may be made to yield cymene identical with that existing in the oil of cumin and with that obtained by dehydrating camphor. (See *Cumin Seed,* in Part II; also see under *Olea Volatilia.*) Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. A small proportion of formic acid is said also to be generated. Hence the older pharmacopœias directed the oil to be rectified by distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapor, and its rapid formation, which causes the liquid to boil over. In

this country it is scarcely necessary, as the recent oil can be obtained at an expense less than that which would be incurred by redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the resinous portion. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water. (See *Oleum Terebinthinæ Rectificatum.*) For tests, see *Proc. A. Ph. A.*, 1893, 156.

C. T. Kingzett has shown that the atmospheric oxidation of turpentine is accompanied by the formation of a body having the formula $C_{10}H_{14}O_4$, which he regards as *camphoric peroxide*. This substance, by the action of water, is converted into hydrogen peroxide and camphoric acid. The disinfectant known as *"sanitas"* is produced by passing air through Russian oil of turpentine in contact with warm water. Berthelot has shown that oil of turpentine has, under certain conditions, the power, while undergoing oxidation itself, of causing the oxidation of other bodies, to which it imparts a portion of the oxygen absorbed from the air. All that is necessary to give this power to the oil is that soon after distillation it should be exposed to the air, as in a bottle half filled. Sunlight assists, but is not essential to, the change, which goes on even in the dark. The oil retains indefinitely the property thus acquired, but may be deprived of it by exposure to a boiling heat, or by agitation with reducing substances. No other chemical or physical change can be detected in the oil. (*J. P. C.*, May, 1860, 351.)

In this country the oil of turpentine is frequently adulterated with petroleum distillates. The adulteration is best detected by the treatment with sulphuric acid followed by steam distillation of the oil layer remaining above the sludge acid; this treatment with acid and after-distillation to be repeated if necessary. The sulphuric acid will thus completely polymerize the essential oil, leaving the paraffin hydrocarbons unaffected in the residual oily layer. A shorter and more readily executed test with sulphuric acid, though not so complete, is now given in the official test of the U. S. P. IX.

Considerable quantities of a turpentine obtained by steam distillation of the so-called "lightwood," or resin saturated stumps and pieces of pine wood, have been offered in recent years. For an experimental study of this process and an account of the product see an article by Walker, Wiggins and Smith. (*Chemical Engineer*, Dec., 1905, p. 78.)

The several species of pine indigenous to California and the slopes of the Sierra Nevada appear to yield quite different products. Wenzell (*A. J. P.*, March, 1872) described, under the name of *abietene*, an oil distilled from the exudation of the *Pinus sabiniana* (*Nut Pine* or *Digger Pine*). He found it to have a sp. gr. of 0.694, and to boil at 101° C. (213.8° F.). Sadtler (*A. J. P.*, April, 1879, p. 176) examined an oil of turpentine from California said to have been obtained from the *Pinus ponderosa* (*Heavy Pine*), and found it to agree substantially with Wenzell's abietene. It had a sp. gr. at 16.5° C. (62° F.) of 0.6974, boiled at 101° C. (213.8° F.), and was slightly lævogyrate. It gave negative results when treated with hydrochloric acid for the formation of a hydrochloride, did not form a hydrate, and was not acted upon by sulphuric acid or by nitrosyl chloride. These anomalous results were at once explained by the publication of a study of the abietene which had been made by Thorpe, who showed (*A. J. P.*, 1879, p. 293) that this exudation of the California pine is almost pure *heptane*, C_7H_{16}, one of the chief constituents of American petroleum. His results were also confirmed by Schorlemmer, who established the identity of the pine heptane with that from petroleum naphtha.

Uses.—The oil of turpentine is locally irritant and feebly antiseptic. It is absorbed through the mucous membrane of the alimentary canal and apparently also of the respiratory tract, and is eliminated partly with the breath to which it imparts its own odor, and through the urine to which it gives an odor resembling that of violets. After the ingestion of large doses it produces a sense of warmth in the stomach, accelerates the circulation, and causes a feeling of exhilaration associated with more or less vertigo and a sense of fullness in the head. These symptoms are attended frequently with nausea and frequently, although not always, succeeded by brisk catharsis. When given in small doses frequently repeated it at first stimulates the kidneys, augmenting the secretion of urine, but if the administration is continued too long it produces painful irritation of the urinary vessels amounting at times to violent strangury and may cause inflammation of the kidney with scanty, albuminous, or even bloody urine. In some constitutions it produces, even when taken internally, an erythematous eruption of the skin. Apparently enough may be absorbed after the inhalation of its vapor to irritate the urinary organs and it is stated that seamen of vessels loaded with turpentine sometimes develop strangury and hematuria.

Most of the therapeutic uses of the oil of turpentine may be attributed to its local irritant influence; thus during its elimination through the mucous membrane of the lungs it acts as a stimulant expectorant and is a useful remedy in *chronic bronchitis*. In the same way it acts as a stimulant to the kidney and is occasionally used as a diuretic, although this employment has largely passed out of vogue. As a carminative in *flatulent colic* it is one of the most valuable remedies we possess. It is sometimes of service for its local stimulant action for *chronic diarrheas* or *dysentery*. In *typhoid fever* it is useful not merely in tympanitic states for its carminative effects, but appears to have a direct influence upon the disease itself. According to the observations of Omelchenko (*B. G. T.*, 1891), while it is very feeble in its general antibacterial properties it has a special

toxicity for the typhoid bacillus and this organism will not grow in an atmosphere saturated with turpentine vapor.

Oil of turpentine has been used for many years in the treatment of *hemoptysis*. Of its mode of action we have no knowledge, but there is considerable clinical evidence as to its power to check bleeding; Smith (*B. M. J.*, 1908, i, p. 1218) has even recommended it in *purpura hemorrhagica*. Among other conditions in which it has been from time to time recommended with more or less reasonableness, are *helminthiasis, leucorrhea, chronic rheumatism, amenorrhea,* and *puerperal fever*.

For ordinary purposes the dose is from 5 to 10 minims (0.3–0.6 mil) repeated every two to six hours as may be necessary. As a remedy against the *tapeworm* the dose is from one-half to one fluidounce (15–30 mils), followed in half an hour by castor oil; the safety of these large doses is dependent upon the catharsis sweeping out the bowel before the turpentine can be absorbed. It is best administered in the form of an emulsion, although it is frequently given by dropping into a teaspoonful of sugar. The use of gelatin-coated capsules is not to be recommended because as soon as the gelatin dissolves in the stomach the undiluted oil comes in contact with the gastric mucosa and is liable to produce an undue degree of irritation. Lacambre gives the following process for making a pill of the oil. Take of oil of turpentine 8 grammes, white wax 20 grammes, powdered sugar 9 grammes, oil of lemon, 2 drops. Melt the wax in the oil of turpentine, pour into a mortar, allow to cool, then add the sugar and oil of lemon, and form a mass to be divided into pills of 0.2 or 0.25 Gm. (3 or 4 gr.) each. Roll them in powdered starch, and keep in a well-stoppered bottle. (*J. P. C.*, Sept., 1873, p. 223.)

In the form of an enema the oil of turpentine is highly useful in obstinate *constipation, tympanitis,* and *seat-worms*. From one-half to two fluidounces (15–60 mils) may be added to a pint of warm soapsuds.

Externally it is an excellent rubifacient and is widely employed in the form of liniments in various rheumatic affections as *lumbago, arthritis, neuralgias,* and the like. For this purpose it should be diluted with from one to three parts of cottonseed or other bland oil. In the form of turpentine stupe it is advantageously employed as a counter-irritant in various deep-seated inflammations, especially of the abdomen. The turpentine stupe is made as follows: a piece of flannel is wrung out in hot water and then dipped in previously warmed turpentine, quickly wrung out and applied to the part. It was also formerly employed as a local application to *burns* in which it was supposed to allay the pain and promote healing. For this purpose it was usually mixed with the rosin cerate so as to form a liniment capable of being spread upon linen (see *Linimentum Terebinthinæ*).

The following is the formula adopted many years ago by the Philadelphia College of Pharmacy for the rubefacient liniment known as *British Oil*, which is still in use in some parts of the country as a popular remedy. Oil of Turpentine, Linseed Oil, of each, 8 fl. oz., Oil of Amber, Oil of Juniper, of each, 4 fl. oz., Barbados Petroleum 3 fl. oz., Crude American Petroleum 1 fl. oz.

It has likewise been recommended as a local application in parasitic *skin diseases,* especially *pediculus capitis*. The inhalation of its vapors has been employed in *chronic bronchitis* and has been especially recommended by Skoda in *gangrene of the lungs*.

For internal use the rectified oil should be used. (See *Oleum Terebinthinæ Rectificatum.*)

Dose, five to ten minims (0.3–0.6 mil).

Off. Prep.—Linimentum Terebinthinæ, *U. S.;* Oleum Terebinthinæ Rectificatum, *U. S.;* Linimentum Opii Compositum, *N. F.;* Linimentum Terebinthinæ Aceticum, *N. F.;* Linimentum Tiglii Compositum, *N. F.;* Petroxolinum Sulphuratum Compositum, *N. F.*

OLEUM TEREBINTHINÆ RECTIFICATUM. U. S., Br.

RECTIFIED OIL OF TURPENTINE. Ol. Tereb. Rect. [Rectified Turpentine Oil]

(ō'lę-ŭm tĕr-ę-bĭn'thį-næ rĕc-tį-fį-cā'tŭm)

"Rectified Oil of Turpentine is the oil distilled from the oleo-resin (turpentine) obtained from various species of Pinus, and rectified." *Br.*

Essence de Térébenthine purifiée, *Fr.;* Oleum Terebinthinæ Rectificatum, *P. G.;* Gereinigtes Terpentinöl, *G.*

* "Oil of Turpentine, *a convenient quantity;* Solution of Sodium Hydroxide, *a sufficient quantity*. Shake the oil of turpentine thoroughly with an equal volume of solution of sodium hydroxide, and introduce the mixture into a still connected with a well-cooled condenser. Recover about three-fourths of the oil by distillation, separate the clear oil from the water, dry it by shaking with anhydrous calcium chloride, filter and preserve. Keep the product in well-stoppered, amber-colored bottles, in a cool place. Rectified Oil of Turpentine is to be dispensed when oil of turpentine is required for internal use." *U. S.*

When oil of turpentine is distilled in contact with sodium hydroxide solution, the distillate comes over purified and freed from the decomposition products which give the commercial oil the disagreeable odor and taste which are inseparable by ordinary distillation without alkali; hence this rectified oil is much preferable for internal administration. In the U. S. P. VIII and IX solution of sodium hydroxide was preferred to lime water, which was used in the U. S. P. 1890 to furnish an alkali to combine with resinous substances in commercial oil of turpentine. It has in other respects the same properties as Oleum Terebinthinæ. "Rectified Oil of Turpentine is a colorless liquid which conforms to the properties and tests under *Oleum Terebinthinæ,* specific gravity excepted.

Specific gravity: 0.856 to 0.865 at 25° C. (77° F.). Evaporate 5 mils of the Oil rapidly in a tared dish on a water bath; not more than 0.015 Gm. of residue remains. *U. S.*

"A colorless, limpid liquid. Characteristic odor; taste pungent, somewhat bitter. Specific gravity 0.860 to 0.870; *refractive index* at 25° C. (77° F.) 1.465 to 1.480. Distils almost entirely between 156° and 180° C. (312.8 and 356° F.), leaving no appreciable residue." *Br.*

For uses see p. 795.

Dose, five to ten minims (0.3–0.6 mil).

OLEUM THEOBROMATIS. U. S., Br.

OIL OF THEOBROMA Ol. Theobrom.
[Butter of Cacao, Cacao Butter]

(ō'lę-ŭm thē-ǫ-brō'mą-tĭs)

"A concrete fixed oil obtained from the roasted seeds of *Theobroma Cacao* Linné (Fam. *Sterculiaceæ*)." *U. S.* "Oil of Theobroma is a solid fat expressed from the seeds of Theobroma Cacao, *Linn.*" *Br.*

Oleum Theobromæ, *U. S.* 1880; Cocoa butter (improperly); Beurre de Cacao, *Fr. Cod.;* Oleum concretum e semine Theobromæ Cacao, *Fr.;* Oleum Cacao, *P. G.;* Kakaobutter, *G.;* Manteca de coco, Aceite de coco, *Sp.*

Theobroma Cacao Linn. is a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America. It is largely cultivated in all tropical countries, particularly in Guayaquil, Venezuela, Mexico, Trinidad, and the Philippines. The fruit is an oblong-ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cacao,* or *chocolate nuts,* of commerce. The cacao tree is usually cultivated in large estates, where it is grown in the shade of the banana or other large plant, and develops its pods from the stem continually, so that the harvest goes on all the time, although the product is greater in the spring and in the autumn. The pods are cut off, opened, and the beans contained in the glutinous sweet acid pulp are allowed to ferment, during which process the outer integument comes off easily. The beans are finally carefully dried, commonly in the sun, sometimes by means of a steam drying shed. If the sweating process is carried too far, or the beans during drying are wetted by rain, they blacken and are much lowered in value. These blackened beans are sometimes artificially whitened. Cacao beans have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odor. (See *Am. Drug.,* 1897, 311; also *Ph. Ztg.,* 1900, 756.)

The average of a number of analyses of raw nuts gave H. Weigmann (*König's Nahrungs- und Genussmittel,* 3d ed., vol. i, 1019) water, 7.93 per cent.; nitrogenous matter, 14.19 per cent.; theobromine, 1.49 per cent.; fatty matter (cacao butter), 45.57 per cent.; starch and other carbohydrates, 22.92 per cent.; crude fiber, 4.78 per cent.; pure ash, 3.99 per cent.; sand, 0.62 per cent. The coloring matter is probably the result of chemical change, as the fresh seeds are white. Theobromine has been found also in the shells in the proportion of about 1 per cent. (*A. J. P.,* 1862, 509.) The latter impart to boiling water a taste analogous to that of chocolate, but weaker, and are used for making a table beverage.

Theobromine was discovered by Woskresensky, who obtained it by the following method. The kernels are exhausted with water by means of the water bath; the solution is strained through linen, precipitated by lead acetate, and filtered; the filtered liquor is freed from lead by hydrogen sulphide, and evaporated; the brown residue is treated with boiling alcohol, and the liquor filtered while hot. Upon cooling, the theobromine is deposited in the form of a reddish-white powder, which is rendered colorless by repeated crystallization. Keller obtained it still purer by heating the powder between two watch glasses, by which a brilliant white sublimate was obtained. According to O. Donker and C. Treumann, theobromine is contained not only in the cotyledons but also in the shells of the cacao seeds. Four kilos of the latter yielded 13.5 Gm. of pure theobromine. Theobromine is now official. (See *Theobrominæ Sodio-Salicylas.*)

For Emminger's method of determining theobromine in cacao, see *P. J.,* 1896, 289.

Cocoa or *Prepared Cacao* is also official in the N. F. IV under the title *Cacao Præparata.* The description and tests are as follows:

"A powder prepared from the roasted, cured kernels of the ripe seeds of *Theobroma Cacao* Linné and of other species of *Theobroma* (Fam. *Sterculiaceæ*), deprived of a portion of its fat. A brownish powder having a chocolate-like odor and taste, free from sweetness. Extracted with cold water Cocoa yields not less than 14 per cent. nor more than 22 per cent. of soluble matter. Extracted with ether, Cocoa yields not less than 18 per cent. of fat, and the fatty residue does not have a spicy odor or taste. The residue, insoluble in ether, when examined under the microscope, shows not more than 3 per cent. of Cocoa shells, and no foreign starch granules or other foreign substances. Cocoa contains not more than 6 per cent. of crude fiber and not more than 12 per cent. of starch. Cocoa yields not less than 3.5 per cent. nor more than 8 per cent. of ash, which has a distinctly reddish color." *N. F.*

Cacao, usually but erroneously known as cocoa, is often sold in powder which is sometimes adulterated with various other ingredients such as ground rice, barley flour, sugar, etc. Mixed with hot milk or water it is much employed as a drink. It has the advantages over

tea and coffee that it is less stimulating to the nervous system and contains some nutriment. Chocolate is the solid substance expressed from the cacao bean after roasting. In Great Britain and the United States it is usually made, when pure, exclusively of the kernel of the cacao or chocolate nuts, which are first roasted, then deprived of their shells, and lastly reduced, by grinding between heated stones, to a paste, which is moulded into oblong cakes. Sometimes rice flour or other farinaceous substance, with foreign fats, is added, but these must be considered as adulterations. In the compounded form known as sweet chocolate, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added; vanilla is a favorite addition in America, France, and Spain. The well-known confection known as *"milk chocolate"* contains either whole or skim milk powder in addition to the foregoing ingredients. The U. S. Department of Agriculture standards for cocoa products are as follows:

"1. *Cocoa beans* are the seeds of the cacao tree, *Theobroma cacao,* L. 2. *Cocoa nibs, cracked cocoa,* is the roasted, broken cocoa bean freed from its shell or husk. 3. *Chocolate, plain chocolate, bitter chocolate, chocolate liquor, bitter chocolate coatings,* is the solid or plastic mass obtained by grinding cocoa nibs without the removal of fat or other constituents except the germ, and contains not more than three (3) per cent. of ash insoluble in water, three and fifty hundredths (3.50) per cent. of crude fiber, and nine (9) per cent. of starch, and not less than forty-five (45) per cent. of cocoa fat. 4. *Sweet chocolate, sweet chocolate coatings,* is chocolate mixed with sugar (sucrose), with or without the addition of cocoa butter, spices, or other flavorng materials, and contains in the sugar- and fat-free residue no higher percentage of either ash, fiber, or starch than is found in the sugar- and fat-free residue of chocolate. 5. *Cocoa, powdered cocoa,* is cocoa nibs, with or without the germ, deprived of a portion of its fat and finely pulverized, and contains percentages of ash, crude fiber, and starch corresponding to those in chocolate after correction for fat removed. 6. *Sweet cocoa, sweetened cocoa,* is cocoa mixed with sugar (sucrose), and contains not more than sixty (60) per cent. of sugar (sucrose), and in the sugar- and fat-free residue no higher percentage of either ash, crude fiber, or starch than is found in the sugar- and fat-free residue of chocolate."

Hagenbuch examined several commercial brands of chocolate, and found that the amount of fat or cacao butter present varied from 12 to 45.8 per cent. (*A. J. P.,* 1885, p. 276.) From this it would seem that manufacturers do not uniformly extract the fat from commercial chocolate.

Oil of Theobroma. Cacao Butter.—This is the fixed oil of the chocolate nut. It is extracted either by expression, decoction, or the action of a solvent. Soubeiran recommends that the seeds, previously ground, be mixed with one-tenth of their weight of water and then pressed between hot plates of tinned iron. It is advisable that the heat should not exceed that of boiling water, and even a lower heat will answer. When the method of decoction is used, the cacao should be slightly roasted before boiling. As a solvent, carbon disulphide has been found to answer well, as recommended in the preparation of the expressed oil of nutmeg. (See *Oleum Myristicæ.*) Upon the whole, the method of expression is perhaps preferable. The presence of water in the ground seeds is said greatly to facilitate the process. The expressed oil, now made largely in Philadelphia as a by-product in the manufacture of cocoa, occurs in the shape of oblong cakes, like those of chocolate, weighing about half a pound each. It is "a yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste. It is usually brittle at temperatures below 25° C. (77° F.). It is slightly soluble in alcohol, soluble in boiling dehydrated alcohol, and freely soluble in ether, chloroform or benzene. Specific gravity: about 0.973 at 25° C. (77° F.). It melts between 30° and 35° C. (86° and 95° F.). Dissolve 1 Gm. of Oil of Theobroma in 3 mils of ether in a test tube at a temperature of 17° C. (62.6° F.), and immerse the tube into water having the temperature of melting ice. The liquid does not become turbid nor deposit white flakes in less than three minutes; and if the mixture after congealing is again brought to 15° C. (59° F.), it gradually forms a perfectly clear liquid (*wax, stearin, or tallow*). Saponification value: not less than 188 nor more than 195 (see Part III, Test No. 9). Iodine value: not less than 33 nor more than 38 (see Part III, Test No. 8)." *U. S.*

"A yellowish-white solid, breaking with a smooth fracture. Odor resembling that of cocoa; taste bland, agreeable. Somewhat brittle at ordinary temperatures, but softening at 25° C. (77° F.). Specific gavity 0.990 to 0.998; melting point 30° to 33° C. (86°–91.4° F.); *saponification value* 188 to 195; *iodine value* 35.5 to 37.5; *acid value* not more than 2.0; *refractive index* at 40° C. (104° F.) 1.4565 to 1.4575. In ascertaining the melting point and specific gravity, seventy-two hours should be allowed to elapse between the time of melting and the time of determining the constants. When 1 gramme is dissolved at 17° C. (62.6° F.) in 3 millilitres of *ether* in a test-tube, and the tube placed in *water* at 0° C. (32° F.), the solution neither becomes turbid nor deposits a granular or flaky mass in less than three minutes; and if, after congealing, it is exposed to a temperature of 15.5° C. (60° F.), a clear solution is gradually formed (absence of certain other fats)." *Br.*

Cacao butter consists chiefly of the glycerides of stearic, palmitic, and lauric acids, and, further, of small quantities of the glycerides of arachidic, linolic, formic, acetic, and butyric acids. The percentage of stearic acid obtainable is from 39.9 to 40.6. Kingzett believes it to contain in addition a peculiar acid which he

calls *theobromic,* and to which he gives the formula $C_{64}H_{128}O_2$, but his results have not been confirmed by subsequent investigators. From its large proportion of stearin, it is one of the best fats for the preparation of stearic acid. It is said to be frequently adulterated with animal fats, which, according to E. Lamhofer, may be detected by attention to the fact that pure cacao butter dissolves entirely in ether or petroleum benzin, separating out in minute granular crystals when immersed in water of 0° C. (32° F.), the liquid portion remaining transparent for 30 or 40 minutes, when the whole solidifies. After solidification, if the oil be kept at a temperature of about 14.4° C. (58° F.), it will redissolve without turbidity. (*A. J. P.,* 1877, p. 238.) G. Ramsperger concludes, as the result of much experimentation, that ether affords the best test of purity (see the official tests).

Uses.—Butter of cacao is used as an ingredient in cosmetic ointments, and in pharmacy for coating pills and preparing suppositories. For the last purpose it is well adapted by its blandness, and the fact that although liquefying at a temperature below that of the body, it is of firm consistence at 21.1° C. (70° F.). It is also valuable for the reason that easily decomposable substances like silver nitrate, potassium permanganate, etc., may be incorporated in it without material change and it is therefore valuable as an excipient. It was chiefly on this account that it was introduced into the U. S. Pharmacopœia of 1860. It has the emollient properties of the fats and is used to soften and protect *chapped hands* or *lips.* F. Bringhurst prepared a *lip salve* by melting together 28 ounces of cacao butter, 4 ounces of yellow wax, and a drachm, each, of balsam of Peru and benzoic acid, straining, adding perfuming oils, as those of rose, bergamot, and bitter almond, in sufficient quantity, and finally, when nearly cool, an ounce of glycerin. (*A. J. P.,* July, 1867, p. 348.)

OLEUM THYMI. U. S.

OIL OF THYME Ol. Thymi [Thyme Oil]

(ō'lę-ŭm thī'mī)

"A volatile oil distilled from the flowering plant of *Thymus vulgaris* Linné (Fam. *Labiatæ*), and containing not less than 20 per cent., by volume, of phenols. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Huile volatile de Thym, *Fr. Cod.;* Essence de Thym, *Fr.;* Oleum Thymi, *P. G.;* Thymianöl, *G.;* Esencia de tomillo, *Sp.*

In the south of France thyme grows wild in great abundance, and is largely collected for distillation. The oil is taken from France to England, and thence reaches this country under the name of *oil of origanum,* having, probably from its greater cheapness, been substituted for the latter. (See Part II.)

Thymus vulgaris is a very common plant, indigenous to Southern Europe, and cultivated in our gardens. It possesses a subcampanulate two-lipped calyx, villous in the throat; corolla limb two-lipped, the upper erect and emarginate, the lower spreading, three-cleft. It is a low under-shrub, procumbent at the base, with ovate-linear, revolute leaves, the flowers occurring in a whorled spike. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odor, not lost by drying, and a pungent, aromatic, camphoraceous taste. Its active constituent is the volatile oil, which is obtained separate by distillation with water.

The oil, as prepared in Southern France, is, after one distillation, of a reddish-brown color, and called the *red oil,* but when again distilled is colorless, and in this condition is distinguished as the *white oil.* Oil of thyme is officially described as "a colorless or red liquid, having a characteristic odor and taste. It is soluble in 2 volumes of 80 per cent. alcohol. Specific gravity: 0.894 to 0.930 at 25° C. (77° F.). It is slightly lævorotatory. Shake 1 mil of the Oil with 10 mils of hot distilled water, and, after cooling, pass the aqueous layer through a wetted filter; the filtrate does not assume a blue or violet color upon the addition of a drop of ferric chloride T.S."

The U. S. Pharmacopœia introduced an assay based on the phenols content as follows:

"**Assay.**—Introduce 75 mils of sodium hydroxide T.S. into a flask with a long graduated neck (cassia flask), add 10 mils of the Oil to be assayed, stopper the flask tightly, shake the mixture thoroughly and set it aside for from twelve to twenty-four hours. Then add sufficient sodium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck of the flask, and, after the alkaline solution has become clear, adjust it to the temperature at which it was measured, and note the volume of the residual liquid. This measures not more than 8 mils, indicating the presence of not less than 20 per cent., by volume, of phenols." *U. S.*

According to Zeller, one pound of the fresh herb yields 45.7 grains of the oil, of the dried herb 38 grains. The oil, as found in commerce, is of a reddish-brown color, and of an odor recalling that of thyme, but less agreeable. Its specific gravity is stated at 0.905, but probably varies, as the oil is a complex body. The more volatile portion, that coming over below 180° C. (356° F.) in distillation, is a mixture of cymene, $C_{10}H_{14}$, boiling at 175° C. (347° F.), and pinene, $C_{10}H_{16}$, boiling at 161° C. (321.8° F.). The less volatile and most valuable portion is chiefly *thymol,* $C_{10}H_{14}O$, a white crystalline solid, melting at 50° C. (122° F.), and possessing a pungent taste. (See *Thymol.*) *Carvacrol* is also present, at times replacing part or all of the thymol, and in addition linalool and bornyl acetate have been found in small amount. (See *Proc. A. Ph. A.,* 1897, 637.)

The true oil of thyme, according to Bennett (*P. J.,* 1908, lxxx, p. 803), differs from the various oils known commercially under this

name, as well as the oils of origanum, in that it contains thymol, while the other oils of thyme contain the isomeric carvacrol. While it is probable that carvacrol has similar therapeutic properties to thymol, it has not been employed in medicine to any considerable extent and is far less well known.

The oil is commonly adulterated with the oil of turpentine, the *white oils* being especially impure. The presence of oil of turpentine, according to Duyk (*J. P. A.*, 1899, 41), is due to the fact that the French peasants place in the body of the still as a foundation for the herbs a layer of pine and fir branches.

The annual production of oil of thyme at Grasse, according to Flückiger (*A. J. P.*, 1885, 132), amounted to 40,000 kilogrammes.

Oil of thyme has been largely replaced in medicine by thymol. According to Camperdon, in doses of from three to fifteen grains (0.2–1.0 Gm.), oil of thyme causes mental excitement, and is a valuable diffusible stimulant in *collapse*. It is powerfully germicidal. (See *Thymol.*)

Dose, three to five minims (0.2–0.3 mil).

OLEUM TIGLII. U. S. (Br.)

CROTON OIL Ol. Tiglii

(ō'lę-ŭm tĭg'lĭ-ī)

"A fixed oil expressed from the seeds of *Croton Tiglium* Linné (Fam. *Euphorbiaceæ*). Preserve it in small, well-stoppered bottles, protected from light." *U. S.* "Croton Oil is the oil expressed from the seeds of Croton Tiglium, *Linn.*" *Br.*

Oleum Crotonis, *Br.*; Huile de Croton Tiglium, *Fr. Cod.*; Huile de Graines de Tilly, *Fr.*; Oleum Crotonis, *P. G.*; Krotonöl, *G.*; Olio di crotontiglio, *It.*; Aceite de croton tiglio, Aceite de grano tiglio, *Sp.*

Croton Tiglium Willd. is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark-green color on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf—the lower being female, the upper male—with straw-colored petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of India. It is pervaded by an acrid purgative principle, probably analogous to that found in other plants belonging to the family of *Euphorbiaceæ*. Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy, and, according to the same author, the leaves are so acrid that when chewed and swallowed they excite inflammation in the lips, mouth, and throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active part. These have been long used in India as a powerful purgative, and were employed so early as 1630 in Europe, under the names of *grana Molucca* and *grana tiglia*. But in consequence of their violent effects they fell into neglect, and had ceased to be ranked among medicines, when, at a comparatively recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for their oil, which is the only official product of the plant. It is probable that most if not all of the *Crotons* are purgatives. The oil of the Mexican *Croton morifolius* is said to be mildly purgative in doses of two or three minims (0.12–0.2 mil). In India, under the name of *Kowli seeds* (*Kuli seeds*), are used certain beans, which have been referred by authorities to the *Croton oblongifolius* Roxb., and also to the *C. persimilis* Müll.-Arg. (See *Ph. Rev.*, Oct., 1896.) Kowli seeds reach a length of 2.1 cm., a breadth of 1.2 cm., a thickness of 0.8 cm., ovate, having pointed ends with a marked caruncle. The outer side shows the grayish-brown crusty seed coat with irregular rough longitudinal stripes; the cross-section shows a large endosperm, in the middle the embryo of considerable size with flat cotyledons. Besides the fatty oil and protoplasm, the cells of the endosperm show longitudinally very large aleurone grains, which contain a considerable number of small globoids and badly formed crystalloids.

The seeds of the *C. Tiglium* resemble castor beans in size and general structure. They are oblong, rounded at the extremities, with two faces, the dorsal considerably more convex than the ventral, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes their ventral surface is flat, with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft, yellowish-brown epidermis, beneath which the surface is black and smooth, and, as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently mottled, and sometimes nearly black. The kernel or endosperm is yellowish-brown, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains (0.065 or 0.13 Gm.) the kernel purges severely.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, or carbon disulphide, which dissolves the oil and leaves it behind when evaporated. Guibourt recommends, after the first expression, to digest the residue with alco-

hol at a temperature of 48.8° to 60° C. (120°–140° F.), and then submit it to a new expression. The alcohol is to be separated by distillation from the oil, which is then to be mixed with the first product. Great care must be used, during this distillation, to prevent blistering the unprotected skin of the operator.

Extraction by Ether.—Having washed and dried the seeds, grind them in a coffee mill, and form a soft paste with ether. Introduce this into a narrow percolation tube, and gradually pour ether upon it until it is exhausted. Evaporate the ether by means of a water bath, and filter the remaining oil.

Extraction with Carbon Disulphide.—The seeds, well bruised, are introduced into a bottle with three times their weight of carbon disulphide, well rectified; the mixture is allowed to stand, with frequent agitation, for 24 hours; the whole is then poured upon a cloth and rapidly expressed. The residue is similarly treated with twice its weight of the disulphide, and expressed, after standing as before. The products of the two macerations are mixed, then filtered in a covered funnel, and finally submitted to distillation, by means of a water bath, in a glass retort, at the temperature of 71.1° or 76.6° C. (160° or 170° F.). The disulphide should be recovered by condensing its vapor in a refrigerated receiver. The oil is to be poured into a dish, to show that it contains none of the disulphide, and then introduced into a bottle and closely stoppered.

Properties.—The seeds consist of 64 per cent. of kernel and 36 of envelope. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 per cent. from the seeds. Croton oil consists chiefly of the glycerides of stearic, palmitic, myristic, lauric, and oleic acids. There are also present, in the form of glycerin ethers, the more volatile acids, as formic, acetic, isobutyric, and isovalerianic acids. The volatile part of the acid yielded by croton oil contains, moreover, an acid of the oleic series, named by Geuther and Frölich *tiglic* or *tiglinic acid,* $C_5H_8O_2$. It is isomeric with angelic acid, but the melting points (angelic acid 45° C. (113° F.), tiglic acid 64° C. (147.2° F.)) and the boiling points (angelic acid 185° C. (365° F.), tiglic acid 198.5° C. (389.3° F.)) differ. *Crotonic acid,* $C_4H_6O_2$, was thought by Schlippe to be present, but later investigation does not confirm the statement. *Crotonol,* announced by Schlippe as the vesicating principle of the oil, has likewise been found only by the discoverer.

In 1823 John Nimmo, of Glasgow, found that about 45 per cent. of croton oil is soluble in alcohol, the insoluble 55 per cent. being inert. Recent researches have shown that the percentage of soluble portion varies greatly. (See also below.) In this soluble portion Buchheim found an acid, *crotonolic acid* or *crotonoleic acid,* which he believed to be the active principle. It is an oily substance, readily decomposable, having the character of a weak acid, and forming various salts. It is freely soluble in alcohol, and is extremely irritant to the skin and the mucous membrane. As pointed out in 1889 by Stillmark and Kobert, croton seeds contain one or more toxic albuminoids, which have been especially studied under the name of *crotin* by Elfstrand. Dunstan and Boole (*Proc. Roy. Soc. London,* lxiii, 1895) found that crotonoleic acid, prepared by the method of Kobert and Hirscheydt, is a mixture of inactive oily acids and a resinous substance having extraordinary power as a vesicant, for which they have proposed the name of *croton resin,* assigning to it the empirical formula $C_{13}H_{18}O_4$, and the molecular formula $(C_{13}H_{18}O_4)_2$, or $C_{36}H_{36}O_8$. It is described as a hard, pale yellow resin, nearly insoluble in water, and benzene, but readily dissolved by alcohol, ether, and chloroform. It is neither a glyceride, a ketone, nor an aldehyde.

Crotonoleic acid may be readily prepared by treating the portion of croton oil soluble in alcohol with a hot saturated solution of baryta in a water bath, washing the stiff white paste that forms with cold distilled water to remove excess of baryta and barium compounds with acetic, butyric, and tiglic acids, repeatedly treating with water, and lastly agitating with ether, which takes up only the barium oleate and crotonoleate. The crotonoleate is separated by dissolving it out in alcohol, decomposing it carefully with sulphuric acid, and the solution containing the free acids carefully evaporated. (See also *Kobert's Arbeiten,* 1890, p. 30.)

Crotin is described as a yellowish powder, yielding about 21 per cent. of ash, soluble in water, and possessed of such active poisonous properties that the subcutaneous lethal dose for the rabbit is from 0.05 to 0.08 Gm. per kilo. It attacks the blood corpuscles as well as the centric nervous system, and, indeed, probably affects all protoplasm. (*On Some Toxic Albumins,* Upsala, 1897.)

Croton oil, as found in commerce, varies greatly in color, from a pale yellow to a dark reddish-brown. That imported from India is usually pale, that expressed in Europe dark, like the deepest-colored sherry. Its consistence is rather viscid, and is increased by time. Its odor is faint, but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. It is officially described as "a pale yellow or brownish-yellow, somewhat viscid and slightly fluorescent liquid, having a slight, characteristic odor. *Great caution is necessary in tasting it,* and it must be handled carefully as it causes a pustular eruption, when applied to the skin. It is slightly soluble in alcohol, the solubility increasing with age; freely soluble in ether, chloroform, or in fixed or volatile oils. It is acid to litmus paper previously moistened with alcohol. Specific gravity: 0.935 to 0.950 at 25° C. (77° F.). When gently heated with twice its volume of dehydrated alcohol, it forms a

clear solution from which the Croton Oil separates, either partially or completely on cooling. Add 1 mil each of fuming nitric acid and of distilled water to 2 mils of the Oil, and shake the mixture vigorously for a few minutes; it does not solidify either completely or partially after standing for twenty-four hours. Saponification value: not less than 200 nor more than 215 (see Part III, Test No. 9). Iodine value: not less than 104 nor more than 110 (see Part III, Test No. 8)." *U. S.*

"Brownish-yellow to dark reddish-brown; viscid, slightly fluorescent. Disagreeable odor; when cautiously tasted, acrid. Blisters the skin and mucous membrane. Specific gravity 0.940 to 0.960; *saponification value* 210 to 215; *iodine value* 102 to 106. Freely soluble in *ether* and in *chloroform*. Miscible with half its volume of *absolute alcohol*. Thickens slightly but does not solidify, either completely or partially, when vigorously shaken with half its volume of *fuming nitric acid* and the same proportion of *water* (absence of other non-drying oils)." *Br.*

The oil is wholly soluble in ether and oil of turpentine. Its relations to pure alcohol differ somewhat with the variety of the oil. That obtained by expression in England was formerly wholly and readily soluble, but, according to Harold Senier, the croton oil now produced acts towards alcohol as do foreign oils (*P. J.*, 3d ser., xiv, 704), forming a solution which is permanent at ordinary temperatures, while the India or pale oil forms an opaque mixture, which becomes clear and uniform upon being heated, but separates on standing into two portions, one consisting of alcohol somewhat diminished in bulk, the other of the oil correspondingly increased in bulk by retaining a portion of the alcohol. It is probable that the difference in color, and in their relations to alcohol, between the India and English oils may be owing to a change in the kernels from being kept, and to the age of the oil. According to Senier, confirmed by Binz, Kobert, and others, it increases with the age, freshly expressed oil containing only 20 per cent., oil over four years old 60 per cent. It is known that croton oil is often adulterated with other fixed oils, which having a different saponification and iodine number can usually be detected by those tests.

Croton oil may be detected when present in admixture with other oils by the following reaction: The sample of oil is shaken with twice its volume of dehydrated alcohol; the clear solution is superimposed upon a highly concentrated solution of potassium hydroxide in a test tube, which is then carefully warmed for thirty minutes on a water bath and then examined. If croton oil is present, an intense reddish-brown or reddish-violet ring forms at the junction of the two liquids. (*J. P. C.*, 1916, xiv, 38.)

For tests for croton oil, including iodine and acid numbers, see *Ph. Rev.*, 1897, 113.

According to M. Burrough, who was for some time in India, much of the oil there prepared is derived from the seeds of *Jatropha Curcas*, or *Curcas purgans*, the so-called *Barbados nuts*. This oil, though weaker than the genuine, was said by Burrough to be an efficient cathartic in the dose of three or four drops (0.15 or 0.2 mil). Hamilton states that croton seeds are afforded by *Croton pavana*, growing in Ava and Bengal, and probably a portion of the croton oil of commerce is obtained from these seeds. These facts may explain some of the discrepancies which have been observed in the effects of the oil.

Cash and Dilling (*J. P. Ex. T.*, 1914, v, p. 235) have also found a purgative oil in the seeds of the *Croton elliotianus* which grows in British East Africa.

Uses.—Croton oil is a powerful drastic purgative, in large doses apt to excite vomiting and severe griping pains, and capable, if immoderately taken, of producing fatal effects. It acts with great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in *mania, coma,* and the cases of children. A drop placed on the tongue of a comatose patient will generally operate. Though long used in India, and known for two centuries to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Conwell. It is chiefly employed in cases of *obstinate constipation,* in which it often produces the happiest effects after the failure of other medicines, but it may also be advantageously used in almost all cases in which powerful and speedy purging is demanded, especially where an irritation of the gastric mucous membrane and a derivative action are desired. The seeds are said to have been used successfully in India, in *amenorrhea.* Applied externally, the oil produces inflammation of the skin, attended with pustular eruption, and has been used as a counter-irritant in *rheumatism, gout, neuralgia, bronchitis* and other inflammations. It should be diluted with three parts of olive oil, soap liniment, oil of turpentine, or other convenient vehicle, and applied as a liniment twice or oftener in twenty-four hours. Sometimes the insusceptibility of the skin is such as to require its application undiluted. The oil may also be applied externally, in the form of a plaster, made by incorporating one part of it with four parts of lead plaster, melted by a very gentle heat. Sometimes it appears to produce inflammation in parts distant from those to which it was directly applied. It has been said that four drops, used externally by friction around the umbilicus, will produce a purgative effect, but this is denied by Barlai of Tuscany, who states that it is only when the oil is applied to the skin divested of the cuticle that it will operate upon the bowels.

Croton Oil Crayons.—In order to prevent the spreading of croton oil beyond the limits intended, Limousin prepared crayons by melting

1 part each of cacao butter and white wax in a small glass flask, and then adding 2 parts of croton oil, taking care to close the orifice of the flask at once with a cork. When the mixture begins to get thick, it is poured into cylindrical moulds, where it speedily solidifies. These crayons may be made of a thickness of about 8 or 9 millimeters (⅓ inch), and may be covered with tin foil to protect them from change. (*N. R.*, May, 1877.)

The oil is most conveniently administered in the form of pill. A safe and convenient plan is to make two drops into four pills with crumb of bread, and to give one every hour until they operate. The oil may also be given in emulsion.

Crotonoleic acid has been shown by Kobert to be a very active irritant poison, much more harsh and severe in its influence than croton oil itself. Hirscheydt has found that its salts injected into the blood are extremely powerful depressants to the circulation. It has appeared in commerce, but after trial has been found by Hirscheydt to act badly as a practical remedy. It probably also varies greatly in purity. Ten milligrammes were found by Hirscheydt to be very uncertain in their purgative effect, while large doses commonly produced excessive gastro-intestinal irritation. The superiority of croton oil over the acid probably depends upon the fact that the acid exists in it chiefly in combination with glycerin, and that this crotonoleic glyceride acts with comparative kindness because of the slow decomposition and setting free of the acid which occur in the intestines. This being the case, it follows as a corollary that old, acid croton oil must be more irritant than the fresher and nearly neutral oil. Kobert has confirmed this conclusion by actual trial, and asserts that the neutral oil should always be preferred in practice, and that the acid oil should be rejected.

Dose, one-half to two minims (0.03–0.12 mil).

OLIVERI CORTEX. Br.

OLIVER'S BARK [Black Sassafras]

(ŏ-lĭ'vẹ-rī cŏr'tĕx)

"Oliver's Bark is the dried bark of Cinnamomum Oliveri, *Bailey*." *Br.*

The genus *Cinnamomum* comprises some fifty-four species which are mostly tropical or subtropical evergreen shrubs or trees. They are mostly aromatic and comprise two principal groups: The one yielding camphor, and the other aromatic barks like cinnamon. Oliver's bark was official in the Ind. and Col. Add. for the Australian Colonies and is now official in the British Pharmacopœia. The tree which furnishes this bark is *Cinnamomum Oliveri* Bailey (Fam. *Lauraceæ*). It is indigenous to New South Wales and Queensland. It is much of the same habit as the trees yielding cinnamon and the bark is used as a substitute for this spice in the Australian Colonies.

"In flat pieces usually about twenty centimetres long, four centimetres wide and one centimetre thick. Cork greyish-brown, very warty. Inner surface umber-brown, satiny. Fracture short, slightly fibrous. In transverse section, umber-brown, a pale line separating the cork from the inner tissues. Aromatic odor; taste aromatic, bitter, camphoraceous." *Br.*

Off. Prep.—Tinctura Oliveri Corticis, *Br.*

OPII PULVIS. U. S.

POWDERED OPIUM Opii Pulv. [Opii pulvis, P. I.]

(ō'pĭ-ī pŭl'vĭs)

"Opium dried at a temperature not exceeding 70° C. (158° F.), reduced to a very fine powder, and yielding not less than 10 per cent. nor more than 10.5 per cent. of anhydrous morphine. Powdered Opium of a higher morphine percentage may be brought within the required limits by admixture with powdered opium of a lower percentage, or with some inert diluent. Preserve it in well-closed containers." *U. S.*

Poudre d'Opium, *Fr. Cod.;* Opiumpulver, *G.;* Polvo de opio, *Sp.*

"Powdered Opium is light brown; consisting chiefly of yellowish-brown to brownish-red, more or less irregular and granular fragments, varying from 0.015 to 0.15 mm. in diameter; a few fragments of strongly lignified, thick-walled, 4- to 5-sided or narrowly elongated, epidermal cells of the poppy capsule; and very few fragments of tissues of poppy leaves, poppy capsules, and rumex fruits.

"Assay.—Proceed as directed under *Opium*." *U. S.*

The strength of powdered opium has been altered in the last revision. The U. S. P. VIII required that it should yield not less than 12 per cent. nor more than 12.5 per cent. of *crystallized* morphine, but it will be observed that the figures have been lowered, and the assay process based upon an anhydrous instead of a crystallized morphine. The preparation is thus made to conform to the International Protocol standard. For assay and preparations see pp. 817 and 822, respectively.

The German Pharmacopœia requires that the strength be adjusted to 10 per cent. of morphine by the use of rice starch. Ground cacao shells and powdered sugar of milk are commonly used as diluents for adjusting the strength of powdered opium.

Dose, one-half to one grain (0.032–0.065 Gm.).

OPIUM. U. S., Br.

OPIUM

(ō'pĭ-ŭm)

"The air-dried, milky exudation obtained by incising the unripe capsules of *Papaver somniferum* Linné and its variety *album* De Candolle (Fam. *Papaveraceæ*), and yielding, in its

normal, moist condition, not less than 9.5 per cent. of anhydrous morphine." *U. S.* "Opium is the juice obtained by incision from the unripe capsules of Papaver somniferum, *Linn.*, inspissated by spontaneous evaporation. Any suitable variety of opium may be employed as a source of Tincture of Opium and Extract of Opium, provided that when dry it contains not less than 7.5 per cent. of anhydrous morphine; but, when used for official purposes other than the preparation of the alkaloids or their salts, opium must be of such a strength that when dried, and powdered, the resulting powder dried at 60° C. (140° F.) yields not less than 9.5 per cent., and not more than 10.5 per cent., of anhydrous morphine. Opium yielding when dried more than 10 per cent. of anhydrous morphine must be diluted to that percentage either with powdered Milk Sugar or with any opium containing when dried between 7.5 and 10 per cent. of anhydrous morphine." *Br.*

Lachryma Papaveris, Meconium, Succus Thebaicus, Thebaica; Opium, *Fr. Ged.*; Opium, *P. G.*; Mohnsaft, *G.*; Oppio, *It.*; Opio, *Sp.*; Affioni, *Turk.*; Ufyoon, *Arab.*; Sheerikhaskash, *Pers.*; Ufeem, *Hindost.*

Opium is generally believed to be derived exclusively from *Papaver somniferum,* though every species of poppy is capable of yielding it to a greater or less extent, and some authors assert that *Papaver orientale* is its real source. The United States, British, and French Pharmacopœias recognize only the first-mentioned species and its varieties.

Papaver somniferum, or *Opium Poppy.*—There are several varieties of this species, of which the two most prominent are distinguished by the titles of the white and the black poppy, derived from the color of their seeds. It is the former (var. *P. album* DC.) which is usually described as the proper opium plant. The *white poppy* is annual, with a roundish, smooth, erect, glaucous, often branching stem, usually rising two or three feet in height, but sometimes five or even six feet in favorable situations. The leaves are large, variously lobed and toothed, and alternately disposed on the stem, which they closely embrace. The flowers are terminal, very large, and of a white or silver-gray color. In India they appear in February, in Europe and the United States not earlier than June, July, or August. The calyx is smooth and composed of two leaves, which fall when the petals expand. These are usually four in number, but there is a variety in which the flower is double. The ovary is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, rounded, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigmas, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which when perfectly ripe escape through small openings beneath the stigma. In the *black poppy,* the flower, though sometimes white, is usually violet-colored or red, the capsule somewhat smaller and more globular, and the seeds of a brown or blackish color.

There is a third variety, *Papaver somniferum setigerum* DC., which, however, is not cultivated as a source of opium.

All parts of the poppy contain a white, opaque, narcotic juice, but the leaves, analyzed by Blondeau, yielded none of the active principles by which opium is characterized. (*J. P. C.*, vii, 214.) It is in the capsule that the juice most abounds and the virtues of the plant chiefly reside, hence this part is sometimes employed medicinally and was official in the British Pharmacopœia of 1898 (*Papaveris Capsulæ*). The dried poppy capsules vary in size from 5 to 7.5 cm. in diameter, and in shape from ovoid to globular, according to the variety of the poppy from which they are procured. Those commonly found in commerce are spheroidal, flattened below, and surrounded by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above the surface and appear to be prolongations of partial septa or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. They are of a dirty white or purplish brown color, of a consistency somewhat like that of paper, inodorous and with little taste unless long chewed when they are decidedly bitter. They contain the same principles as opium but in much smaller amounts. The seeds are destitute of narcotic properties, and are even used as food. The Romans employed them in the preparation of various dainties. They are commercially known as *maw seed* (probably a corruption of the German *mohnsamen*) and frequently used for culinary purposes, they abound with a bland oil, called commercially *poppy seed oil,* or maw oil, which may be extracted by expression. The latter is of a straw-yellow color, without odor, and of a pleasant almond taste. It is without narcotic properties, and much resembles olive oil, as a substitute for which and an adulterant of which it is very largely used on the continent of Europe. It has a low congealing point, thickening only at –15° C. (5° F.) and solidifying at –20° C. (–4° F.). The black variety is specially used for the expression of oil, as its culture is easier, and the oil percentage in both varieties is practically the same, ranging between 50 and 60 per cent. As the oil cake generally retains about 8 per cent. of the oil, the yield by expression is from 42 to 50 per cent. Poppy oil contains the glycerides of stearic and palmitic acids, together with those of linolic, linolenic, and oleic acids. Of the liquid fatty acids, linolic constitutes about 65 per cent., oleic 30 per cent., and linolenic 5 per cent. Myristic and lauric acid seem to be absent. The oil is an article of much importance on the continent of Europe, particularly in France and Germany, where it is employed for culinary and pharmaceutical purposes, in painting and the manufacture of soap, and in other ways, as a substitute for olive oil. The poppy does

not appear to elaborate the milky fluid in which its narcotic properties reside before a certain period of its growth, for we are told that, in Persia, the young plants which are pulled up to prevent too thick a crop, are used as potherbs, and the μήκων of the Greeks, which is believed to be identical with the *Papaver somniferum*, is said by Hippocrates to have been nutritive.

Though generally believed to be a native of Asia Minor, this species of poppy grows wild in the south of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, Egypt, China, Japan and Asiatic Turkey, for opium, and in certain parts of Europe chiefly for its seeds. Attempts have been made both in Europe and the United States to produce opium from the poppy, but although it is possible to obtain the product, commercial success has not been and probably never will be achieved in America because of the cost of labor. A very good quality of opium is said to have been produced in Australia. (See *Australian Journal of Pharmacy*, Nov., 1887.)

The British Parliament has condemned the opium traffic and the Chinese Government has provided for the suppression of the use of opium. While there is no doubt that the people of China even more than the Government recognize in opium a deadly national evil and have resolved upon its extirpation, yet the statistics do not show any great reduction of the cultivation of opium in China.

Various attempts have been made in England to cultivate the poppy, all of which have resulted in commercial failure. (For particulars, see Seventeenth edition, *U. S. D.;* also *Edinb. Phil. Journ.*, i, 258.) The same may be said of the attempts to cultivate opium in France, which have apparently ceased since the death of Aubergier, who devoted much time and money to the subject. (For particulars, see 15th ed., *U. S. D.;* also *P. J.*, xv, 693.)

In 1865, Robertson, of Campbell Co., Virginia, produced opium which yielded to the analysis of I. J. Grahame 4 per cent. of morphine, besides narcotine. (*A. J. P.*, 1867, p. 50.) H. Black, of Bolivar, Tennessee, produced an opium from which E. S. Wayne obtained 10.2 per cent. of morphine. (*Ibid.*, Jan., 1868.) Very fine opium has been produced by J. H. Flint, of California (*A. J. P.*, 1874, p. 105); also in Minnesota, by E. Weschke (*Contributions Dep. Pharm. University of Wisconsin*, 1886), but in the opinion both of Flint and of Weschke, the high price of labor forbids the profitable production of opium in the United States. For an account of North Carolina opium, see *Proc. A. Ph. A.*, 1894, 286; also *A. J. P.*, 1896, 435; also *Proc. A. Ph. A.*, 1904, 438. True reports on some experiments in the cultivation of opium poppy in the United States and states that it yields a good crop in Vermont, and a bumper crop in the dry climate of the state of Washington. (*Proc. N. W. D. A.*, 1911, p. 17.) He also outlines a plan for converting the waste product of the poppy seed industry, the capsule, into a valuable source of opium alkaloids. (*Oil, Paint, and Drug Rep.*, 1906, lxx, p. 37.)

Considerable interest is being manifested in the cultivation of opium throughout the world. Thoms reports on the cultivation of opium poppy and the production of opium at Dahlen, near Berlin. His article not only includes his own experiments, but contains an excellent summary of the work done elsewhere. (*Ber. d. Pharm. Ges.*, xvii, p. 24.) Mitlacher gives the results of his experiments in the cultivation of *Papaver somniferum* and *P. Rhoeas* in *Zeit. Oest. Apoth.*, l, p. 431. (See also *Sudd. Apoth. Zeit.*, liv, p. 239; and *Ph. Zentralh.*, lv, p. 110.) The following articles are of interest in this connection: Stahl "On Persian Opium" (*Chem. Zeit.*, xxxii, p. 804); van Itallie and Kerbosch "On Opium in Northern China" (*Arch. Pharm.*, 1910, p. 614); "Opium Cultivation in Turkey" (*C. D.*, lxxxiii, p. 134); "On the Cultivation of Opium at Dorpat" (Muszynski in *Apoth. Zeit.*, xxvi, p. 431).

The opinion that a hot climate is not necessary for the production of the narcotic principles has the support of Guibourt (*J. P. C.*, Sept., 1867, p. 222), and would seem to be established by the facts that the opium of Anatolia is richer in morphine than that of the much hotter regions of Bengal and Upper Egypt, and that good quality of opium is produced in the northern United States as well as in France and Germany.

Opium is obtained from the capsule of the poppy in a manner almost the same as that described by Dioscorides eighteen hundred years ago. A few days after the petals have fallen from the flower, when the capsule is approaching maturity, horizontal incisions into the capsule are made, usually with a several-bladed knife, care being taken not to penetrate the cavity. The white juice which exudes is allowed to harden for twenty-four hours, when it is scraped off by means of a large, blunt knife, a portion of the epidermis of the capsule being removed and constituting about six to ten per cent. of the product. In some places the poppy-head yields opium but once, but in Persia and probably other very hot countries the operation is repeated two or three times after periods of rest. The quality of the product depends largely upon the weather; if this is very hot and dry, the juice will be scanty and very thick, but if the weather is moist the product will be larger but more aqueous. After gathering, the poppy juice is worked up into opium in a manner which differs in different producing countries. An opium-like substance has been in past times, and perhaps even is at present in some districts, produced by making an aqueous extract from the nearly ripe capsule of the poppy. Accord-

ing to the writings of Dioscorides the ancient Greeks were acquainted with both processes of producing the drug from the poppy capsule. The term *ὀπίον*, derived from *ὀπος, juice,* they applied to the substance procured by incisions, which answers precisely to the modern opium. The inspissated expressed juice they called *μηκωνιον*, from *μήκων*, the name of the plant.

Commercial History.—Commerce is supplied with opium chiefly from Asia Minor, China, India, Persia and Egypt. The Smyrna or Asiatic opium constitute the principal commercial article, the total annual output being nearly 1,000,000 pounds. Of this it has been variously estimated that from one-third to two-thirds is shipped to the United States, the latter country being the greatest consumer of opium of any country in the world. (*C. D.,* lxxix, p. 384; *Oil, Paint, and Drug Rep.,* lxxx, p. 7.) The importations in 1914 were 441,621 pounds of crude and 32,105 pounds of powdered opium; in 1915, 353,006 pounds of crude and 38,977 pounds of powdered opium.

The commercial opiums may be classified into the following varieties: (1) Levant or Turkey opium, including Asia Minor or Smyrna opium; (2) Persian opium; (3) Egyptian opium; (4) East Indian and China opium; (5) Grecian opium; (6) Bulgarian and Macedonian opium; (7) German opium; (8) French opium; and (9) Australian opium.

Turkey Opium.—This title belongs to the opium produced in the Turkish province of Anatolia, and exported from Smyrna and Constantinople. According to some authorities, there is no essential difference between the parcels of the drug brought from these two ports. Others maintain that they are distinct varieties, differing in their interior structure, and probably also in the precise place of their production and the mode of their collection. The truth probably is that most of the opium shipped at Constantinople is produced in the more northern parts of the opium districts of Anatolia, while that from Smyrna is collected in the provinces more convenient to the latter city, and, although it is possible that an identical drug may often be brought from the two ports, yet there are grounds for arranging it under different varieties, as derived from these different sources. There can be little doubt also that a portion of opium which is taken to Constantinople is produced in Macedonia in Europe, which must, therefore, be added to the opium producing regions.

Smyrna Opium.—This is the variety which is, beyond all comparison, most abundant in our markets, and it is from this that the ordinary descriptions of opium are drawn up. It comes to us in masses of various size, usually from half a pound or somewhat less, to a pound in weight, sometimes, though rarely, as much as two or even three pounds; originally, perhaps, of a globular form, but variously indented, and rendered quite irregular in shape by the pressure to which they have been subjected, while yet soft, in the cases which contain them. Sometimes they are even pressed out into flat cakes. As brought into market, the lumps are usually hard on the outside, but still soft within. They are covered externally with the remains of leaves, and with the reddish fruits of a species of *Rumex,* which have no doubt been applied in order to prevent the surfaces from adhering. Notwithstanding, however, this coating, the masses sometimes stick together, and two or more become consolidated into one. In this way the fact may be accounted for, that the seeds of the *Rumex* are occasionally found in the interior of the masses. In the finer parcels of Smyrna opium the color internally is light brown; in the inferior it is darker. A peculiar character of this variety is that, when a lump of it is cut into and then carefully torn, numerous minute shining tears are observable, particularly under a microscope, bearing some resemblance to small seeds, but readily distinguishable by pressure between the fingers. They are undoubtedly formed from the drops of juice which escape from the incisions in the capsules, and which, according to Bélon, are allowed to concrete before they are removed. From the account of the same author it appears that after the juice has been collected it is not subjected to the process of kneading or beating, as in the case of other varieties of the opium; so that the tears preserve their original shape in the mass. It is probably owing to the peculiar mode of collecting Smyrna opium, that minute pieces of the epidermis of the poppy capsules are found intermingled in the mass, these being separated in the process of removing the adhering tears. In the best specimens of Smyrna opium, these fragments of the capsules are the only impurities. This variety of the drug is of very different qualities, the finest kinds yielding, according to Merck, as much as 13 per cent. of pure morphine, while from some very bad parcels he could not procure more than 3 or 4 per cent. In these inferior specimens the color is darker, the odor is often musty, and there is very generally more or less mouldiness both upon the surface and in the interior of the masses, indicating perhaps too much moisture in the opium originally, or its subsequent exposure to an injurious degree of dampness. Good Smyrna opium ought to yield 10 to 11 per cent. of morphine. Christison, however, states that he has not been able to procure more than 9 per cent. from the finest Smyrna opium. According to Landerer, little of the opium is produced in the immediate neighborhood of Smyrna, the greater portion being brought, on the backs of camels, from a distance of from ten to eighteen days' journey. (*J. P. C.,* 3e sér., xxiii, 33.) The same writer states that the opium is chiefly prepared at Kara-Hissar, near Magnesia. The incisions are generally made before sunrise. The juice is partly caught in mussel-shells, and dried in the sun. This is considered the best. Every evening the juice which has dried upon the capsules is scraped off, with a portion of the epidermis. The poppy plant is then cut down,

and stripped of its leaves, which are boiled in water, and the liquor is evaporated to the consistence of an extract. With this the inspissated juice is incorporated, and the mixture is then formed into cakes, wrapped in poppy leaves, and placed on shelves to dry. (See *A. J. P.*, xxiii, 251.) It is very evident, from the interior structure of the *best Smyrna opium*, that it has not been prepared in the way described by Landerer, though his account is probably true in reference to inferior varieties.

Constantinople Opium.—Most of the Constantinople opium is in flattened lumps from half a pound to two and a half pounds in weight, and scarcely distinguishable in exterior appearance from those of the former variety, being equally irregular in shape, and in like manner covered with the fruits of the *Rumex*. According to Merck, however, it often differs strikingly from the Smyrna opium in its interior constitution, being wholly destitute of the tears which characterize that variety. This would indicate some difference in the mode of collecting and preparing the juice. In the case of the Constantinople opium it is probably removed from the capsules before concretion. Merck says that he has not discovered in this variety those minute portions of the poppy capsules which are usually present in Smyrna opium. The average quality of the Constantinople opium, as above described, is about equal to that of the drug from Smyrna, but it appears to be occasionally purer, as Merck obtained from one specimen as much as 15 per cent. of pure morphine. R. Bauer, of Constantinople, in 1867 denied that any of the varieties produced near Smyrna contain tears, except the single one from Magnesia. (*N. R. Pharm.*, xvi, 751.)

In an account, by Bourlier, of the culture of the poppy and collection of opium in Bithynia, a province of Asia Minor, near Constantinople, it is stated that the lumps, when formed out of the concrete juice, are enveloped in poppy leaves, and no mention is made of the use of the Rumex fruits to prevent adhesion. It is the opium here collected which, according to Bourlier, is known throughout the Levant and in Europe as Constantinople opium. The same authority states that the yolk of egg is sometimes largely used for adulterating opium—a fraud which may be detected by the large proportion of fatty matter which the adulterated drug yields to ether, and by the impossibility of drying it so as to fit it for pulverization. (*Ann. Thér.*, 1859, p. 4.) See also Guibourt (*Ann. Pharm.*, xxiv, p. 65; and *U. S. D.*, 19th ed.).

Egyptian Opium.—Much opium was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection, hence the term *Opium Thebaicum*, and the old name of laudanum, *Tinctura Thebaica*. This variety occurred in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes were either wrapped in a poppy leaf, so placed that the mid-rib divided the surface into two equal parts, or exhibited vestiges of such a covering. Occasionally the brown color of the opium was seen through the leaf, and the surface appeared as if uncovered, while the leaf was still present. The fracture was conchoidal and of a waxy luster and small fragments of it were translucent. Its color was usually redder than that of Smyrna opium, though sometimes dark. Some of the pieces, on exposure to the air, became damp and sticky on the surface, indicating the fraudulent addition of a deliquescent substance. The odor was similar to that of Smyrna opium, but weaker. It was an inferior variety, as the best of it, examined by Merck, yielded only 6 or 7 per cent. of morphine, and a specimen of it was found by J. Evans, of Philadelphia, to contain not more than 3.55 per cent.

India Opium.—The opium of Hindostan is distributed extensively through continental and insular India, where it is habitually employed as a narcotic-stimulant. Great quantities were also sent to China, into which it found an easy entrance, notwithstanding prohibitory laws. Much was formerly imported by the East India Company into England, through which a small proportion reached our own country. For various reasons India opium no longer enters Western commerce to any extent. It is not suitable for medicinal purposes.

There appear to be two chief varieties of it—one produced in Bahar and Benares, in the Bengal Presidency, and called *Bengal opium*, the other in the interior provinces, and designated by the name of *Malwa opium*. For minute description of Indian opium, see *P. J.*, xi, xii, abstracted *A. J. P.*, xxiv, 118; also *Pharmacographia*.

Bengal Opium, Benares Opium, Patna Opium.—This is produced in Hindostan chiefly under government supervision. The drug as first obtained is semiliquid, owing to the excessive dews, but is allowed to drain and dry by spontaneous evaporation until only 30 per cent. of moisture is left, when it is taken to the government factories. Great care is exercised to prevent adulteration. In the factories it is worked up with the drainings (known as *passewā*), poppy petals, and ground poppy plant into balls of standard strength. These are called "*cakes*," are about six inches in diameter, and are prevented from adhering by being rolled in the ground poppy plant. It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy petals. The interior of the mass is of a brownish-black color, of the consistence of a stiff paste, and possessed in a high degree of the characteristic odor and taste of opium. The analyses of India opium vary decidedly in their results; Eatwell, 2.17 to 3.67 per cent. of morphine, 3.85 to 5.70 per cent. of narcotine; Procter (Patna opium), morphine, 5 per cent.; Flückiger and Hanbury (Khandesh opium), morphine, 6.07 per cent. (Patna

opium), morphine, 8.6 per cent., narcotine, 4 per cent.; Solly (Khandesh opium), morphine, 7 per cent.; Watson (a number of varieties), 3.5 to 6.1 per cent. of morphine. (*P. J.*, xi, 362; *A. J. P.*, xxi, 194; *Pharmacographia*, 2d ed., p. 61.) India opium is, therefore, much inferior to the best Smyrna opium in its yield of morphine, while it is richer in narcotine. Its inferior character is possibly, in some degree, owing to the circumstance that the juice, after collection, is kept for some time before it is made up, and consequently undergoes fermentation. (See *P. J.*, 1895, 208; *Ph. Centralh.*, 1895, 589; also *C. D.*, 1896, 134.)

Malwa Opium.—Malwa opium is a variety not made in Hindostan proper nor under government supervision. Its quality varies greatly. It sometimes occurs in flat, roundish cakes, five or six inches in diameter, and from four to eight ounces in weight. In other instances it is in rectangular masses called bricks, or even in roundish balls. It seems never to be encased in poppy remnants. The masses are commonly quite hard, dry, and brittle, of a light-brown color, a shining fracture, a compact homogeneous texture, and free from mechanical impurities. A specimen of Malwa Opium described by Carson (*A. J. P.*, xxi, 195) broke with a rough fracture, which was of a blackish-brown color, here and there showing irregular oily spots. Procter obtained from it 9¼ per cent. of morphine. For other varieties of Indian opium, see *U. S. D.*, 19th ed., p. 892.

Persian Opium.—This variety of opium is distinguished from the Turkey gum in having a uniform non-granular consistence. It has been produced in Persia for a great many years, but about 1870 a great stimulus seems to have been given to the cultivation of the poppy and to the improvement of the product. At that time it was described as follows: Sometimes it is in cylindrical pieces, about three and a half inches long and half an inch thick, wrapped in glossy paper, tied with a cotton thread, and each weighing about half an ounce; more frequently it is in short rounded cones weighing from 6 to 10 ounces; it also occurs in flat circular cakes. It has the liver-brown color of Egyptian opium, a virose musty odor, and a very bitter taste, and, like Egyptian opium, softens in a moist atmosphere. The character of the opium has undoubtedly changed of late years. The most important local varieties of Persian opium appear to be the so-called *Mesched opium*, which occurs in grayish-brown shining sticks, wrapped in paper, and *Ispahan opium*, of similar appearance, but of a purer brown color. According to the investigations of Schindelmeiser (*Ap. Ztg.*, 1904, 19) the Mesched opium, when freed from moisture, yields from 5.9 to 8.7 per cent. of morphine; while Ispahan opium has in it from 11.9 to 19 per cent. of the alkaloid. *Tschakida* of the Persians is a dark brown, blackish impure opium occurring in cakes prepared for smoking, and according to Schindelmeiser contains not more than 0.4 per cent. of morphine. Schindelmeiser states that Caucasian opium is largely adulterated with inspissated fruit juices, and frequently contains less than 2 per cent. of morphine.

According to Seidler, in 1903 the making of opium in Persia was flourishing, amounting to 3000 chests, each containing 60 kilogrammes, a year, but the drug is chiefly consumed in Persia by the opium smokers, and of that which was exported in 1903, 90 per cent. is said to have gone to Hong Kong and 10 per cent. to London and Egypt; so that very little of the Persian opium finds its way into the European market, and the last of its importation into the United States of which we have knowledge was in 1902. According to Seidler, Persian opium now occurs in two forms, one in irregular masses with rugous irregularly fissured surface; the other in elongated squarish rods or masses, 0.7 to 1 centimeter in thickness, with a smooth surface and fracture. W. D. Howard examined a sample of the Persian opium sent to England as "perfectly pure," which yielded to him on analysis, without previous drying—morphine, 10.40 per cent.; codeine, anhydrous, 0.29 per cent.; narcotine, 2.50 per cent.; thebaine, 0.57 per cent.; cryptopine, 0.09 per cent.; papaverine, a trace. He is unable to say whether it contained any narceine. Rosengarten and Sons (now Powers-Weightman-Rosengarten Company), of Philadelphia, formerly used large quantities of the Persian opium in the production of morphine, obtaining from it an average of 10 per cent. of that alkaloid. In their more recent analyses the drug has yielded from 10 to 12.8 per cent. of actual morphine, the codeine in percentage varying very greatly apparently with the crop of the year; in some years the opium contained no codeine, in others 0.6 per cent.; commonly the percentage varies from 0.3 to 0.4 per cent.

Between 1910 and 1915 there were occasional importations into the United States of a high assaying granulated form of opium, which ranged in morphine content from 20 to 23 per cent., an amount greater than is present even in official extract of opium. It required special modification of the ordinary methods of assay to allow for the abnormal amount of active principle present.

"Boston opium," so called, was a sophisticated article.

The table below exhibits the results obtained by Guibourt in the analysis of various opiums. (*J. P. C.*, Jan., Feb. and March, 1862.)

Table showing percentage of morphine in varieties of opium (Guibourt).

Opium.		Soft.	Hard.	Dried.
Anatolia (Smyrna)	lowest	9.60	10.82	11.70
" "	highest	18.24	19.77	21.46

French	lowest		14.21	14.83
"	highest		21.10	22.88
"	mean		16.77	17.69

Adulterations.—The adulteration of opium has given rise to much complaint on the part of pharmacists, and various plans of customs legislation have been suggested by which it has been thought that these adulterations could be prevented. It is, however, obviously impossible to pronouncedly affect the action of the semi-barbarians who are engaged in the cultivation of opium, by any American legislation. Usually the substances which are used to adulterate the drug are inert, and therefore do no harm except by weakening its activity. The U. S. Custom House requires that opium, in order to enter the United States as opium, shall conform to the U. S. P. standard and contain not less than 9.5 per cent. of anhydrous morphine.

It is asserted by some French writers that extensive frauds are practised at Marseilles. The opium taken thither from the Levant is first softened, and then adulterated with various matters which are incorporated in its substance. To use a strong expression of Guibourt, they make the opium over again at Marseilles. According to A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum arabic, tragacanth, salep, aloes, even small stones and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. Tschirch (*A. J. P.*, 1898, 488) proposes the use of the Roentgen ray in detecting such adulterations.

Masson described a product which was sold under the name of "Smyrna" or "manipulated," and which consisted of a mixture of the natural juice with substances more or less inert. The samples varied very widely in composition, and in some cases were so altered that the active ingredients could not be readily dissolved. (*J. P. C.*, 1905, p. 529.) Stahl found in some samples of Turkish opium the possible admixture of fruit pulp or fruit extracts. (*Ph. Zentralh.*, xlix, p. 958.)

Landerer, of Athens, was informed by a person who had been engaged in the extraction of opium, that grapes, freed from their seeds and crushed, were almost universally mixed with the poppy juice, and that another adulteration consisted of the epidermis of the capsules and stem of the plant, pounded in a mortar with the white of an egg. (*A. J. P.*, xv, 238.) According to Wilkins, who witnessed the collection of opium, the inspissated juice of the grape, thickened with flour, is often used for the same purpose. (*P. J.*, xiv, 400.)

Opium is regarded as inferior when it has a blackish color, a weak or empyreumatic odor, a sweet or slightly nauseous and bitter taste, a soft, viscid, or greasy consistence, a dull fracture, or an irregular, heterogeneous texture, from the intermixture of foreign substances. It should not impart a deep-brown color to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

Properties.—Good opium has a strong, peculiar odor, and a bitter, somewhat acrid taste. It is officially described as "in more or less rounded, mostly somewhat flattened masses of variable size, but usually about 8 to 15 cm. in diameter; externally grayish-brown, covered with fragments of poppy leaves and at times with some fruits of a species of rumex adhering from the packing; more or less plastic when fresh, becoming hard and brittle on keeping; internally dark brown, interspersed with lighter areas, somewhat lustrous; odor characteristic, narcotic; taste bitter, characteristic. For a description of the powder, see *Opii Pulvis*." *U. S.*

"Usually in rounded, irregularly formed, or flattened masses, varying in weight, but commonly weighing from about 250 to 1000 grammes. When fresh, plastic, and internally somewhat moist, coarsely granular, or nearly smooth, and reddish or chestnut-brown; but becoming harder on keeping, and darkening to blackish-brown. Strong and characteristic odor; taste bitter." *Br.*

When long chewed it excites much irritation in the lips and tongue, and may even blister the mouths of those unaccustomed to its use. Its color is reddish-brown or deep fawn; its texture compact; its sp. gr. 1.336. When drawn over paper it usually leaves an interrupted trace of a light-brown color. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording, when pulverized, a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. On heating opium on a watch crystal and collecting the sublimate on a slide, Rosenthaler found the sublimate to give the characteristic red color reaction for narcotine. (*Ph. Zentralh.*, liv, p. 1250; *Apoth. Zeit.*, xxviii, p. 991.)

Opium yields its virtues to water, alcohol, and diluted acids, but not to ether, benzine and some of the other immiscible solvents. To all these menstrua it imparts a deep-brown color. Alcohol dissolves about four-fifths of it. Pelletier stated that the proportion taken up by water varies in the specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16.

Chemical Constituents.—Much attention has been devoted to the chemical constitution of opium. It was through the researches into the nature of this substance that chemists were led to the discovery of the alkaloids. To Sertürner, an apothecary at Eimbeck, in Germany, belongs the credit of having opened the important field of alkaloidal research. The development of the alkaloids in opium has been the object of the studies of A. Müller. (*Ph. Ztg.*, lix, p. 600.) He found the seeds to be alkaloid free, but that the sprouts, after two weeks, show the presence

of alkaloids. The alkaloidal content of the plant slowly increases until the flowers appear, when there is a sharp increase lasting until the floral leaves fall. After the ripening of the capsule, the alkaloidal nitrogen content of the entire plant was found to be 0.0094 per cent.; of the stem and leaves alone, 0.0085 per cent.; and of the capsule walls only 0.0168 per cent. The alkaloidal content was found to vary from day to day, being less on cloudy than on sunny days. His conclusions were that the alkaloids of the poppy plant are not excretion material intended to protect the plant from animal enemies, as has been suggested, but that they are present to afford a source of nitrogen for the synthesis of reserve protein. A comprehensive study of the market conditions of the more important opium alkaloids was contributed by L. E. Warren, *A. J. P.*, 1915, p. 439.

In the year 1803 Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year Seguin discovered another crystallizable body, which experience has proved to be the true narcotic principle of opium, but he did not fully investigate its nature, and no immediate practical advantage accrued from his excellent analysis. About the same time, Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained until 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance which, though discovered both by Seguin and himself, had been hitherto but vaguely known. To the alkaloid, in which he correctly conceived the narcotic powers of opium to reside, he gave the name of *morphium*, which has been since changed to *morphine*, in order to render it conformable with the titles of the other alkaloids. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne and called by him the *salt of opium* was a principle altogether distinct from morphine, though supposed to possess considerable influence over the system. In the belief in its narcotic powers, Robiquet denominated it *narcotine*, a title which it still retains. A number of other alkaloids have since been discovered in opium, although most of these are in very limited amount, and the existence of some is not quite definitely established. According to the views of its constitution at present accepted, it contains: (1) *Morphine*, $C_{17}H_{19}O_3N$; (2) *Codeine*, $C_{18}H_{21}O_3N$; (3) *Thebaine*, $C_{19}H_{21}O_3N$; (4) *Papaverine*, $C_{20}H_{21}O_4N$; (5) *Meconidine*, $C_{21}H_{23}O_4N$; (6) *Codamine*, $C_{20}H_{25}O_4N$; (7) *Laudanidine*, $C_{20}H_{25}O_4N$; (8) *Laudanine*, $C_{20}H_{25}O_4N$; (9) *Laudanosine*, $C_{21}H_{27}O_4N$; (10) *Lanthopine*, $C_{23}H_{25}O_4N$; (11) *Protopine*, $C_{20}H_{19}O_5N$; (12) *Cryptopine*, $C_{21}H_{23}O_5N$; (13) *Rhœadine*, $C_{21}H_{21}O_6N$; (14) *Narcotine*, $C_{22}H_{23}O_7N$; (15) *Oxynarcotine*, $C_{22}H_{23}O_8N$; (16) *Narceine*, $C_{23}H_{29}O_9N$; (17) *Pseudomorphine*, $C_{34}H_{36}O_6N_2$; (18) *Gnoscopine*, $C_{22}H_{23}O_7N$; (19) *Xanthaline*, $C_{37}H_{36}O_9N_2$; (20) *Tritopine*, $C_{42}H_{54}O_7N_2$; (21) *Hydrocotarnine*, $C_{12}H_{15}O_3N$. In addition to the above list, *Deuteropine*, *Opianine*, *Papaverosine*, and *Porphyroxine* are possible alkaloids that have been announced, but not sufficiently established as yet. Still others, like *Apomorphine* (see p. 157), can be produced from those existing in the opium. At least two acids occur in opium combined with these bases —*meconic acid*, $C_7H_4O_7$, and *lactic acid*, $C_3H_6O_3$. This latter, supposed by T. and H. Smith to be a peculiar variety of lactic acid, and named by them *thebolactic acid*, was ascertained by Stenhouse to be the ordinary variety. Sulphuric acid is found in the ash along with the bases calcium, magnesium, and potassium. Opium also contains mucilage, pectic matter, and a glucose sugar. The wax gathered from the refuse of opium yielded Hesse cerotyl palmitate and cerotate. Three neutral pirinciples have, moreover, been extracted from opium—*meconin* (*opianyl*), $C_{10}H_{10}O_4$, *meconoisin*, $C_8H_{10}O_2$, and *opionin*, which, according to Hesse, is contained in small quantities in Smyrna opium. The first of these forms prisms which fuse under water at 77° C. (170.6° F.), or *per se* at 110° C. (230° F.), and boil at 155° C. (311° F.); the second melts at 88° C. (190.4° F.), and the third at 227° C. (440.6° F.). None of these neutral principles contain nitrogen. All the organic bases of opium polarize to the left. (Bouchardat and Boudet, *J. P. C.*, 3e sér., xxiii, 294.)

Of the principles above mentioned, *morphine* is by far the most important. It is generally admitted to exist in opium united with meconic acid in the state of meconate, and to a certain extent also as a sulphate, although A. R. L. Dohme (*A. J. P.*, 1891, p. 168) believes that the results of a dialysis of opium show that the morphine is combined with sulphuric acid alone. Smith, of Edinburgh, obtained from 100 parts of fine opium, 10 parts of morphine, 6 of narcotine, 0.15 of thebaine, 1 of papaverine, 0.3 of codeine, 0.02 of narceine, 0.01 of meconin, 4 of meconic acid, and 1.25 of theobolactic acid. (*P. J.*, Oct., 1865, p. 183.)

Codamine.—*Codamina*, $C_{20}H_{25}O_4N$, is isomeric with laudanine, but is readily distinguished from it by the effect of ferric chloride and nitric acid, both of which color it deep green. According to Allen, codamine also gives a dark green coloration with sulphuric acid and, in the presence of a minute quantity of ferric chloride, a greenish-blue. It is in anhydrous crystals. It can be purified by taking advantage of the feeble solubility of its iodide. Hav-

ing decomposed this salt by ammonia, dissolve the precipitate in ether, wash the ethereal solution with solution of sodium bicarbonate, then filter through animal charcoal. By evaporation the liquid deposits the alkaloid in beautiful colorless crystals. Codamine crystallizes also from petroleum benzin; but thus obtained it melts at 126° C. (258.8° F.), while that procured through ether melts at about 120° C. (248° F.). The acid iodide, tartrate, and oxalate are crystallizable.

CODEINE.—*Codeina,* $C_{18}H_{21}O_3N$ (or $C_{17}H_{17}NO(OH).OCH_3$), was discovered in 1832 by Robiquet in morphine hydrochloride prepared according to the process of Gregory, and was prepared synthetically by Grimaux by the action of methyl iodide and sodium hydroxide upon morphine, thus proving its chemical character as a morphine methyl-ether (Allen). It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochloride. (See *Morphina.*) When the solution of the mixed morphine and codeine hydrochlorides is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them, and yields the codeine in colorless crystals by spontaneous evaporation. This alkaloid and its phosphate and sulphate are now official. (See *Codeina.*) For a paper on the determination of codeine in opium, by Chas. E. Caspari, see *Proc. A. Ph. A.,* 1904, 386. Dobbie and Lauder (*J. Chem. S.,* 1911, xcix), describe a new alkaloid, *neopine,* which they believe to be a *hydroxycodeine.*

CRYPTOPINE. *Cryptopina,* $C_{21}H_{23}NO_5$.—This alkaloid was discovered by T. and H. Smith, of Edinburgh. (*P. J.,* 1867, p. 595.) They obtained it from the weak alcoholic washings of crude morphine after precipitation, by precipitating with milk of lime, and separating from the thebaine by fractional crystallization. (For details of their method, see *U. S. D.,* 19th ed., p. 895.) To obtain the pure alkaloid, it is precipitated from solution of the hydrochloride by ammonia, washed, dried, and finally washed with ether or alcohol, which readily dissolves thebaine, but has little effect on cryptopine. It may be obtained in a crystallized state by boiling it with a large quantity of alcohol, which, on cooling, will slowly deposit the alkaloid in crystals. The quantity in opium is extremely small.

Cryptopine is without color or odor, and its salts, though at first bitter to the taste, afterward cause a sense of coolness in the mouth, like that produced by peppermint. It melts at 217° C. (422.6° F.), and, on cooling, crystallizes in radiated forms at 171° C. (339.8° F.), and, heated to redness, is decomposed, blackening and giving forth aqueous vapors, but without properly subliming. It is insoluble in water and in ether, very sparingly soluble in alcohol, requiring 1265 parts of that liquid when cold to dissolve it. Chloroform dissolves it almost as freely as narcotine. Oil of turpentine and benzene do not appear to dissolve it. It has very strong alkaline powers, and forms crystallizable salts with the acids, which are distinguishable from all the other salts of the opium alkaloids by a strong tendency to gelatinize. If the hydrochloride is dissolved in about 30 parts of hot water, and set aside, instead of crystallizing, it forms a jelly closely resembling that of pure gelatin. From all the constituents of opium, except the alkaloids, morphine, codeine, and thebaine, it is distinguished by its strong alkaline properties. From morphine it is distinguished by its very sparing solubility in alcohol, and from codeine and thebaine by its total insolubility in ether. It differs also in the effect of strong sulphuric acid, which produces a blue color with the minutest quantity of cryptopine, a blood red with thebaine, and none with morphine or codeine.

DEUTEROPINE, $C_{20}H_{21}O_3N$, according to Allen, is an alleged homologue of protopine and cryptopine. It requires further examination.

GNOSCOPINE, $C_{22}H_{23}O_7N$, was found by T. and H. Smith in 1878. They first gave to it the formula $C_{34}H_{36}O_{11}N_2$, but in a later communication (*P. J.,* 1893, 1794) gave it the simpler formula which makes it an isomer of narcotine. It is crystallizable, melts at 233° C. (451.4° F.), with partial decomposition, is soluble in chloroform and carbon disulphide, slightly so in benzene, not in ether. The salts have an acid reaction.

HYDROCOTARNINE.—*Hydrocotarnina,* $C_{12}H_{15}O_3N$, is obtained from the mother waters of thebaine, after the removal of cryptopine and protopine with warm petroleum benzin, by precipitation with ammonia; laudanosine, which is also precipitated, is removed by treatment of the benzin solution with sodium bicarbonate. The hydrocotarnine is retained in solution by the benzin, from which the laudanosine has been deposited on cooling. Hydrochloric acid gas being made to pass through this solution, hydrocotarnine hydrochloride crystallizes out. This alkaloid, as the name indicates, can be formed from cotarnine, by the action of zinc and hydrochloric acid. It also seems to result from the decomposition of narcotine. (See *Narcotine.*) If the latter be made to boil some time with baryta water, a portion of it will be decomposed, giving rise to a crystallizable substance soluble in ether, which appears to be identical with hydrocotarnine. This alkaloid is very soluble in alcohol, acetone, chloroform, benzin, and ether. It melts at 50° C. (122° F.), and loses at 57° C. (134.6° F.) the half molecule of water with which it crystallizes. Sulphuric acid dissolves it, coloring it yellow in the cold, and crimson red if heated. Nitric acid colors it yellow; ferric chloride does not affect its color. It has been physiologically studied by

Stockman and Dott (*B. M. J.*, Jan., 1891), who find that it produces in the lower animals symptoms similar to those caused by narcotine.

LANTHOPINE.—*Lanthopina,* $C_{23}H_{25}O_4N$, differs from pseudomorphine in not becoming blue with ferric chloride, and in giving, when entirely pure, with sulphuric and nitric acids, colorless solutions. It forms colorless microscopic prisms, which fuse at about 200° C. (392° F.). Its acid oxalate and tartrate are crystallizable. The alkaloid is crystallizable, does not have an alkaline reaction, is sparingly soluble in hot or cold alcohol, ether, or benzene, but readily soluble in chloroform. (See *U. S. Dispensatory,* 19th ed., p. 896.) According to Allen, it is obtained from the mother liquor, left from the preparation of morphine by the Robertson-Gregory process. It is a weak base, and is colored orange-red by nitric acid, and pale violet by sulphuric acid, the latter color changing to a dark brown on heating.

LAUDANIDINE, $C_{20}H_{25}O_4N$, was discovered by Hesse in 1894. It closely resembles laudanine.

LAUDANINE.—*Laudanina,* $C_{20}H_{25}O_4N$, as first prepared, is mixed with cryptopine, from which it is separated by dissolving it in acetic acid, and adding a slight excess of diluted solution of sodium hydroxide, by which the cryptopine is entirely precipitated. The liquid being filtered, and treated with ammonium chloride, lets fall the laudanine, which soon assumes the crystalline form. The acetate, with the addition of potassium iodide, gives rise to laudanine hydriodide, from which ammonia separates the base perfectly pure. It crystallizes from its solution in boiling alcohol in transparent granules or hexagonal prisms melting at 166° C. (330.8° F.). It is lævorotatory, tasteless, and poisonous, the hydrochloride resembling strychnine in its effects. It is dissolved at 18° C. (64.4° F.) by 647 parts of ether. Sulphuric acid gives with it characteristic reactions. When pure, at common temperatures it assumes a pale rose color, and at 150° C. (302° F.) a reddish-violet. When ferric oxide is added, it exhibits the same changes, but with much greater intensity. Laudanine is an energetic base, and with potassium hydroxide forms a crystallizable compound. Its salts, except the neutral sulphate, oxalate, and tartrate, are crystallizable.

LAUDANOSINE.—*Laudanosina,* $C_{21}H_{27}O_4N$, exists in the mother waters of thebaine, with cryptopine and protopine. The thebaine having been precipitated by tartaric acid, the mother water is neutralized by ammonia, and sodium bicarbonate is added. After eight days' rest, a blackish mass separates. The limpid liquid with an excess of ammonia yields a copious precipitate, which, agitated with heated petroleum benzin, gives to that liquid a mixture of several alkaloids. The benzin solution upon cooling to 40° C. (104° F.), deposits the cryptopine and protopine. On agitation anew with heated sodium bicarbonate and subsequent complete refrigeration, the laudanosine crystallizes. It is entirely purified by ether, which dissolves it abundantly, and its hydriodide is but slightly soluble in water. It is itself insoluble in water and the alkalies, but it is soluble in alcohol, acetone, and chloroform. It melts at 89° C. (192.2° F.), and is decomposed at 110° C. (230° F.). Ferric chloride does not color it. Sulphuric acid gives it a rose color in the cold, and violet when heated. Nitric acid transforms it into a nitro-base. The crystals are anhydrous. It forms crystallizable salts, which are soluble and bitter.

MECONIDINE, $C_{21}H_{23}O_4N$, was discovered by Hesse in 1870. It is brownish-yellow, amorphous, alkaline, melts at 58° C. (136.4° F.), and is not stable, the salts also being easily altered. It is easily soluble in alcohol, ether, benzene, chloroform, and acetone. It is dissolved by sulphuric acid with an olive-green color, and by nitric acid with an orange-red.

MORPHINE, $C_{17}H_{19}O_3N + H_2O$, and its preparations are treated under another head. (See *Morphina.*)

NARCEINE, *Narceina,* $C_{23}H_{29}O_9N$, discovered by Pelletier in 1832, is in white, silky crystals, inodorous, of bitter taste, the fusing point of which was given at 145.2° C. (293.3° F.) according to Hesse, and as 92° C. (197.6° F.) according to Pelletier. E. Merck has shown, however (*Chem. Ztg.,* 1889, p. 525), that the ordinary commercial alkaloid of English manufacture melts between 150° and 160° C. (302°–320° F.) and the pure base at 170° to 171° C. (338°–339.8° F.). Out of water at 60° C. (140° F.) it crystallizes with 2 molecules of water, which it loses at 100° C. (212° F.) and at 140° C. (284° F.) another molecule of water escapes, leaving in the fused residue a mixture of bases. Soluble in 375 parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It forms a bluish compound with iodine, the color of which is destroyed by heat and the alkalies. Besides, according to Stein, the blue color is not produced when there is too much of the iodine present, which then causes a brown color with narceine, the blue color appearing under such circumstances, only when the excess of iodine is saturated by ammonia. (*J. P. C.,* Jan. 1872, p. 59.) It is rendered blue by the action of mineral acids so far diluted as not to decompose it, but it does not, like morphine, become blue by the action of ferric salts, nor red by that of nitric acid. According to P. C. Plugge, if a trace of narceine be covered in a porcelain dish with *diluted* sulphuric acid, no change will be observable; but if the dish be heated on the water bath, a blue color will be developed as soon as the acid has become sufficiently concentrated; this by prolonged heating will pass to cherry-red. If to this red liquid, after cooling, a trace of nitric acid or potassium nitrite be added, blue-violet streaks will be produced. (*A. Pharm.,* 1887, p. 425.) It is dissolved by the acids, but was thought not to neutralize them, and, though at first considered alkaline by

Pelletier, was afterwards ranked with indifferent bodies. At present, however, its alkaloidal character is admitted; it unites with sulphuric acid to form a crystallizable sulphate. (*J. P. C.*, April, 1864, p. 367.) Dragendorff announced that solution of narceine gives a crystalline precipitate with the double zinc and potassium iodide. This reaction may be employed with iodine as a test of narceine. If a solution of this salt, with a little iodized water, be added to solutions of narceine, and the mixture then agitated with ether to remove the iodine in excess, a solution containing a very small quantity of narceine will distinctly assume a blue color. The other alkaloids of opium are destitute of this property. (*J. P. C.*, April, 1870, p. 346.) Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphine by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta water, separated the excess of baryta by ammonium carbonate, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, on cooling, deposited crystals of narceine, which were easily purified by repeated solution and crystallization. Meconin, which often crystallizes with it, may be separated by the agency of ether. The discordancy of the statements of physiologists and clinicians concerning the action of narceine can only be explained by the presence of impurities in the specimens used. The pure alkaloid would seem to be very feeble in its influence, Mitchell having taken five grains without any other effect than causing some headache. The narceine of commerce has been used in doses of one-third to three-fourths of a grain (0.021–0.048 Gm.) as a mild narcotic, probably acting through contaminating morphine.

NARCOTINE. *Narcotina*, $C_{22}H_{23}O_7N$.—It exists in opium, chiefly, at least, in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous, and crystallizes in silky flexible needles, usually larger than the crystals of morphine, fusible at 176° C. (349° F.), and decomposes at higher temperature with evolution of ammonia. Heated to 220° C. (428° F.), the residue which remains is *hemipinic acid*, $C_{10}H_{10}O_6$, insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol, which deposits it upon cooling, and very soluble in ether. The fixed and volatile oils, and the diluted acids, also dissolve it; and it has been found to be soluble in the volatile oil of turpentine, which, aided by heat, will extract it from opium, and yield it in crystals by evaporation. (*J. P. C.*, 4e sér., ii, 156.) As it exerts no alkaline reaction upon vegetable colors, and does not prevent the acids from reddening litmus paper, there would appear to be some reason for denying it the rank of an alkaloid. But it unites with some of the acids, forming definite compounds, which may be procured in a separate state; and Robiquet obtained narcotine sulphate and hydrochloride well crystallized. (*J. P. C.*, xvii, 639, and xix, 59.) Hence it is now generally considered as a weak base, and perhaps this view of it is the most convenient. It must be admitted, however, to have a very feeble neutralizing power. With acetic acid it does not appear to form a permanent combination, for, though dissolved by cold acetic acid, it is separated by heating the solution. It is decomposed by long boiling, or by heating with nitric acid, into *cotarnine*, $C_{12}H_{13}O_3N$ (see p. 384) and *meconin*, $C_{10}H_{10}O_4$, and by heating with water to 100° C. (212° F.) in sealed tubes, into *hydrocotarnine*, $C_{12}H_{15}NO_3$, and *opianic acid*, $C_{10}H_{10}O_5$, while, on the other hand, the action of nascent hydrogen (from zinc and hydrochloric acid) converts it into *hydrocotarnine* and *meconin*, and that of oxidizing agents into *cotarnine* and *opianic acid*. It may be distinguished from morphine by its insipidity, by its solubility in ether and insolubility in alkaline solutions, by not affecting vegetable colors, by assuming a yellowish instead of a blood-red color under the action of strong nitric acid, by not decomposing iodic acid, and by not producing a blue color with ferric salts. It is, however, reddened by a mixture of nitric and sulphuric acids. Hence, if to a mixture of it with strong sulphuric acid a small piece of potassium nitrate is added, a deep blood-red color is produced; while morphine, under the same circumstances, yields a brownish or olive green color. It gives a greasy stain to paper when heated upon it over a candle. Distilled with potassium hydroxide, or simply by heating to 250° C. (482° F.), it yields *trimethylamine*, $N(CH_3)_3$. Heated with strong hydrochloric acid, it loses two groups, CH_2, and with concentrated hydriodic acid a third, CH_2, so that the existence of three methyl groups (CH_3) in narcotine have been established. Water extracts narcotine partially from opium, in consequence of the acid which the latter contains, either free or combined with the narcotine. It is usually obtained mixed with morphine in the processes for procuring that principle, and may be separated by the action of ether, which dissolves it without affecting the morphine, and yields it upon evaporation. It may also be obtained by digesting opium in ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotine. It is said that the same result may be obtained by using the oil of turpentine as the menstruum, first heating it with opium, and then evaporating the solution. Another mode of procuring it is to treat opium, exhausted by previous maceration in water, with diluted acetic acid, filter the solu-

tion, precipitate by an alkali, wash the precipitate with water, and purify it by solution in boiling alcohol, from which it crystallizes as the liquid cools. Should it still be impure, the solution in alcohol and crystallization may be repeated. The proportion of narcotine in opium varies extremely in the different varieties, and in different specimens of the same variety. Thus, in Smyrna opium it has been found by different observers, in quantities varying from 1.30 to nearly 11 per cent. Though narcotine itself is tasteless, its salts are very bitter, even more so than those of morphine. (Berzelius.) Their solution reddens litmus, and yields precipitates with the alkalies and infusion of galls. For physiological study of the methylamide derivatives of narcotine (*narcotine methylamide*), see *V. A. P. A.*, 142, 1895.

ANARCOTINE has been described as an alkaloid especially abundant in the India opium. According to Wm. Roberts (*B. M. J.*, 1895, ii), while Smyrna opium containing 8 per cent. of morphine has in it 2 per cent. of anarcotine, Bengal opium contains 4 per cent. of morphine with 6 per cent. of anarcotine. Anarcotine appears, however, to be simply pure narcotine. (*Merck's Jahresber.*, 1896, 101.) It is said to be nearly destitute of active physiological properties. In the experiments of Surveyor (*B. M. J.*, 1896), one drachm of it given subcutaneously to an anesthetized dog produced no sensible effect. The continuous use of it in large doses seemed, however, to affect the nutrition of the dog. It was at one time largely used in India as an antiperiodic on account of its being cheaper than quinine, but has fallen into desuetude because of the present low price of the cinchona alkaloids.

It has been asserted that narcotine is identical with *aconella*, an alkaloid said to have been extracted by the Messrs. Smith, of Edinburgh, from aconite, but Groves failed to find aconella. (See page 79, *U. S. D.*, 14th edition.) Many years ago O'Shaughnessy, of Calcutta, recommended narcotine as an antiperiodic, in doses of three grains (0.2 Gm.) three times a day, but it has failed to acquire reputation. See an elaborate paper on the pharmacology of narcotine by A. C. Crawford and A. R. L. Dohme, *Proc. A. Ph. A.*, 1902, 472.

OPIANINE, which has been claimed to have the formula $C_{21}H_{21}O_7N$, is now supposed to be impure narcotine.

OXYNARCOTINE. *Oxynarcotina*, $C_{22}H_{23}O_8N$.—This alkaloid accompanies narceine, from which it can be separated by treating the mixture with dilute sulphuric acid. On neutralizing the solution with the theoretical amount of sodium hydroxide and heating to boiling, a part dissolves. The undissolved residue is the oxynarcotine. It can also be obtained from the mother liquors of narcotine. According to Beckett and Wright, it crystallizes out of alcohol in very fine needles, which are difficultly soluble in boiling water and boiling alcohol, insoluble in other neutral solvents. Heated to 140° or 150° C. (284° or 302° F.) it is carbonized. It is oxidized by ferric chloride to *hemipinic acid* and *cotarnine*. It is a monacid base, and forms crystallizable salts.

PAPAVERINE. *Papaverina*, $C_{20}H_{21}O_4N$.—The discovery of this alkaloid was announced by G. Merck. It is crystallizable in needles, fusing at 147° C. (296.6° F.), insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids boiling hot, and deposited by them on cooling. With acids it forms salts, most of which are very sparingly dissolved by water. The hydrochloride crystallizes with extraordinary facility. The alkaloid is readily dissolved by moderately concentrated hydrochloric acid, from which, on the addition of more acid, the hydrochloride separates, assuming the form of an oily layer at the bottom of the vessel, which is readily converted on standing into a mass of acicular crystals. These crystals are very sparingly soluble in cold water. The hydrochloride yields with platinic chloride a yellow precipitate which is insoluble in boiling water or alcohol. By the action of hydrochloric acid at 130° C. (266° F.), however, it is decomposed into methyl chloride and homopyrocatechol. By the action of concentrated nitric acid there is formed, on heating, the nitrate of nitropapaverine, $C_{20}H_{20}(NO)_2O_4.NHNO_3$, which separates in crystals. The nitro-base can be separated in clear yellow flocks by the addition of ammonia. By the action of tin and hydrochloric acid there is formed a tetrahydropapaverine, $C_{20}H_{25}O_4N$. Cold concentrated sulphuric acid does not color it, but on warming a violet color is obtained; an impure papaverine is colored violet, however, with sulphuric acid even in the cold. Papaverine is prepared by precipitating the aqueous infusion of opium with soda, exhausting the precipitate with alcohol, evaporating the tincture to dryness, treating the residue with a dilute acid, filtering, precipitating by ammonia, dissolving the precipitate in hydrochloric acid, mixing sodium acetate with the solution, and treating the resulting precipitate with boiling ether. The ethereal solution deposits the papaverine on cooling. Leubuscher (*D. M. W.*, 1892) asserts that it acts as a sedative to intestinal peristalsis without producing other effects, and is valuable in the *diarrhea* of children.

Dose, for a two-year-old child, two-fifths of a grain (0.024 Gm.), repeated three or four times a day.

PORPHYROXINE, according to K. L. Dey (*P. J.* [3], xii, p. 397), is a definite basic substance, always present in Indian opium, but absent from Turkey or Smyrna opium.

PROTOPINE.—*Protopina*, $C_{20}H_{19}O_5N$, is an alkaloid which Hesse separated from cryptopine. Both are precipitated as insoluble hydrochlorides by hydrochloric acid in excess; but if the precipitate be dissolved by an excess of oxalic acid, the acid cryptopine oxalate will crystallize, and protopine remain in the mother waters. The liquid is separated, precipitated

by ammonia, and agitated with ether, and the ethereal solution is taken up by hydrochloric acid. Protopine hydrochloride being dense and granular, while cryptopine hydrochloride is very light, the two are separated by levigation —eighty grammes of crude cryptopine furnishing one and a half of protopine. Separated from the hydrochloride by ammonia, protopine constitutes a crystalline powder, insoluble in water, soluble in alcohol and in hot petroleum benzin and acetone, more soluble in chloroform, insoluble in the alkalies generally, but slightly soluble in ammonia. It melts at 202° C. (395.6° F.), undergoing decomposition, and is in anhydrous crystals. Ferric chloride does not color it; nitric acid colors it yellow; sulphuric acid dissolves it, coloring it first yellow, then red, and lastly violet. The alcoholic solution has an alkaline reaction. The salts are neutral and crystallizable.

E. Schmidt (*A. Pharm.*, 231 (1893), 136) states that protopine is identical with *maclayine*, an alkaloid, which has been found by Eykman in *Maclaya cordata*, and that it is also found in *Sanguinaria canadensis*, *Stylophorum diphyllum*, *Eschscholtzia californica*, and other plants.

PSEUDOMORPHINE.—*Pseudomorphina*, $C_{34}H_{36}O_6N_2$, was discovered by Pelletier in 1835, and is said by Hesse to be identical with Polstorff's *oxydimorphine;* but, as it exists in small quantities, and was thought to be only an occasional ingredient in opium, little attention has been paid to it. An interesting fact, however, in relation to it, and one of some toxicological importance, is that it possesses two properties considered characteristic of morphine, those, namely, of being reddened by nitric acid and of striking a blue color with ferric salts, and yet it is without any poisonous influence upon the animal economy. (*J. P. C.*, xxi, 575.) Hesse has investigated the subject, with the following results. He found that it accompanies morphine procured by Gregory's method, and may be separated from that alkaloid by adding ammonia in excess to an alcoholic solution containing both. The morphine is precipitated, and pseudomorphine, remaining in solution, may be obtained by evaporating the mother liquid. It is probably produced from morphine by the following reaction:

$$2C_{17}H_{19}O_3N - H_2 = C_{34}H_{36}O_6N_2.$$

It is tasteless, insoluble in water, alcohol, ether, chloroform, and diluted sulphuric acid, but easily soluble in solution of potassium and sodium hydroxide, and lime, and in alcoholic solution of ammonia, though sparingly in an aqueous solution of ammonia. It does not neutralize hydrochloric acid, dissolves in concentrated sulphuric acid with the production of an olive-green color, in concentrated nitric acid with an intense orange-red, and in solution of ferric chloride with a blue color. At 120° C. (248° F.) it loses two molecules of water of crystallization, and at higher temperatures is decomposed without melting. It forms sparingly soluble salts with sulphuric, nitric, oxalic, and tartaric acids, and a crystalline deposit, very slightly soluble in hydrochloric acid, with solution of corrosive sublimate. (*Chem. News*, 1867, p. 188.) Hesse is of the opinion that pseudomorphine is identical with the oxymorphine prepared by the action of oxidizing agents upon morphine by Schutzenberger.

RHŒADINE, $C_{21}H_{21}O_6N$, discovered by Hesse in 1865, is crystallizable, but not distinctly alkaline. It fuses at 232° C. (449.6° F.), and can be sublimed at higher temperatures. It is nearly insoluble in ether, alcohol, benzene, chloroform, water, and ammonia. Its solutions in dilute acids acquire an intense purple color on addition of strong hydrochloric or sulphuric acid, due to the formation of a coloring matter. This is destroyed by alkalies and restored by acids, and is so intense that 1 part of rhœadine will color 10,000 parts of water purple-red, 200,000 deep rose-red, and 800,000 distinctly red, although only a portion of the base is converted into coloring matter. The solution then filtered through bone-black shows the presence of a base, *rhœagenine*, isomeric with rhœadine, but fusing at 223° C. (433.4° F.), and forming a different series of salts. This alkaloid occurs also in *Papaver Rhœas*.

THEBAINE (*Paramorphina*).—*Paramorphine*, $C_{19}H_{21}O_3N$ (or $C_{17}H_{15}ON(OCH_3)_2$), was discovered by Pelletier in the precipitate thrown down from an infusion of opium treated with milk of lime. The precipitate being washed with water until the liquid came away colorless, and then treated with alcohol, instead of affording morphine to this solvent, as was anticipated, yielded a new alkaloid, which was obtained separate by evaporating the alcohol, acting on the residue with ether, allowing the ethereal solution to evaporate spontaneously, and then purifying the resulting crystalline mass by dissolving it in an acid, precipitating by ammonia, and recrystallizing by means of alcohol or ether. Pelletier named it paramorphine, from its close analogy in composition with morphine, from which, however, it is quite distinct in properties. The name of *thebaine* was proposed for it by Couërbe, who was disposed to give the credit of its discovery to Thiboumery, the director of Pelletier's laboratory. It is white, crystallizable, and of an acrid and styptic rather than bitter taste, fusing at 193.4° C. (380° F.), and, according to Hesse, confirmed by D. B. Dott, is not sublimable. Other observers state that it sublimes at 135° C. (275° F.) without fusing, and is deposited in minute crystals resembling caffeine. It is scarcely soluble in water, very soluble in alcohol and ether when cold, and still more so when heated, and capable of combining with the acids, with which it forms salts not crystallizable from their aqueous solution. Alkalies precipitate it from its acid solutions, and unless in very concentrated solution, do not dissolve it when added in excess. It is not like morphine, reddened

by nitric acid, nor does it become blue with solutions of ferric salts. From codeine it differs in never being in large crystals, in not forming crystallizable salts, in being always precipitated from its acid solutions by ammonia, and in not melting in oily drops. From narcotine, which it most resembles, it may be distinguished by its shorter crystals, which lack the pearly appearance of those of narcotine, by its different taste, by its much greater solubility in cold alcohol, of which 10 parts will dissolve 1 of this principle, while narcotine requires 100 parts, and by the action of nitric acid, which converts it into a resin-like matter before dissolving it, while the same acid instantly dissolves narcotine. Diluted sulphuric or hydrochloric acid in excess changes thebaine, according to Hesse, into two isomeric bases, *thebenine* and *thebaicine*. When heated to 90° C. (194° F.) under pressure with fuming hydrochloric acid, thebaine yields a base having the probable formula $C_{17}H_{15}NO(OH)_2$, and called by its discoverer, W. C. Howard (*Ber. d. Chem. Ges.*, xvii, 527, xix, 1596), *morphothebaine*, to indicate its origin and relation to morphine.

Thebaine salicylate is practically insoluble in water; hence in the assay of opium the German Pharmacopœia directs the addition of sodium salicylate to the aqueous solution, thus removing the thebaine before precipitating the morphine.

Tritopine, $C_{42}H_{54}O_7N_2$, was discovered in 1890 by Klauder. (*A. Pharm.*, 228, p. 419.) It resembles morphine and laudanine in being soluble in sodium hydroxide solution, but is precipitated in the form of an oil by a large excess of the reagent. Tritopine crystallizes in characteristic, anhydrous, transparent, needle-like plates, melting at 182° C. (359.6° F.), easily soluble in chloroform, but only slightly so in ether. With sulphuric acid it behaves like laudanine. It appears to be a divalent base.

Xanthaline, $C_{37}H_{38}O_9N_2$, is a base obtained by T. and H. Smith (*P. J.*, 1893, 772) from the acid mother liquors resulting from the crystallization of morphine or codeine hydrochloride, and purification of the product.

Meconic Acid, $C_7H_4O_7 + 3H_2O$, is in white crystalline scales, of a sour taste followed by bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are that it produces a blood-red color with ferric salts, which is not destroyed by mercuric chloride as is the similar reaction produced by sulphocyanates, a green precipitate with a weak solution of ammoniated copper sulphate, and white precipitates, soluble in nitric acid, with lead acetate, silver nitrate, and barium chloride. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of calcium chloride. Calcium meconate and sulphate are precipitated. The precipitate, having been washed with hot water and with alcohol, is treated with diluted hydrochloric acid at 82.2° C. (180° F.). The calcium meconate is taken up, and, upon the cooling of the liquid, calcium bimeconate is deposited. This is dissolved in warm concentrated hydrochloric acid, which deposits pure meconic acid when it cools. It may be freed from coloring matter by neutralizing it with potassium hydroxide, decomposing the meconate thus obtained by hydrochloric acid, and again crystallizing. When heated, it loses first its water of crystallization, and then at 120° C. (248° F.) a molecule of CO_2, and yields *comenic acid*, $C_6H_4O_5$; this at 260° C. (500° F.) or over, loses another molecule of CO_2, and yields *pyromeconic acid*, $C_5H_4O_2$. By the action of nascent hydrogen (from sodium amalgam) it yields *hydromeconic acid*, $C_7H_{10}O_7$. Meconic acid has little or no action on the system, and is not used separately in medicine; but its natural relation to morphine requires that it should be understood. The three related compounds, meconic acid, comenic acid, and pyrocomenic acid, are now considered to be derivatives of the fundamental compound *pyrone*, $CO<\begin{matrix}CH=CH\\CH=CH\end{matrix}>O$. Thus, from pyrone, $C_5H_4O_2$, are obtained *oxypyrone* (pyromeconic acid), $C_5H_3O_2(OH)$, and *oxypyrone-carboxylic* (comenic) *acid*, $C_5H_2O_2(OH)COOH$, and *oxypyrone dicarboxylic* (meconic) *acid*, $C_5HO_2(OH)(COOH)_2$. Pyrone itself is formed when comenic and chelidonic acids are heated to 250° C. (482° F.). Most of the pyrone derivatives are converted by the action of ammonia into pyridone and pyridine compounds.

Meconic acid was formerly recognized by the British Pharmacopœia, but was dropped at the 1898 revision. It appears to be nearly free from active physiological properties. Sertürner took 4.5 grains of sodium meconate, and Grape and Loewer 12 grains of the pure acid, without the production of any symptoms, while, according to Mulder, Pereira, Lange, and others, 20 grains of the acid cause no sensible effect in the dog.

Meconin, $C_{10}H_{10}O_4$, a neutral principle before referred to, the existence of which was announced in 1832, by Couërbe, is identical with a substance discovered several years previously by Dublanc, Jr., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in alcohol, chloroform, and the essential oils, but only sparingly in ether; fusible under water at 77° C. (170.6° F.), *per se* at 110° C. (230° F.), sublimable on careful heating, and possessed of a degree of acrimony which favors the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the pre-

cipitate with water until the latter nearly ceases to acquire color, mixing the aqueous fluids, evaporating them to the consistence of molasses, setting them aside for two or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquid, while hot, and subjecting the crystals formed upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation. It may be produced from narcotine by oxidation with nitric acid.

MECONOISIN, $C_8H_{10}O_2$.—This principle was discovered by T. and H. Smith, in 1878, who obtained it from the oil-like liquid containing meconin, which, upon being left to itself for some days, sets into a mass of crystals. These crystals, upon being drained and cautiously washed with cold weak spirit, are to be boiled in a large quantity of water. The filtered liquid gives a crystallization of meconin, and the mother liquor, when concentrated, and upon being set aside for a time, yields beautiful leaf-like crystalline masses of meconoisin, fusing at 88° C. (190.4° F.). This principle is neutral, and it may be distinguished from meconin by the following test of T. and H. Smith. "When heated with slightly diluted sulphuric acid, and when the evaporation has reached a certain point, meconin produces a beautiful green color. With meconoisin, under the same circumstances, the coloration is deep red, becoming purple." This substance has been found by Stockman and Dott (*B. M. J.*, Jan., 1891) to be a tetanizant.

OPIONIN, as before stated, was found by Hesse in small quantities in Smyrna opium. It forms white needles, which melt at 227° C. (440.6° F.). These are insoluble in water, but dissolve in alkalies, alcohol, and ether.

LACTIC ACID, which was discovered by T. and H. Smith, of Edinburgh, and at first named by them thebolactic acid under the supposition that it differed from ordinary lactic acid, appears to be a constant ingredient in opium. These chemists were led to search for it by the consideration that the quantity of meconic acid present is insufficient to saturate the whole of the morphine and other bases, which must, therefore, be neutralized by some other acid. They obtained it from the impure mother liquid of morphine, after all the alkaloids had been thrown down by the addition of an alkali, by concentrating the liquors to a thick consistence, adding alcohol largely, filtering, precipitating any basic matter by sulphuric acid, filtering again, carefully neutralizing by milk of lime, distilling to recover the alcohol, and finally evaporating the residuary contents of the still to a syrupy consistence. After standing for about a week, the syrupy liquid will be seen to have set into a crystalline mass of calcium thebolactate. This, being purified by repeated solution and crystallization, and by animal charcoal, is decomposed by adding the equivalent quantity of sulphuric acid, and separating the liberated thebolactic acid by means of alcohol. Stenhouse showed that the new acid had the composition of lactic acid and was identical with the common variety, and his results were confirmed by J. Y. Buchanan. (*Ber. d. Chem. Ges.*, 1870, p. 182.) The ready crystallization of its salts with lime is a characteristic property.

Morphiometric Assays of Opium.—The proportion of morphine which any particular specimen of opium will furnish may be considered the best test of its value, except that of actual trial upon the system. The U. S. Pharmacopœia directs that opium, in its normal, moist condition should contain not less than 9.5 per cent. of anhydrous morphine, and powdered or granulated opium, dried at a heat not exceeding 85° C. (185° F.), should contain not less than 10 nor more than 10.5 per cent. of anhydrous morphine when assayed by the official process, which is as follows:

Assay of Opium. U. S. P. IX.—"Introduce 8 Gm. of Opium, which if fresh should be in very small pieces, and if dry in fine powder, into an Erlenmeyer flask having a capacity of about 250 mils, add 80 mils of distilled water, stopper the flask, and agitate it every ten minutes (or continuously in a mechanical shaker) during three hours. Then pour the contents as evenly as possible upon a wetted filter having a diameter of not over 12 cm., and, when the liquid has drained off, wash the residue with distilled water, carefully dropped upon the edges of the filter and its contents, until 120 mils of filtrate have been obtained. Carefully transfer the moist Opium to a mortar by means of a spatula, and rub to a smooth paste, then rinse into the original flask with 50 mils of distilled water, agitate it thoroughly and return the whole to the filter. When the liquid has drained off, wash the residue with 75 mils of distilled water. Evaporate the mixed filtrates and washings on a water bath to about 40 Gm. Transfer the extract to a 50 mil graduated flask and wash the evaporating dish with sufficient distilled water to make the entire volume measure exactly 50 mils when cooled to room temperature. Place in a small mortar 4 Gm. of freshly slaked lime (see Reagents, Part III), add about 10 mils of the opium extract and rub to a smooth paste, then add the remainder of the extract and rinse the flask with exactly 10 mils of distilled water, adding the rinsings to the mortar, and stir frequently during fifteen minutes, avoiding unnecessary loss by evaporation. Filter through a dry filter, about 10 cm. in diameter, and transfer exactly 30 mils of the filtrate, representing *four grammes* of Opium, to an Erlenmeyer flask of suitable capacity. To this add 2 mils of alcohol and 15 mils of ether, and, after shaking the mixture, add 1 Gm. of ammonium chloride, stopper the flask and shake

it frequently during half an hour, then set it aside in a cool place for twelve hours or over night. Remove the stopper and brush any adhering crystals back into the flask. Decant the ethereal layer into a small funnel, the neck of which has been previously closed with a pledget of purified cotton. Rinse the flask and contents with 15 mils of ether, and, when the ether has passed through, wash the funnel and cotton with a small quantity of ether, and then pour the aqueous liquid into the funnel without trying to remove the crystals. Wash the crystals in the flask and the contents of the funnel with distilled water, previously saturated with morphine, until the washings are colorless. Then add a few drops of distilled water to replace the morphinated water. Incline the edge of the funnel over the mouth of the flask and by means of a glass rod carefully transfer the cotton with adhering crystals to the flask. Insert the funnel into the neck of the flask and wash the funnel with 20 mils of tenth-normal sulphuric acid V.S., followed by 10 mils of distilled water, applied drop by drop around the edge of the funnel. Remove the funnel, replace the cork, warm gently, and agitate until the crystals are dissolved. Rinse the cork with distilled water and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., cochineal T.S. being used as indicator. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 0.028516 Gm. of anhydrous morphine." *U. S. P. IX.*

Assay of Opium, Br.—"Opium, in No. 50 powder, dried at 60° C. (140° F.), 8 *grammes;* Calcium Hydroxide, freshly prepared, 2 *grammes;* Ammonium Chloride, 2 *grammes;* Alcohol (90 per cent.), Ether, Distilled Water, of each, *a sufficient quantity.* Triturate together the Opium, *calcium hydroxide,* and 20 millilitres of *water,* in a mortar until a uniform mixture results; add 60 millilitres of *water* and stir occasionally during half an hour. To 51 millilitres of the filtered liquid (representing 5 grammes of Opium) in a convenient vessel add 5 millilitres of *alcohol* (90 per cent.), and 25 millilitres of *ether;* shake the mixture; add the *ammonium chloride,* shake well and frequently during half an hour; set aside for twelve hours for the morphine to separate. Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with *ether;* remove the ethereal layer of the liquid in the vessel as completely as possible by means of a small pipette, transferring the liquid to the filter; rinse the vessel with 10 millilitres of *ether,* again transferring the ethereal layer, by means of the pipette, to the filter; wash the filter with a total of 5 millilitres of *ether,* added slowly and in portions. Let the filter dry in the air, and pour upon it the contents of the vessel in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the vessel with *morphinated water,* until the whole has been removed. Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain, and dry it, first at 60° C. (140° F.) and finally, for two hours, at 115° C. (239° F.). Weigh the crystals in the inner filter, counterbalancing by the outer filter. Dissolve 0.2 gramme of the crystals in 10 millilitres of *N/10 solution of sulphuric acid,* and titrate back with *N/10 solution of sodium hydroxide, solution of methyl orange* being used as indicator. Each millilitre of the acid neutralised by the alkaloid corresponds to 0.0285 gramme of pure anhydrous morphine. The weight of pure anhydrous morphine obtained, as indicated by the titration, plus 0.051 gramme, the average loss of morphine during the process, together amount to 0.5 gramme, representing in 100 grammes of the dry powdered Opium 10 grammes of morphine, calculated as anhydrous. *Limit of error* 0.5 gramme in excess or defect." *Br.*

Morphinated Water.—"Prepared by digesting pure morphine in chloroform water for seven days at a temperature of 15.5° C. (60° F.), with shaking occasionally, so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.*

The U. S. and Br. methods of assay are practically identical in principle, belonging to the class of assays known as "lime processes." Experience has proved that the "lime processes" have some objectionable features, depending as they do upon the principle that opium in the presence of lime is treated with a definite quantity of water until the latter has extracted as much as possible of the soluble portions, after which a certain portion of the solution, which is *assumed to represent* a corresponding fraction of the weight of the opium, is weighed or measured off, the morphine determined in it, and the percentage calculated from the quantity found in this fraction or aliquot part. The "lime processes," in the hands of ordinary operators, "register too low," the assay being applied to a proportion of the opium which may or may not be an aliquot part of the whole, but is generally less than it is assumed to be, because no allowance is made for the increase in volume due to the solution of the solid constituents of the opium. The British Pharmacopœia overcomes this objection by requiring 104 mils of liquid to be taken instead of 100 mils. A. B. Stevens has improved the lime method and it is conceded by many that the crystallized morphine by this process is freer from impurities than that obtained by Squibb's method, and that it takes less time to perform the assay than that required for the U. S. P. (8th Rev.) method. The U. S. P. assay of 1890 was based on the method of E. R. Squibb, which requires the complete exhaustion of the sample of opium of its soluble matter, the concentration of this solution, and the determination of the morphine in it. The morphine is separated in a crystal-

line form from its combination with its natural acids in the opium solution, by the addition of the ammonia water; the alcohol present serves to hold up the coloring matter, while the ether facilitates the precipitation of the alkaloidal morphine in crystals, pure morphine requiring 4000 parts of ether for its solution. The U. S. P. VIII assay was also based upon Squibb's method, with the modification of the introduction of a correction factor, *i.e.*, the washing of the morphine crystals with lime water and deducting the weight of the impurities. Want of space prevents our giving a critical review of the other methods of assay in use. (See *U. S. Dispensatory,* 19th ed., p. 905.) Teschemacher and Smith (*Chem. News,* 1888, pp. 93, 103) criticise severely several well known methods of assay, and recommend their own, which does not vary greatly from others in use; indeed, it is difficult to resist the conclusion that the differences in the results arrived at by various operators are largely chargeable to personal error and unfamiliarity with other processes than their own. (See *Ephem.,* June, 1888, 1113; *A. J. P.,* 1887, 74; Prescott's *Organic Analysis,* 1887, 375; Lyon's *Handbook on Assaying Drugs,* 1899, 201; Allen's *Com. Org. Anal.,* vol. iii, Part II, p. 342.)

For other methods of assay, and comments, see *U. S. Dispensatory,* 14th edition, 675, and 15th edition, 1072; *A. J. P.,* 1876, 358; 1878, 184; 1879, 369; 1894, 445; 1897, 244; *N. R.,* Feb., 1880, Dec., 1880, 1881, 174; *West. Drug.,* 1885, 231, also 1886, 442; *Am. Drug.,* 1885, 221, also 1886, 203; Dieterich's method modified by Schlickum, *Ph. Era,* 1887, 325, also 1888, 9; assay adopted by U. S. Laboratory in New York, *Ph. Era,* 1887, 151; *B. C. D.,* 1894, 372; *P. J.,* 1897, 542; *J. I. and E. C.,* 1912, p. 514; *Gehes. Rep.,* 1912; *Year Book of Pharm.,* 1913, 443.

Moerk recommended the treatment of the crystallized morphine with lime water; see U. S. P. VIII assay. (*Proc. Penn. Pharm. Assoc.,* 1897, 65.) Gordin and Prescott propose a volumetric assay based on the estimation of morphine as periodide, after separation by treatment with benzene, acetone, and lime water. (*M. R.,* 1898, 526.) See also *C. D.,* 1898, 20; *D. C.,* 1902, 161; *Ph. Archiv.* 1898, 121; 1901; 1902, 81, 87; *Proc. A. Ph. A.,* 1899, 263; 1902, 425; 1904, 369; *P. J.,* 1903, 909; 1904, 719; *Chem. News,* 1903, 286.

Tests for Opium.—It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and morphine have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence will be afforded of the presence of opium. The test should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substances examined yields a red color with the tincture of ferric chloride, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of lead acetate. If opium be present, there will be a precipitate of lead meconate, and the morphine and lead acetates will remain in solution. The precipitate is then to be suspended in water, and decomposed, either by adding a little diluted sulphuric acid, which forms lead sulphate and leaves the meconic acid in solution, or by passing through it a stream of hydrogen sulphide, removing by filtration the precipitated lead sulphide, and heating the clear liquor, so as to drive off the hydrogen sulphide. With the clear liquor thus obtained, if it contain meconic acid, the tincture of ferric chloride will produce a striking red color, ammoniated copper sulphate a green precipitate, and lead acetate, silver nitrate, and barium chloride, white precipitates soluble in nitric acid. Potassium sulphocyanate, which, according to Wright, is an invariable constituent of saliva (*Simon's Chemistry,* ii, 6), produces a red color with ferric salts, resembling that produced by meconic acid, but, according to Everitt, this color is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red color of iron meconate. (*A. J. P.,* xii, 88.) On the contrary, gold chloride reddens a solution of sulphocyanic acid or a sulphocyanate, but not of meconic acid. Pereira says the acetates also redden ferric salts, but do not afford the results just mentioned with lead acetate and barium chloride. To test for the presence of morphine, the liquid from which the lead meconate has been precipitated, and which may be supposed to contain the morphine and lead acetates, must be freed from the lead by a stream of hydrogen sulphide, and then from the hydrogen sulphide by heat, after which the following reagents may be applied—viz., (1) nitric acid, which colors the morphine red; (2) iodic acid, which is decomposed by the morphine with the extrication of iodine, which colors the liquid reddish-brown, and, if starch is present, unites with it to form a blue compound; (3) solution of ammonia, which, if carefully added, so as not to be in excess, throws down a precipitate of morphine soluble in a great excess of that alkali or of potassium hydroxide; and (4) tannic acid, which precipitates morphine tannate. If the precipitate thrown down by ammonia affords a deep-red color becoming yellow with nitric acid, and a blue color with ferric chloride, the proofs may be considered complete. Merck has proposed a test of opium, founded on the property, which characterizes porphyroxine, of assuming a red color when heated in diluted hydrochloric acid. The suspected liquid is first carefully evaporated, a few drops of solution of potassium hydroxide are added, and the mixture agitated with ether. The ethereal solution being filtered off, a slip of unsized paper is to be dipped into it and dried, and the moistening and drying should be repeated several times. The paper thus prepared is to be moistened with diluted hydrochloric acid, and then exposed to the vapor

of boiling water. If it become reddened, opium may be inferred to exist in the liquid tested. Heusler states that this test is not applicable to the aqueous solution or extract of opium, because porphyroxine is insoluble in water, but Robertson, of Rotterdam, has found it to succeed with the aqueous extract, and infers that the porphyroxine is so combined in opium as to render it in some measure soluble. (*J. P. C.*, 3e sér., xxii.)

Though opium is little injured by time if well kept, yet it does undergo spontaneous change, and Guibourt found less morphine in a specimen which had been in his possession nearly twenty years than it had yielded in its recent state. There was also more coloring matter, due to the darkening by age. (*Ann. Thér.*, 1863, p. 5.)

Among the adulterations of opium, starch has been detected in a specimen examined by J. T. King. The drug was unduly brittle, and evidences of starch were afforded both by the microscope and by iodine. From the size and form of the granules, King inferred that the starch was that of the bean. (*A. J. P.*, Jan., 1869, p. 1.) The probability is that powdered beans were the substance used.

Incompatibles.—The substances which produce precipitates with opium do not all necessarily affect its medicinal virtues, but the *alkalies*, and all vegetable infusions containing *tannic* and *gallic acids*, are incompatible, the former separating and precipitating the free alkaloids, the latter forming with it an insoluble compound.

Uses.—The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates, and it was probably employed before his time.

Opium owes its activity chiefly to the alkaloid morphine and the physiological actions and therapeutic uses of the whole drug are very similar to those of its dominant alkaloid. Sufficient has been said on this subject under *Morphina* (see page 704). Certain of the other alkaloids present in opium differ somewhat in their action from that of morphine, and to a certain extent modify the effects of opium, and we shall therefore consider here the medical properties of some of these secondary alkaloids, and point out the conditions in which opium is preferred to morphine.

The most abundant of the alkaloids after morphine is *narcotine;* indeed, in some varieties of opium it is said to be present in larger quantities than morphine. This alkaloid appears to be almost, if not entirely, free of the characteristic narcotic properties of morphine. In large doses it is a spinal stimulant and produces in the lower animals convulsions. According to Macht (*J. P. Ex. T.*, 1915, xii, p. 339), narcotine differs essentially from morphine in its action upon the respiratory center, acting as a stimulant rather than a depressant. He finds also that because of this antagonistic action upon respiration very much larger doses of morphine can be given if combined with narcotine, without dangerous respiratory depression. It was at one time recommended as an antiperiodic, but is probably of no value; the *dose* employed was from two to three grains (0.13–0.2 Gm.).

Papaverine is the only other alkaloid which occurs naturally in opium in large enough quantity to perceptibly modify the effect of the crude drug. Although much less potent than morphine it possesses distinct narcotic powers. According to Pal (*D. M. W.*, 1914, xl, p. 164) papaverine is an active local anesthetic and is especially valuable because of its power in allaying spasm of the involuntary muscles. Macht (*loc. cit.*) finds that papaverine, like narcotine, antagonizes morphine in its effect upon the respiratory center. Papaverine has been recommended in clinical medicine in *diarrhea*, various forms of *gastric* or *intestinal spasms, asthma*, *biliary colic*, and other conditions of excitability of the involuntary muscles. It, as well as its hydrochloride and sulphate, are recognized by the *N. N. R.*, 1916. The *dose* recommended is usually from one-half to one and one-half grains (0.032–0.096 Gm.), although it is stated that much larger quantities may be given without any evil effects.

Thebaine.—This is chiefly of interest because of its action on the spinal cord. In the lower animals it produces convulsions closely simulating those caused by strychnine. In large quantities it seems to be paralyzant to the peripheral motor nerves. It does not appear to possess narcotic properties.

Codeine being official is considered elsewhere (see page 367). The other alkaloids occur in such small quantities and are mostly of such feeble powers that it is improbable that they play any part in the effects of opium. For further information on the minor alkaloids of opium, see Crawford and Dohme (*Proc. A. Ph. A.*, 1902, p. 472); Leubuscher (*D. M. W.*, 1892); Macht (*J. P. Ex. T.*, 1915, vii, and 1916, viii); and Pal (*D. M. W.*, 1913, xxxix, and 1914, xl).

In a general way it may be said that opium is more constipating and more nauseating in proportion to its narcotic power than is morphine. According to the experiments of Macht, which have received clinical confirmation from the observations of Sahli and others, it would appear that it is also less dangerous because not so depressing to the respiratory center. Why opium should act more powerfully upon the intestinal tract than does morphine is at present not clear; Vamossy (*D. M. W.*, 1897, xxiii) investigated the action of a number of the alkaloids upon the intestines and found that none of them equalled morphine in power. Nevertheless, clinical experience abundantly sustains the statement made above. Although capable of fulfilling all the indications for which morphine is employed, when used as an analgesic or somnifacient, the alkaloid is usually preferred because of its lesser liability to disturb digestion. On the other hand in *diarrhea* and

spasmodic colic the whole drug is superior to the alkaloid. Opium is frequently a valuable remedy in *diabetes mellitus*. How it acts is uncertain, but the whole drug is to be preferred to any of its alkaloids. Because of its peculiar power in dilating the vessels of the skin opium tends to increase the sweat and is therefore useful in minor infections, such as *colds, grippe, muscular rheumatism,* and the like. As a sudorific it is generally combined with ipecac in the form of Dover's Powder.

Opium is largely used locally in the form of its tincture either in combination with a solution of lead subacetate or by itself. While it possesses feeble counterirritant and anesthetic powers the freedom with which it is used as a local application verges on the superstitious.

Poisoning.—In moderately large doses opium produces, generally, a pleasurable feeling of languor followed by drowsiness. In toxic dose the most prominent symptom is sleep, from which, in the moderate degrees of poisoning, the patient can easily be awakened by loud noises, shaking, etc. At this stage of the poisoning the respirations are generally slower than normal but of good depth, the pulse is slow and full, the skin warm and flushed and moist, the pupil contracted. As the intoxication deepens the respirations become slower and shallower and often irregular, and the skin is frequently more or less cyanotic from imperfect aeration of the blood; the pupils grow smaller and are eventually reduced in size to almost complete invisibility; the patient can be aroused only with difficulty and when left to himself immediately sinks back into a comatose sleep. The reflexes are generally not greatly affected. When the dose has been very large there may develop, late in the poisoning, failure of the circulation with rapid, feeble pulse and cold, clammy, cyanotic skin. The quantity required to take life varies enormously according to the individual susceptibility of the patient. On the one hand, several fatalities have been reported from less than one-half a grain of morphine and from four or five grains of opium. On the other hand, we have seen an opium habitué take 8 grains of morphine at a dose with no serious effect, and Fell has reported recovery following 33 grains of morphine.

Treatment of Opium Poisoning.—For the evacuation of the stomach, unless the drug has been taken in solid form, the stomach tube is preferable to emetics, the latter often failing to act because of the effect of the drug upon the vomiting center. In the absence of a stomach tube, however, twenty or thirty grains of zinc sulphate may be given as an emetic. The best chemical antidote is potassium permanganate, which oxidizes the active principle of the drug to a harmless compound; four or five grains of the permanganate may be given at a dose. Where the stomach tube is employed it is well to wash out the stomach with a 1 to 500 solution of potassium permanganate leaving 3 or 4 ounces of this solution in the stomach to neutralize any alkaloid which may be later excreted. If this antidote be not at hand tannic acid may be used as a partial but less satisfactory antidote; it is well to follow this with a saline cathartic as the tannate of morphine is slowly absorbable. Fantus has obtained favorable results in experimental morphine poisoning with the use of Fuller's earth (see *Terra Silicea Purificata*). Aside from the prevention of absorption, the most important measures are those directed towards maintaining respiratory function. As this is always in abeyance during sleep the patient should, if possible, be kept awake. Many of the measures, however, which have been employed for preventing sleep have done as much harm in exhausting the patient's strength as the wakefulness has done good. By far the best means for this purpose is the faradic battery, using either a brush electrode or a bare metal upon the skin; with this apparatus an exquisite pain can be caused without any injury to the body. Slapping the skin with the fringe of a wet towel is also useful, but care must be exercised not to bruise. Alternate dashes of hot 40.5° C. (105° F.) and cold water 10° C. (50° F.) upon the bare chest may also be of service. Occasionally by repeated shouting the patient may be kept from going to sleep. We do not believe that the advice, so often given, to keep the patient constantly walking is sound. Among the respiratory stimulants the most useful is probably cocaine or strychnine; caffeine and atropine are also of much service. There was at one time a wide-spread belief that atropine was a complete physiological antagonist to morphine. This, however, is erroneous; while the drug may be useful for its stimulating effects upon the respiratory center, it must be remembered that large doses of atropine are depressant, and if used too freely may injure rather than benefit. If, despite these measures, respiration remains dangerously insufficient, recourse should be had to artificial respiration either by the Sylvester or Schaefer method, or preferably with one of the apparatuses for forced artificial respiration, such as the pulmotor. By means of a simple bellows apparatus Fell (*Medical Examiner,* June, 1899) succeeded in maintaining life for seventy-three hours with the eventual recovery of the patient. The intravenous injection of salt solution has also been recommended with the idea of diluting the poison in the blood. Cardiac stimulants, as ammonia, may occasionally be required in severe cases.

Opium Smoking.—By the various nations of the Orient opium is employed as an intoxicant by smoking in two ways. In Turkey and its neighboring countries it is placed upon tobacco, in a small pipe. In the East it is usually made into a very thick, almost plastic, liquid, and a drop of it is held over the flame of a small oil-lamp, and the resulting fumes inhaled through pipes of various forms. In China, opium is prepared for smoking by mixing it with various ingredients to give form and flavor. It occurs

as a soft blackish paste and contains less than 9 per cent. of morphine. The importation of smoking opium is forbidden in the United States. For an elaborate study of the chemistry of the opiums used for smoking in various countries, see *Ap. Ztg.*, 1903.

Moissan has found in opium smoke, morphine, pyrrol, pyridine with various homologues, acetone, and various hydropyridine bases, all of which are physiologically active. This analysis has been confirmed by Hartwich and Simon, who believe that the activity of the opium smoke depends not so much upon the morphine as upon the other products of the destructive distillation.

Dose, from one to two grains (0.065–0.13 Gm.).

OPIUM DEODORATUM. U. S.

DEODORIZED OPIUM Opium Deod.

(ō′pĭ-ŭm dē-ō-dō-rā′tŭm)

"Deodorized Opium yields not less than 10 per cent. nor more than 10.5 per cent. of anhydrous morphine. Deodorized Opium of a higher morphine percentage may be brought within the required limits by admixture with deodorized opium of a lower percentage or with some inert diluent. Preserve it in well-closed containers." *U. S.*

Opium Denarcotisatum, *U. S.* 1880; Denarcotized Opium.

* "Powdered Opium, *five hundred grammes* [or 17 ounces av., 279 grains]; Purified Petroleum Benzin, *a sufficient quantity.* Macerate the powdered opium for twenty-four hours in a wide-mouthed, well-closed bottle with sufficient purified petroleum benzin to cover it completely, shaking the mixture occasionally. Then decant the clear benzin layer as closely as possible and repeat the maceration for twenty-four hours with another portion of purified petroleum benzin. Again decant the clear benzin layer and transfer the remaining contents of the bottle to a plain filter. Closely cover the funnel, allow the mixture to drain and then slowly percolate the residue with purified petroleum benzin until the latter passes through without color. Remove the filter containing the Opium from the funnel, expose the powder to the open air, so that it may dry thoroughly, and add sufficient sugar of milk to restore the original weight. Care should be used to guard against the danger due to the inflammability of the benzin. Granulated opium may also be deodorized in the manner directed above.

"**Assay.**—Proceed as directed under *Opium.*" *U. S.*

The use of purified petroleum benzin (in place of ether) in the U. S. P. VIII and IX process is an improvement. The use of benzin has often been proposed by Ebert and others, but the objection has always been that it was difficult to obtain it of sufficient purity.

This preparation represents the medicinal properties of opium without the presence of the odorous principles, which are believed by many physicians to play an important part in the nausea and depression produced in some people by opium.

Dose, one to two grains (0.065–0.13 Gm.).

OPIUM GRANULATUM. U. S.

GRANULATED OPIUM Opium Gran.

(ō′pĭ-ŭm grăn-ū-lā′tŭm)

"Opium dried at a temperature not exceeding 70° C. (158° F.) reduced to a coarse (No. 8 to No. 20) powder and yielding not less than 10 per cent. nor more than 10.5 per cent. of anhydrous morphine. Granulated Opium of a higher morphine percentage may be brought within the required limits of strength by admixture with granulated opium of a lower percentage, or with some inert diluent. Preserve it in well-closed containers.

"**Assay.**—Proceed as directed under *Opium.*" *U. S.*

This form of opium was introduced into the U. S. P. because, on account of its being in coarse powder, it is better fitted for use in making the liquid preparations of opium. (See *Opium.*)

Dose, one to two grains (0.065–0.13 Gm.).

OXYGENIUM. U. S.

OXYGEN Oxygen.

(ǫx-ў-ǧēn'ị-ŭm)

"It contains not less than 95 per cent. by volume of O(16). For convenience it is usually compressed in metal cylinders." *U. S.*

Oxygen was discovered about 1774 almost simultaneously by Priestley and Scheele. Both evolved it from metallic oxides or calces as they were called. Priestley called it *dephlogisticated air,* and Scheele called it *fire air,* it not then being recognized as a gaseous element, but was thought to be a kind of air. It is the most abundant of the elemental substances constituting, according to the calculations of some authorities, one-half of the weight of the earth and its atmosphere.

For experimental and laboratory purposes it is usually prepared by heating a mixture of potassium chlorate and manganese dioxide, the latter substance acting as a catalyst and remaining unchanged at the end of the operation, possessing the property of allowing the reaction $KClO_3 = KCl + O_3$ to take place at lower temperatures and without danger. Industrially it is usually prepared by the continuous process known as Brin's, in which BaO is heated in porcelain tubes to 500° C. (932° F.) in a current of carbon dioxide free air. This produces BaO_2, which upon further heating to 800° C. (1472° F.) again evolves the oxygen ($BaO_2 = BaO + O$). Upon lowering the temperature to 500° C. (932° F.) the absorption of oxygen again occurs and the alternate absorption and liberation may be repeated indefinitely, or until as is found in practice, the barium oxide loses its activity. Oxygen is also produced commercially from liquid air, taking advantage of the facts that the nitrogen is more volatile, and that the oxygen has a tendency to liquefy first.

G. Kassner has described a method for producing oxygen from the air by the use of a mixture of *sodium metaplumbate,* Na_2PbO_3, and *sodium manganate,* Na_2MnO_4. This combination, which is emerald-green in color, he calls *plumboxan.* The mixture is placed in a combustion tube and heated to between 430° C. and 450° C. (806° and 842° F.). Air freed from CO_2 is then passed through it and the oxygen is absorbed by the plumboxan while pure nitrogen passes through unchanged. Steam is then passed into the mass, which liberates the oxygen in an exceedingly pure condition. By alternately injecting air and steam, nitrogen and oxygen can be evolved in the order given indefinitely. The reaction, as given by the author, to account for the changes, are very complex. (*A. Pharm.,* ccli, 251, p. 596.)

Oxygen has also been produced commercially by heating sodium permanganate or by liberating it from sodium peroxide by the action of water. Oxygen comes into commerce for laboratory or medicinal purposes compressed into steel cylinders.

"Oxygen is a colorless, odorless, and tasteless gas. It supports combustion more readily than air; a glowing splinter of wood held in the gas bursts into flame. One volume of Oxygen dissolves in about 34 volumes of water and in about 3.6 volumes of alcohol at 25° C. (77° F.). Pass 2000 mils of Oxygen, measured under normal atmospheric pressure at about 25° C. (77° F.), at a rate not exceeding 4000 mils per hour, through 100 mils of barium hydroxide T.S.; not more than an opalescent turbidity is produced (*carbon dioxide*). Pass 2000 mils of Oxygen, under the conditions described above, through a mixture of distilled water and 1 mil of silver nitrate T.S.; no opalescence is produced (*halogens*). Pass 2000 mils of Oxygen through 100 mils of distilled water, colored with a few drops of litmus T.S., under the conditions described above; the color of the liquid is not changed (*acids or bases*).

"**Assay.**—Mix about 50 mils of Oxygen, accurately measured in a calibrated tube, with 10 mils of alkaline pyrogallol T.S.; not less than 95 per cent. by volume is absorbed, corresponding to not less than 95 per cent. by volume of O." *U. S.*

Uses.—Pure oxygen is so irritant locally that it is difficult to respire it; the statements sometimes made, however, that it is impossible to live in an atmosphere of pure oxygen do not seem to be well supported, at least as far as human beings are concerned. In normal health it is doubtful whether the respiring of pure oxygen has any marked effect upon the bodily processes except that which is due to the irritation of the mucous membrane. It must be remembered that the oxygen-carrying power of the blood is due to the chemical change of hemoglobin in the corpuscles, and enough oxygen is, ordinarily, absorbed by the lungs from the atmosphere to fully oxidize the hemoglobin, so that the blood leaving the lungs contains almost entirely oxyhemoglobin. The only increase in the amount of oxygen the blood will carry is in the relatively small proportion which is dissolved in the blood plasma. While this quantity may be notably increased by inhaling oxygen, in conditions of health its proportion to the oxygen in oxyhemoglobin is so small that it does not greatly affect oxidative processes in the body. On the other hand when the oxygen-carrying power of the blood is reduced—as, for instance, in *carbon monoxide poisoning* or *nitrite poisoning*—through chemical change in the hemoglobin the amount of oxygen which may be dissolved by the plasma becomes a matter of practical importance and Haldane has experimentally shown (*J. P.,* 1897, xxi, p. 160) that animals will survive a supra-fatal dose of nitrites in an atmosphere of pure oxygen. Again in cyanotic conditions due to insufficiency of the circulation, as in cases of *heart failure,* the small increase in the oxygen of the blood may be sufficient to supply the needs of the body and clinical improvement is often seen from the use of oxygen in such instances. In cases

where the passage of air in and out of the lungs is obstructed, as in *asthma* or *pneumonia*, the use of oxygen is still more rational because of the small amount of air which comes in contact with the blood. Therefore in practically all cases in which cyanosis indicates a deficient amount of oxygen being carried by the blood, the inhalation of this gas is a reasonable procedure and clinically has in many cases given great relief. It must be remembered, however, that the oxygen does not act by stimulating any vital function, in the sense that strychnine or ammonium might, but it merely supplies a deficient necessity of life. The custom of having a patient inhale oxygen for ten or fifteen minutes at a time three or four times a day, is foolish; the inhalation of the gas must be kept up more or less continuously as long as the symptoms indicate the need of it.

OXYMEL. Br.

OXYMEL

(ŏx'y-mĕl)

"Acetic Acid, 100 *millilitres;* Distilled Water, 100 *millilitres;* Purified Honey, 500 *millilitres.* Mix." *Br.*

Oxymel Simplex; Mel Acetatum, Mellite de Vinaigre, *Fr. Cod.;* Oxymelite simple, Acétomel, *Fr.;* Sauerhonig, *G.;* Oximiel simple, *Sp.*

"Specific gravity 1.27. 25 grammes require for neutralisation not less than 32 millilitres of *N/2 solution of sodium hydroxide.* The liquid obtained by mixing 25 grammes of Oxymel with 1 millilitre of *solution of lead subacetate,* diluting to 100 millilitres with *water,* adding 1 gramme of *animal charcoal,* and filtering until bright, has an *optical rotation* at 15.5° C. (60° F.) of not more than –3.9° in a tube 200 millimetres long." *Br.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines and to impart flavor to drinks in febrile diseases.

Dose, from one to two fluidrachms (3.75–7.5 mils).

OXYMEL SCILLÆ. Br.

OXYMEL OF SQUILL

(ŏx'y-mĕl sçĭl'læ)

"Vinegar of Squill, 200 *millilitres;* Purified Honey, 500 *millilitres.* Mix." *Br.*

Mellite de Vinaigre Scillitique, Oxymel Scillitique, *Fr. Cod.;* Oxymel Scillæ, *P. G.;* Meerzwiebelhonig, *G.;* Ossimiele scillitico, *It.;* Oximiel escilítico, *Sp.*

"Specific gravity 1.29. 25 grammes require for neutralisation not less than 11.9 millilitres of *N/2 solution of sodium hydroxide.* The liquid obtained by mixing 25 grammes of Oxymel of Squill with 1 millilitre of *solution of lead subacetate,* diluting to 100 millilitres with *water,* adding 1 gramme of *animal charcoal,* and filtering until bright, has an *optical rotation* at 15.5° C. (60° F.) of not more than –3.9° in a tube 200 millimetres long." *Br.*

After a long vogue, this preparation fell into such neglect that it was abandoned by the Pharmacopœias. Its reintroduction, however, into the Br. Pharmacopœia indicates that it is still prescribed; it has also been introduced into the N. F. IV (see Part III). It has the virtues of syrup of squill, but no advantages. It is chiefly used as an expectorant in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration.

Dose, from one-half to one fluidrachm (1.8–3.75 mils). In large doses it is emetic, and as such is sometimes used in *infantile croup.*

OXYMEL URGINEÆ. Br.

OXYMEL OF URGINEA [Oxymel of Indian Squill]

(ŏx'y-mĕl ŭr-gĭ'nē-æ)

"Vinegar of Urginea, 200 *millilitres;* Purified Honey, 500 *millilitres.* Mix." *Br.*

"Specific gravity 1.29. 25 grammes require for neutralisation not less than 11.9 millilitres of *N/2 solution of sodium hydroxide.* The liquid obtained by mixing 25 grammes of Oxymel of Urginea with 1 millilitre of *solution of lead subacetate,* diluting to 100 millilitres with *water,* adding 1 gramme of *animal charcoal,* and filtering until bright, has an *optical rotation* at 15.5° C. (60° F.) of not more than –3.9° in a tube 200 millilitres long." *Br.*

This is a new preparation of the British Pharmacopœia, 1914. It is used for the same purposes as the *oxymel scillæ.*

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

PANCREATINUM. U. S.

PANCREATIN Pancreat.

(păn-crē-ą-tĭ'nŭm)

"It contains enzymes, consisting principally of amylopsin, trypsin, and steapsin, found in the pancreas of warm-blooded animals, and obtained from the fresh pancreas of the hog (*Sus scrofa* var. *domesticus* Gray) (Fam. *Suidæ*), or of the ox (*Bos taurus* Linné) (Fam. *Bovidæ*). It converts not less than 25 times its own weight of starch into soluble carbohydrates when assayed as directed on page 826. Pancreatin of a higher digestive power may be brought to this standard by admixture with sugar of milk. Preserve it in well-closed containers." *U. S.*

Pancréatine médicinale, Pancreatina, *Fr. Cod.;* Pancreatina, *Sp.*

The term "pancreatin" has been variously used for many different preparations from the pancreatic gland, and has long been popularly employed for the purpose of distinguishing preparations more or less of the nature of extracts made from the gland. The *pancreatic juice* is an albuminous, transparent liquid, odorless, alkaline, and containing about eight per cent. of organic matter. It is now generally

recognized that there are present in the pancreatin secretion three distinct enzymes: *trypsin*, whose function it is to convert albuminous matters into peptone, and probably also peptones into their aminoacids; *amylopsin* or *amylase*, a ferment closely allied if not identical with the ptyalin of the saliva, which hydralizes starch into maltose and dextrin; and *steapsin* (*lipase*), which has the power of splitting up fats into glycerin and fatty acids. Besides these ferments there is apparently present also another substance which has the property of curdling milk. Because of its fat splitting properties the pancreatic juice has a strong emulsifying effect, the viscous agent being the soap formed through the splitting of the fat. The activity of the lipase is greatly increased by the presence of bile. This emulsifying action takes place very rapidly; according to Rachford (*J. Chem. S.*, 1891, 948) a spontaneous emulsion may be formed in two minutes at room temperature.

All of the pancreatic ferments are active in neutral or mildly alkaline media, but the most favorable reaction is not the same for all of them, thus trypsin is best with an alkalinity corresponding to about 1 per cent. of sodium carbonate, but amylopsin acts most rapidly in the presence of 0.01 per cent. of hydrochloric acid, and the action of the fat splitting ferment is also accelerated by a faintly acid reaction.

The pancreatin of the U. S. Pharmacopœia is composed of all these ferments, with more or less extraneous matter. It is officially described as "a cream-colored, amorphous powder, having a faint, characteristic, but not offensive odor. It is slowly and incompletely soluble in water; insoluble in alcohol. Pancreatin changes proteins into proteoses and derived substances, and converts starch into dextrins and sugars. Its peculiar activities are best exhibited in neutral or faintly alkaline media; more than traces of mineral acids or large amounts of alkali hydroxides render it inert. An excess of alkali carbonates also inhibits its action. Introduce 2 Gm. of Pancreatin into a flask of about 50 mils capacity, add 20 mils of ether, stopper and set it aside for several hours, shaking by rotating at frequent intervals. Decant the supernatant ether, by means of a guiding rod, into a plain filter of about 7 cm. diameter, previously moistened with ether, and collect the filtrate in a tared beaker. To the residue remaining in the flask add a further portion of 10 mils of ether, proceeding as directed before, then a third portion of 10 mils of ether and transfer the ether and the remainder of the pancreatin to the filter. Allow the filter and contents to drain, then allow the ether to evaporate spontaneously and dry the beaker and residue to constant weight at 100° C. (212° F.). The residue weighs not more than 0.06 Gm. (*fat*). Add 0.28 Gm. of Pancreatin and 1.5 Gm. of sodium bicarbonate to 100 mils of tepid distilled water contained in a flask, then add 400 mils of fresh milk which has previously been heated to 40° C. (104° F.), and maintain the temperature of the mixture at this point for thirty minutes. At the end of this time the milk is so completely peptonized that on diluting 3 mils with 9 mils of distilled water and then mixing with 3 mils of acetic acid no coagulation occurs." *U. S.*

R. H. Jones found commercial pancreatin unable to withstand the U. S. P. 1890 tests, which he stated were too stringent; he suggested the addition of a starch digestion test. (*P. J.*, 1896, 194.) (See official assay of pancreatin.)

Various methods of manufacturing pancreatic extracts are employed. Water readily dissolves all the ferments and the French Codex directs that pancreas gland purified by separating foreign matter is to be cut into small pieces, macerated in chloroform water, then expressed, the liquid filtered and rapidly evaporated at a temperature not exceeding 45° C. (113° F.). Choay (*P. J.*, 1898, 505) criticizes the temperature for evaporation and recommends evaporation *in vacuo* at 38° C. (100.4° F.). Biernacki (*A. J. P.*, 1892) previously stated that digestive ferments require for their efficient action a temperature little over that of the human body, 39° C. (102.2° F.). The process described by R. V. Mattison, based on the method of Scheffer for obtaining pepsin, is as follows: Macerate the cut-up pancreas in water acidulated with hydrochloric acid for forty-eight hours; filter until clear. Add a saturated solution of sodium chloride, and allow to stand until pancreatin rises to the top; skim this, drain on a muslin filter, wash with a less concentrated solution of salt, and press until nearly dry; then rub up with sugar of milk, dry thoroughly, without heat, and dilute with sugar of milk until ten grains just emulsify two drachms of cod liver oil. The mixed pancreatic enzymes may be extracted from the gland by means of glycerin, and such an extract may be preserved indefinitely. A useful and permanent extract may also be obtained by exhausting the finely divided pancreas with water containing about 2 per cent. of boric acid and 1 per cent. of borax. (Allen, *Com. Org. Anal.*, 2d ed., vol. iv, 354.) The mixed pancreatic enzymes may also be extracted by means of glycerin which gives an active extract which may be preserved indefinitely, but one which cannot be reduced to the dry state. For this purpose the gland is finely minced, rubbed up with some clean sand, shaken with from 10 to 20 parts of glycerin and allowed to stand for about two weeks, then filtered. Another method of extracting its activity is by macerating the minced gland with four times its weight of 25 per cent. alcohol for four or five days. If the pancreas be allowed to stand for two or three days before extracting the resulting pancreatin will be richer in the trypsin and amylopsin, but will have very little fat splitting powers. Where it is desirable to make a pancreatin containing active lipase it should be made from the fresh gland.

As the amount of digestive ferment secreted by the pancreas varies greatly according to the time since feeding, it is manifest that pancreatic extract will contain more or less of the enzymes according to the time of the animal's death, and that the commercial pancreatin must consequently vary greatly in strength. As the power of pancreatin cannot be judged accurately by its physical appearance it is very important to have some test which will rigidly decide as to its value. If pancreatin be added to fresh milk without an alkali, in the course of a few minutes the liquid acquires the property of curdling abundantly upon boiling, and Wm. Roberts (*Digestive Ferments*, London, 1881) estimates the value of a pancreatin by the number of mils of milk which are transformed by one mil of the sample at a temperature of 40° C. (104° F.) to the curdling point in five minutes. (See *Liquor Pancreatis*, p. 650.)

A method of determining the value of pancreatin has been made official and is as follows:

Assay of Pancreatin. U. S. P. IX.—"Shake 10 Gm. or more of powdered potato starch (see Part II) with about 10 times its weight of cold distilled water, and, after draining the mixture on a filter, wash it with the same quantity of distilled water. Place the washed starch at once in an air bath and maintain a temperature of about 50° C. (122° F.) until the starch is sensibly dry. Reduce it to a fine powder and place it in a well-stoppered bottle. Determine the percentage of water still remaining in the starch by drying about 0.5 Gm. of it in an air bath, gradually raising the temperature to 120° C. (248° F.), and maintaining it at that temperature for four hours. Of the washed and partially dried starch, mix a quantity equivalent to 7.5 Gm. of dry starch in a 400 mil beaker with 10 mils of cold distilled water, add 190 mils of boiling distilled water and boil the mixture gently (for approximately five minutes) with constant stirring until a translucent uniform paste is obtained. Replace the water lost by evaporation and cool the paste to 40° C. (104° F.) in a water bath previously adjusted to this temperature and add a solution of 0.3 Gm. of Pancreatin in 10 mils of distilled water, just previously made at 40° C. (104° F.). Mix well and maintain the same temperature for exactly five minutes, when a thin, nearly clear liquid is produced. At once add 0.1 mil of this liquid to a previously made mixture of 0.2 mil of tenth-normal iodine V.S. and 60 mils of distilled water; no blue, red, or violet color is produced." *U. S.*

Uses.—Pancreatin was first used in medicine on account of its emulsifying properties. Horace Dobell, noticing that consumptives are very likely to have a dislike for fat, conceived the idea that this was due to lack of pancreatic digestion, and administered an emulsion made with the fat of beef stirred in milk with the pancreatic juice of the pig. A little later, pancreatic preparations of cod liver oil were prepared, and still have much vogue. Besides this employment, pancreatin has two distinct uses; first, as a ferment to be administered in dyspepsia; second, as a valuable means for the predigestion of food. As pancreatin acts in an alkaline solution and pepsin in an acid one, it would seem *a priori* not probable that pancreatin given by the stomach would be of avail in cases of feeble digestion. Nevertheless, as the experiments of Schweitzer, which have been confirmed by Gross, seem to show, some hours' digestion is necessary for the pancreatin to be destroyed by acid solutions. It is therefore probable that when given internally pancreatin may escape from the stomach into the intestines and the combination of pepsin and pancreatin in *dyspepsia* is not unphilosophical. In the predigestion of food by pancreatin, five grains of commercial pancreatin of good quality, with twenty grains of sodium bicarbonate, in an ounce of warm water, may be added to a pint of milk, and kept at the temperature of 43.3° C. (110° F.) for from twenty minutes to an hour. As the thoroughly peptonized or pre-digested food is very bitter, when the milk is to be given by the mouth it is better to arrest the peptonizing process by boiling the milk after digestion has continued for twenty to thirty minutes, unless the milk can be used at once. For receipts for preparing various peptonized foods, see H. C. Wood's *Therapeutics*. Nutritive enema should be thoroughly pancreatized.

Trypsin has been used in medicine in a variety of conditions. Beer (*Lancet*, 1905) has recommended it as a local treatment for *inoperable cancers*, Schiller (*K. T. W.*, 1910) in the treatment of *tuberculous abscesses*, and Lamballe (*N. Y. M. R.*, 1913) asserts that the intramuscular injection of solutions of trypsin have curative value in *malaria*.

Dose, of pancreatin, eight to fifteen grains (0.5–1.0 Gm.).

PARAFFINUM. U. S. (Br.)

PARAFFIN Paraff.

(păr-ăf-fī'nŭm)

"A purified mixture of solid hydrocarbons, usually obtained from petroleum." *U. S.* "Hard Paraffin is a mixture of solid hydrocarbons." *Br.*

Paraffinum Durum, *Br.*, Hard Paraffin; Paraffin Wax; Solid Paraffin; Paraffine, *Fr. Cod.;* Paraffinum solidum, *P. G.;* Festes Paraffin, Gereinigtes Erdwachs, *G.;* Parafina, *Sp.*

The name *paraffin*, often spelled *paraffine*, was originally bestowed by Baron von Reichenbach upon a waxy substance obtained through the destructive distillation of wood. He derived it from *parum affinis*, and thus intended to indicate its very neutral character. The name is now popularly applied to a solid white diaphanous substance, resembling white wax, which is procured from petroleum or bituminous shales by distillation, or from ozokerite by puri-

fication. (See *Ozokerite, Ceresin,* in Part II.) In the manufacture from petroleum, as carried out in the United States, the residuum from the distillation of crude petroleum for illuminating oil is taken. This is redistilled from what are called "tar stills," in which the distillation is pushed until only coke remains. The paraffin oil distillate obtained in this way is treated with from 4 to 5 per cent. of sulphuric acid, washed, and treated with caustic soda, the mixture being kept liquid by the aid of steam coils. After settling, the paraffin oil goes to the "chill-rooms," where, by the aid of the ammonia refrigerating machines and the circulation of cooled brine, the whole mass is brought to a semisolid condition. This is subjected to powerful pressure, and the refined heavy oil which drains off is collected as lubricating oil. Its specific gravity should be about 32° B. The press cake may be broken up, melted, and allowed to solidify, and then submitted to still greater pressure at a higher temperature 21.1° C. (70° F.) than before, when the product is known as "refined wax." To convert it into block paraffin it must be washed with petroleum benzin, pressed, melted, and filtered through bone black or other medium, when it solidifies in a hard, translucent, colorless condition.

Properties.—Paraffin, in its pure condition, is a white, waxy, inodorous, tasteless substance, harder than tallow, softer than wax, with a specific gravity of 0.900. Its melting point is variable, depending somewhat upon its origin. It ranges between 43° and 65° C. (109.4° and 149° F.). An ultimate analysis yields, on the average, carbon 85 per cent. and hydrogen 15 per cent. It is insoluble in water, is indifferent to the most powerful acids, alkalies, and chlorine, and can be distilled unchanged with strong oil of vitriol. Warm alcohol, ether, oil of turpentine, olive oil, benzene, chloroform, and carbon disulphide dissolve it readily. It can be mixed in all proportions with wax, stearin, palmitin, and resin. As stearin is less soluble in benzene than paraffin, Vogel proposes this reaction as a method for detecting the adulteration of paraffin with stearin. (Joy.) It is officially described as "a colorless, or white, more or less translucent mass, crystalline when separating from solution, without odor or taste, and slightly greasy to the touch. It is insoluble in water or alcohol; slightly soluble in dehydrated alcohol, freely soluble in ether, petroleum benzin, benzene, carbon disulphide, volatile oils, or in most warm fixed oils. Specific gravity: about 0.900 at 25° C. (77° F.). It melts between 50° and 57° C. (122° and 134.6° F.). When strongly heated, it ignites, burns with a luminous flame, and deposits carbon. Heat about 0.5 Gm. of Paraffin in a dry test tube with an equal weight of sulphur; the mixture becomes black from separated carbon, and hydrogen sulphide gas is evolved. Paraffin is not acted upon or colored by concentrated sulphuric acid or nitric acid in the cold. Shake melted Paraffin with an equal volume of hot alcohol; the separated alcohol does not redden moistened blue litmus paper (*acids*)." *U. S.*

The Br. Pharm. describes it as "colorless, crystalline, more or less translucent; wax-like, slightly greasy to the touch. No odor or taste. Melting point 50° to 60° C. (122°–140° F.). 5 millilitres of *alcohol* (90 per cent.) shaken with 5 grammes of the melted Paraffin are not acid to *litmus*. 5 grammes, when heated, burn with a luminous flame, leaving no appreciable ash." *Br.*

The fact that solid paraffin wax is essentially made up of a mixture of hydrocarbons of the series C_nH_{2n+2} was established by Gill and Meusel, who studied the action of bromine upon it. The fact that when paraffin wax is oxidized by concentrated nitric acid or by chromium trioxide mixture we obtain *paraffinic acid,* $C_{24}H_{48}O_2$, and *cerotic acid,* $C_{27}H_{54}O_2$, shows that it is essentially made up of hydrocarbons between $C_{24}H_{50}$ and $C_{27}H_{56}$. For *Soft Paraffin,* or *Paraffinum Molle,* see *Petrolatum,* p. 922.

It would be beyond the scope of this work to give all the uses of this very valuable substance. In the arts paraffin is used for many purposes, especially in the manufacture of candles, and sealing various vessels to exclude air. Lemons and eggs coated with paraffin may be kept for long periods of time without decomposition. It is also valuable to saturate paper, rendering it impervious to moisture. In pharmacy it is used chiefly to give stiffness to ointments. It was at one time employed in cosmetic surgery by injecting melted paraffin for filling out undesirable hollows. The treatment resulted in a number of cases, however, in extensive sloughing and has been largely abandoned.

PARAFORMALDEHYDUM. U. S.

PARAFORMALDEHYDE Paraform. [Paraform, Trioxymethylene, Triformal]

(păr-ă-fôr-măl-dē-hȳ′dŭm)

"It contains not less than 95 per cent. of $(HCHO)_3$ (90.05), a polymeric form of formaldehyde. Preserve it in well-closed containers in a cool place, protected from light." *U. S.*

Paraformaldehyde is always produced to a greater or lesser extent when solutions of formaldehyde are allowed to evaporate. The change from the ordinary into the polymeric form also takes place at low temperatures, especially when the solution is free from methyl alcohol. This is the way in which it is now produced commercially.

"Paraformaldehyde occurs in white, friable masses, or as a powder, having a slight odor of formaldehyde. On heating it is partly converted into formaldehyde and partly sublimed unchanged. It is slowly soluble in cold water, more readily soluble in hot water with the formation of formaldehyde; insoluble in alcohol or ether; soluble in fixed alkali solutions. A mixture of about 0.01 Gm. each of Paraformalde-

hyde and morphine sulphate and 10 drops of sulphuric acid assumes a violet-red color, changing to blue. Incinerate about 2 Gm. Paraformaldehyde; not more than 0.1 per cent. of ash remains. Shake about 0.5 Gm. of Paraformaldehyde, finely powdered, with 10 mils of distilled water; the latter remains neutral to litmus.

"**Assay.**—Mix about 1 Gm. of Paraformaldehyde, finely powdered and accurately weighed, with 50 mils of normal potassium hydroxide V.S. in a 250 mil flask, and add immediately, but slowly, through a small funnel, 50 mils of solution of hydrogen dioxide which has been previously rendered neutral to litmus with sodium hydroxide. When the reaction has ceased and the foam subsided, rinse the funnel and the sides of the flask with distilled water, allow the liquid to stand for half an hour and then determine the excess of alkali with normal sulphuric acid V.S., using litmus T.S. as indicator. It shows not less than 95 per cent. of $(HCHO)_3$.

"Each mil of normal potassium hydroxide V.S. corresponds to 0.03002 Gm. of $(HCHO)_3$. Each gramme of Paraformaldehyde corresponds to not less than 31.6 mils of normal potassium hydroxide V.S." *U. S.*

Uses.—Although trioxymethylene appears to possess some antibacterial properties *per se*, it is used chiefly as a source for the generation of formaldehyde. The especial utility of the substance for this purpose lies in the fact that by simply heating it is converted into the active gas. Special lamps are upon the market in which a small alcohol flame serves to at once depolymerize the paraform while the moisture from the combustion of the alcohol increases the activity of the formaldehyde. Rideal (*Disinfection and the Preservation of Food*, 1903, p. 309) finds that 10 Gm. of paraformaldehyde per thousand cubic feet of air space in a properly sealed room, is sufficient to destroy the vitality of most pathogenic organisms, but will not certainly kill those enclosed in bedding or similarly protected. The room should be left closed for twenty-four hours. Because of the comparative cost, however, this method is not to be recommended for disinfection of large spaces, but is very convenient for the sterilization of various surgical materials which might be injured by boiling. For this purpose small air-tight chambers are employed in which from 1 to 2 Gm. (15–30 grains) for each cubic yard of air space is evaporated.

Paraformaldehyde is also occasionally used internally as a gastro-intestinal disinfectant. Pauchet and Sourdat (*B. A. M.*, 1914) highly laud gauze impregnated with paraform for the treatment of gunshot and other *wounds*. For the preparation of this the gauze is placed in a tin box with a few tablets of trioxymethylene and the box closed, and then put in a warm place, about 50° C. (122° F.) for an hour. It is also used externally as a caustic, for the destruction of warts, in 10 per cent. solution.

***Dose*, five to fifteen grains (0.3–1.0 Gm.)**

PARALDEHYDUM. U. S., Br.

PARALDEHYDE Paraldehyd.

(pa-răl-dē-hī'dŭm)

"A polymer $[(CH_3CHO)_3 = 132.10]$ of acetaldehyde. Preserve it in well-closed containers, in a cool place, protected from light." *U. S.*

"Paraldehyde, $C_6H_{12}O_3$, is a product of the polymerisation of acetaldehyde." *Br.*

Paraldéhyde, Elaldéhyde, *Fr. Cod.*; Paraldehydum, *P. G.*; Paraldehyd, *G.*; Paraldehido, *Sp.*

Small quantities of acids like hydrochloric and sulphuric, and of certain salts like zinc chloride, $ZnCl_2$, convert aldehyde at ordinary temperatures into its polymer *paraldehyde*. Commercially it is prepared by the action of hydrochloric upon aldehyde until the resulting product is no longer soluble in its own volume of water, and then purifying by redistillation and freezing and expressing. Its properties are thus described officially: "Paraldehyde is a colorless, transparent liquid, having a strong, characteristic, but not unpleasant or pungent odor, producing first a burning and then a cooling sensation in the mouth. One mil of Paraldehyde dissolves in 8 mils of water at 25° C. (77° F.); also in 17 mils of boiling water; miscible with alcohol, chloroform, ether, or volatile oils. It is neutral or only slightly acid to moistened litmus paper. Specific gravity: about 0.990 at 25° C. (77° F.). It boils between 120° and 125° C. (248° and 257° F.). Congealing point: not below 6° C. (42.8° F.). When heated with a small portion of sulphuric acid, Paraldehyde is converted into acetaldehyde, recognizable by its odor. Heat 5 mils of Paraldehyde on a water bath; no disagreeable odor is noticeable as the last portions evaporate (*impurities derived from fusel oil*) and not more than 0.0025 Gm. of residue remains. One mil of Paraldehyde forms a clear solution free from oily drops with 10 mils of distilled water (*amyl alcohol*), and 5 mil portions of this solution, tested separately, when acidulated with nitric acid, yield no turbidity on the addition of a few drops of barium chloride T.S. (*sulphuric acid*) nor an opalescence with a few drops of silver nitrate T.S. (*hydrochloric acid*). A mixture of 8 mils of Paraldehyde and 8 mils of alcohol with 1 drop of phenolphthalein T.S. acquires a pink color upon the addition of 0.5 mil of normal potassium hydroxide V.S. (*free acid*). Shake 5 mils of Paraldehyde with 5 mils of potassium hydroxide T.S.; the aqueous layer is not colored yellow or brown within one hour (*acetaldehyde*)." *U. S.*

The British Pharmacopœia gives the following properties and tests: "A clear, colorless liquid. Characteristic, ethereal odor; taste acrid, afterwards cool. Soluble in 9 parts of *water;* less soluble in hot *water*. Miscible in all proportions with *alcohol* (90 per cent.), and with *ether*. Aqueous solution neutral or only slightly acid to *litmus*. Specific gravity 0.998 to

1.000. Solidifies at a low temperature; melting point not under 10° C. (50° F.). Not more than 5 per cent. distils under 123° C. (253.4° F.), and the remainder distils between 123° and 125° C. (253.4° and 257° F.). When 5 millilitres are shaken with 5 millilitres of *solution of sodium hydroxide* and allowed to separate, the aqueous layer does not exhibit more than a faint yellow coloration within one hour (limit of acetaldehyde). An aqueous solution (1 in 10) yields no characteristic *reactions* for chlorides or for sulphates." *Br.*

Uses.—In moderate doses paraldehyde causes, both in man and the lower animals, sleep which is indistinguishable from natural sleep and is unaccompanied with any marked change in the circulation, respiration, or sensibility. After large quantities the sleep becomes of a more comatose character, there is diminution of reflex activity and considerable slowing of the respiration, the circulation, however, being scarcely affected. It is asserted by Quinquaud that after fatal doses methemoglobin appears in the blood. Death is alleged to have been produced by four ounces in man, but Probst reports a case in which five ounces were taken within a period of sixty hours, causing a profound coma, lividity, and slight fall of bodily temperature, but with no pronounced circulatory disturbances and recovery on the seventh day. It is eliminated partly through the urine and partly with the breath in each of which it may be detected by its odor.

Paraldehyde is a promptly acting somnifacient of moderate power, useful in those types of *sleeplessness* which are not dependent upon pain. Its effects are generally manifest within fifteen to thirty minutes and last two or three hours. Its chief disadvantages are its occasional tendency to cause gastric disturbance and the unpleasant odor which it imparts to the breath. It has also been recommended for the relief of *asthma.*

Dose, one-half to one and one-half fluidrachms (1.8–5.5 mils).

PELLETIERINÆ TANNAS. U. S., Br.

PELLETIERINE TANNATE Pellet. Tann.

(pĕl-lę-tĭ-ę-rĭ'næ tăn'năs)

"A mixture in varying proportions of the tannates of four alkaloids (punicine, isopunicine, methyl-punicine, and pseudo-punicine), obtained from pomegranate. Preserve it in small, well-closed containers, protected from light." *U. S.* "Pelletierine Tannate is a mixture of the tannates of the alkaloids obtained from the bark of the root and stem of Punica Granatum, *Linn.*" *Br.*

Pelletierinum Tannicum, Punicinum Tannicum; Punicine Tannate; Tannate de Pelletiérine, *Fr. Cod.*; Gerbsaures Pelletierin, Punicin, *G.*

Preparation.—The bark of *Punica Granatum* is ground, and mixed with milk of lime; the mixture is percolated with water, the percolate shaken with chloroform, and the separated chloroformic liquid which contains in solution the mixed alkaloids, is treated with a weak solution of sulphuric acid; upon the addition of a solution of tannic acid to the neutralized acid solution of the alkaloids, tannates are precipitated; these are washed and dried.

Properties.—The alkaloidal mixture known as Pelletierine Tannate is officially characterized as follows: "A light yellow, odorless, amorphous powder, having an astringent taste, and a weak acid reaction. One Gm. of Pelletierine Tannate dissolves in 240 mils of water, 16 mils of alcohol, and in 420 mils of ether at 25° C. (77° F.); dissolved by warm dilute acids; insoluble in chloroform. Ferric chloride T.S. colors aqueous solutions of the salt blue-black. No weighable ash remains on incinerating 0.2 Gm. of Pelletierine Tannate. Platinic chloride T.S. produces no precipitate in a cold solution of about 0.1 Gm. of Pelletierine Tannate in a mixture of 4 mils of distilled water and 1 mil of diluted hydrochloric acid (*foreign alkaloids*). Dissolve about 0.5 Gm. of Pelletierine Tannate, accurately weighed, in 5 mils of potassium hydroxide T.S. and shake the solution in a separator with 10 mils of chloroform and then with two or more successive portions of 5 mils each of chloroform. Acidulate the combined chloroform solutions with 0.1 mil of hydrochloric acid, evaporate it to apparent dryness, dissolve the residue in 5 mils of alcohol, again evaporate, and dry for one hour at 60° C. (140° F.). The weight of residue so obtained corresponds to not less than 20 per cent. of the weight taken. The residue obtained in the preceding test responds to the following tests for identity and purity. Stir about 0.001 Gm. of the residue on a white porcelain surface with 2 drops of sulphuric acid containing 0.005 Gm. of selenous acid in each mil. and warm the mixture; a light bluish-green color is produced which gradually changes to dark green. Stir about 0.001 Gm. of the residue on a white porcelain surface with 2 drops of sulphuric acid or nitric acid; no color other than a light yellow is produced." *U. S.*

"A light yellow, amorphous powder. Slightly soluble in *water,* more soluble in *alcohol* (90 per cent.). An aqueous solution gives with *T. Sol. of ferric chloride* a bluish-black color; with *solution of silver nitrate* a brown color rapidly deepening, with separation of metallic silver; and with *solution of auric chloride* a deep purple color, with separation of metallic gold. When heated, Pelletierine Tannate turns brown at about 150° C. (302° F.), softens at about 165° C. (329° F.); and at a higher temperature decomposes without melting. No appreciable ash." *Br.*

Uses.—Pelletierine tannate represents the tenicidal properties of Granatum, see page 533.

Dose, three to five grains (0.2–0.3 Gm.).

PEPO. U. S. (Br.)

PEPO [Pumpkin Seed]

(pē'pō)

"The dried ripe seeds of cultivated varieties of *Cucurbita Pepo* Linné (Fam. *Cucurbitaceæ*), without the presence or admixture of more than 5 per cent. of other substances." *U. S.* "Melon Pumpkin Seeds are the prepared fresh ripe seeds of cultivated plants of Cucurbita maxima, *Duch.* Melon Pumpkin Seeds must not be more than one month old, and when required for use about 100 grammes are bruised with a little water or milk to a creamy consistence and administered as a single dose." *Br.*

Cucurbitæ Semina Præparata, *Br.;* Melon Pumpkin Seeds; Semen Peponis, Semina Cucurbitæ; Semences de Potirons ou de Courge, *Fr.;* Kürbissamen, Kürbiskörner, Graumontsamen, *G.;* Calabaza (Semilla), *Sp.*

The *Cucurbita Pepo,* or *common pumpkin,* is a plant almost too well known to need description. The seeds are the part used. These are officially described as follows: "Broadly elliptical or ovate, from 15 to 23 mm. in length and from 2 to 3 mm. in thickness; externally yellowish-white, very smooth, occasionally with thin, transparent fragments of adhering pulp and with a shallow groove parallel to and within 1 mm. of the margin; fracture short, seed-coat consisting of a white coriaceous outer layer and a membranous inner layer occasionally of a dark green color; embryo whitish, straight, with a small conical hypocotyl and two plano-convex cotyledons; slightly odorous when contused; taste bland and oily. Under the microscope, sections of Pepo show an outer epidermal layer consisting of palisade-like cells, the radial walls attaining a length of 1 mm., the outer walls being usually torn off so that it appears as though the seeds were covered with very long hairs; a sub-epidermal layer consisting of from 5 to 12 rows of cells with slightly thickened, lignified and porous walls; a layer of strongly lignified stone cells, elliptical in outline and about 0.075 mm. in length; a single layer of small cells resembling those of the sub-epidermal layer; several rows of parenchyma cells with characteristic reticulate markings and separated from each other by large intercellular spaces; several layers of parenchyma cells, the inner layer being more or less collapsed and bounded on the inside by a single epidermal layer, the cells having rather thick walls; the perisperm cells are usually more or less collapsed and the endosperm consists of a single layer of cells filled with small aleurone grains; the cotyledons consist of thin-walled, isodiametric, elongated or palisade-like cells containing a fixed oil and numerous small aleurone grains." *U. S.*

The British Pharmacopœia recognizes the melon pumpkin seeds, under the title of *Cucurbitæ Semina Præparata.* These are derived from a closely related species, *Cucurbita maxima* Duch., which closely resembles *C. Pepo* and differs in that the margins of the leaves possess rounded teeth, whereas in *C. Pepo* they are acute. The British definition and description are as follows: "Flat, ovate, white, and exalbuminous, consisting of two fleshy, easily separable cotyledons, freshly deprived of the yellowish outer, and brownish inner integument. Faint odor; taste very slight. Before preparation, the seeds measure from eight to twenty millimetres in length, and from nine to twelve millimetres in breadth." *Br.*

They contain a fixed oil, consisting of the glycerides of palmitic, myristic, and oleic acids, with some free fatty acid, an aromatic principle, chlorophyll, sugar, starch, and, according to Dorner and Wolkowich, an alkaloid, *cucurbitine.* Deprived of their coating, and exhausted by ether, they yield 30 per cent. of fixed oil. (*Ann. Thér.,* 1862, p. 176.) The researches of Dorner and Wolkowich have not received confirmation, and their alkaloid probably has no existence. Pumpkin seed oil has a sp. gr. at 15° C. (59° F.) of 0.923, and solidifies at –15° C. (5° F.). The cold drawn oil is used for culinary purposes and the lower qualities for burning. The oil dries very slowly. (Lewkowitsch, *Chem. Analysis of Oils,* etc., 2d ed., 1898, 372.) Sieker obtained 30 per cent. of the oil from the seeds; it was reddish-yellow in color, soluble in ether, benzene, and carbon disulphide, but insoluble in alcohol. (*Proc. A. Ph., A.,* 1897, 545.) Willard Graham endeavored to prepare *Oil of Pumpkin Seed* by expression, but failed to obtain appreciable quantities even under a pressure of 3000 pounds. By extraction with acetone the ground seed yielded 25 per cent. of oil, clear reddish, limpid, and of agreeable odor and taste. Its sp. gr. at 15° C. (59° F.) was 0.9208; saponification number, 192.5; acid number, 18.9; ether number, 173.6; soluble in all proportions of carbon disulphide, ether, chloroform, and in twenty parts of absolute alcohol, and drying on standing to a tough, yellowish, transparent mass. These properties and constants agree well with a commercial specimen, evidently also obtained by extraction. The latter, however, had a lower acid number, 3.5, while the ether number was somewhat higher, 191.7. (*A. J. P.,* 1901, 352.) J. C. Lyons used an ounce of the oil with success in a case of tapeworm (*A. J. P.,* 1865, 253), but Wolff has found it inert when pure and free from resin, which he prepares by extracting the oil from the powdered seeds by means of petroleum benzin, then treating the remaining powder with ether, chloroform, and alcohol, which yields on evaporation a soft greenish-brown resinous liquid resembling the oleoresin of male fern. Heckel was the first to assert that the active principle is a resin, and in this he has been corroborated by L. Wolff (pamphlet, Phila., 1882), who found the resin to be efficient in doses of fifteen grains (1 Gm.), given in pill followed in two or three hours by castor oil, and who recommends an alcoholic fluidextract as the best preparation of the drug after the resin.

Power and Salway (*J. Am. C. S.*, 1910, p. 346) found the resin as well as the oil which they separated from the seed, destitute of anthelmintic powers.

W. E. Miller (*A. J. P.*, 1891, 585) analyzed both the shells and the kernels of pumpkin seed. He also found a resin soluble in alcohol, and a dark reddish fixed oil.

Uses.—It is said that in Italy the seeds of the *Cucurbita maxima,* and in the West Indies those of *C. occidentalis,* have been long used in doses of an ounce and a half as tenifuges. In the *Dictionary of Materia Medica* by Mérat and De Lens (ii, 493) it is stated that Hoarau had reported that in the Isle of France the seeds of a small variety of pumpkin were used against the *tapeworm,* and with never-failing success. In the year 1820, Mongeney, a physician of Cuba, published the results of his experience with the flesh of the pumpkin in the same disease. He had discovered the remedy by accident, and found it uniformly successful. He gave to the patient, in the morning, fasting, about three ounces of the fresh pumpkin in the form of a paste, and followed it at the end of an hour by about two ounces of honey, which latter was twice repeated at intervals of an hour. So far as we know, attention was first directed to it in this country by Richard Soule. (*B. M. S. J.*, Oct., 1851.) Since this time the drug has steadily grown in favor, and, properly used, is one of our most efficient and harmless tenifuges. The patient should be allowed only a light supper of bread and milk, in the morning early should take an ounce and a half of the seeds, a cup of tea or coffee an hour later, but no food, at 10 A.M. a brisk cathartic, and two hours later a substantial meal. We have obtained excellent results from the exhibition of the beaten seeds in the form of an electuary strongly flavored with oil of cinnamon or of gaultheria.

Dose, one to two ounces (31–62 Gm.).

PEPSINUM. U. S., Br.

PEPSIN Pepsin.

(pĕp-sĭ'nŭm)

"A mixture containing a proteolytic ferment or enzyme, obtained from the glandular layer of the fresh stomach of the hog (*Sus scrofa,* var. *domesticus* Gray) (Fam. *Suidæ*). It digests not less than 3000 times its own weight of freshly coagulated and disintegrated egg albumen. Pepsin of a higher digestive power may be brought to this standard by admixture with pepsin of a lower digestive strength or with sugar of milk. Preserve it in well-closed containers." *U. S.* "Pepsin is an enzyme obtained from the fresh and healthy stomach of the pig, sheep, or calf." *Br.*

Pepsine, *Fr. Cod;* Pepsinum, *P. G.;* Pepsin, *G.;* Pepsina, *It.;* Pepsina medicinal, *Sp.*

The U. S. P. 1890 recognized two pepsins, one under the name "Pepsinum," the other "Pepsinum Saccharatum": the first, or strong pepsin, should digest at least 3000 times its own weight of freshly coagulated albumin; the other is the first product diluted with enough sugar of milk to make it contain 10 per cent. of the strong pepsin. The U. S. P. (8th Rev.) retained the standard of strength of the previous Pharmacopœia for the strong pepsin, but modified the assay process, and dropped Saccharated Pepsin, but the latter is included in the N. F. IV. (See Part III.) The U. S. P. IX pepsin is practically the same as that of the previous edition.

It is now clearly recognized that pepsin owes its digestive action to the presence of a ferment or enzyme, and, although many researches have been made to obtain the pure principle, the nearest approaches have resulted only in producing pepsin of increased digestive power. Pepsins having much greater digestive capacity than that chosen for the U. S. official standard have been manufactured, but for all practical purposes the official pepsin is sufficiently concentrated, and indeed it is usually diluted for internal administration.

Various attempts have been made to concentrate and bring to a convenient form for administration the peptic principle of the gastric juice. It must not be supposed that the substances prepared with this object and sold under the name of pepsin have any claim to be considered as a pure definite principle. The one which for a long time was the best in the market was prepared by Boudault by a process which was afterwards essentially adopted in a former French Codex.

The U. S. Pharmacopœia recognized pepsin for the first time in the revision of 1880, but it had then been for some years largely used by the American profession. Much of the pepsin thus employed was obtained from Europe, and was of very various quality, most of it being heavily loaded with starch, and some of it containing little or no pepsin. Several American brands were early put upon the market which were superior to Boudault's pepsin. For the process for *Boudault's pepsin,* see *U. S. D.,* 17th ed., 1014. Various processes also have been recommended for obtaining pepsin. The most elaborate and valuable investigation of the subject as yet made is that of E. Scheffer (*A. J. P.,* 1872). He found that various salts, such as sodium and magnesium sulphates and sodium chloride, precipitate pepsin, and, acting upon this discovery, he devised the following processes: Mucous membrane of the pig's stomach, dissected off and finely chopped, is macerated in water acidulated with hydrochloric acid for several days, with frequent stirring. The strained liquid, if not clear, is clarified by allowing it to stand for twenty-four hours and decanting. Sodium chloride is then thoroughly mixed with it. After several hours the floating pepsin is skimmed from the surface and put on a cotton cloth to drain, and finally submitted to strong pressure

to get rid of saline solution." This pepsin, when air dried, is very tough, parchment-like or leathery, varying in color from a dim straw-yellow to a brownish-yellow. To make his *saccharated pepsin,* Scheffer added sugar of milk until a powder was obtained of which 10 grains dissolved 120 grains of coagulated albumin. After framing his original process, he increased the strength of saccharated pepsin. *Purified pepsin* he made by redissolving the pepsin in acidulated water and precipitating as before, immersing the product when perfectly dry in pure water for a short time. A half-grain of this dissolved 1500 grains of albumin.

The chemical relations of pepsin are so delicate and wide spread that it ought to be given by itself, or in combination only with an insoluble substance, or suspended in inert liquids. For an interesting paper by B. T. Fairchild on Animal Digestive Ferments, reader is referred to *A. J. P.,* Feb. and Mar., 1902.

Since Scheffer's researches were made known, pepsin has been manufactured in the United States in immense quantities, the tendency having been towards strengthening and purifying the product. For Jenkin's process for making pepsin on a large scale, see *U. S. Dispensatory,* p. 920, 19th ed. Many other substances than sugar of milk have been used to mix with pepsin, as egg and blood albumin, fibrin, and substances which are easily converted into peptones. The process for making most commercial pepsins may be briefly stated as follows. The inner membranous linings of hogs' stomachs are washed, passed through a mincing machine, and the resulting mass digested with diluted hydrochloric acid; the solution is strained or filtered and evaporated *in vacuo* or placed on shallow trays, so that a syrupy liquid which has not been subjected to a higher temperature than 44.5° C. (112° F.) is produced; this is spread upon glass plates to dry, and the scales which are formed scraped off. The thickness of the scales may be varied by using more or less concentrated solutions, and the proportion of peptone is increased by extending the length of time in the digestion process and raising the temperature to the utmost safe limit. Numerous pepsins of value are upon the market, and they are so readily tested that the practitioner need not be at a loss. (See *Proc. A. Ph. A.,* 1884, 1886, and 1890; *Ph. Rec.,* 1893, 104; *West. Drug.,* 1887, 69; *Am. Drug.,* 1885, 103.)

Properties.—Pepsin is in "lustrous, white, pale yellow or yellowish, transparent or translucent scales, grains or spongy masses, or as a fine, white or cream-colored, amorphous powder, free from any offensive odor, and having a slightly acid or saline taste. It is not more than slightly hygroscopic. One Gm. of Pepsin dissolves in about 50 parts of water, the solution being more or less opalescent; nearly insoluble in alcohol, chloroform or ether. An aqueous solution of Pepsin (1 in 50) is acid to litmus. When in solution, Pepsin is incompatible with alkalies, alkali earths, or alkali carbonates. The presence of hydrochloric acid of greater strength than 0.5 per cent. in Pepsin solutions inhibits its proteolytic activity. A precipitate is produced in its solution by the salts of many heavy metals, and by tannic acid or gallic acid. A saturated solution of Pepsin in acidulated water when heated to 100° C. (212° F.) becomes milky, or yields a light, flocculent precipitate, and loses all proteolytic power. In a dry state it is not injured if subjected to the above temperature. The activity of Pepsin in solution is destroyed by temperatures exceeding 70° C. (158° F.).

"**Assay.**—Mix 25 mils of normal hydrochloric acid V.S. with 275 mils of distilled water and dissolve 0.1 Gm. of Pepsin in 150 mils of this liquid. Immerse a hen's egg, which is not less than five nor more than twelve days old and has been kept in a cool place, in boiling water during fifteen minutes. As soon as the egg has sufficiently cooled to handle it, remove the pellicle and all of the yolk; at once rub the albumen through a clean, dry, hair or brass, No. 40 sieve, reject the first portion that passes through the sieve, and place 10 Gm. of the succeeding portion in a wide-mouthed bottle of 100 mils capacity. Immediately add 2 mils of the acid liquid and, with the aid of a rubber-tipped glass rod, moisten the albumen uniformly. Again add 2 mils of the acid liquid, repeat the manipulation with the glass rod, and with gradually increasing portions of the acid liquid, until the total amount added measures 20 mils. Thoroughly separate the particles of albumen from each other, rinse the rod with 15 mils more of the acid liquid, and, after warming the mixture to 52° C. (125.6° F.), add exactly 5 mils of the solution of Pepsin. At once cork the bottle securely, invert it three times, and place it in a water bath that has previously been regulated to maintain a temperature of 52° C. (125.6° F.). Keep it at this temperature for two and one-half hours, agitating the contents every ten minutes by inverting the bottle once. Then remove it from the water bath, pour the contents into a conical measure having a diameter not exceeding 1 cm. at the bottom, and transfer the undigested egg albumen which adheres to the sides of the bottle to the measure with the aid of small portions (about 15 mils at a time) of distilled water, until the total amount used measures 50 mils. Stir the mixture well and let it stand for half an hour; the deposit of undissolved albumen does not then measure more than 1 mil. The relative proteolytic power of Pepsin, stronger or weaker than that just described, may be determined by ascertaining through repeated trials the quantity of the Pepsin solution, made as directed in the assay, required to digest, under the prescribed conditions, 10 Gm. of boiled and disintegrated egg albumen. Divide 15,000 by this quantity expressed in mils to ascertain how many parts of egg albumen one part of Pepsin will digest." *U. S.*

"A light yellowish-brown powder, or pale

yellowish, translucent scales, having a faint odor. Tested as follows it dissolves 2500 times its weight of coagulated white of egg in six hours, the resulting solution being faintly opalescent:—Prepare some coagulated white of egg by boiling fresh eggs in water for fifteen minutes, immersing them in cold water until cool, separating the whites, at once rubbing these through a hair-sieve having 12 meshes to a centimetre, and using the product before it has lost moisture by evaporation. Prepare also a Pepsin solution by triturating 0.25 gramme of the Pepsin with 1 gramme of *sodium chloride* in a small mortar until thoroughly mixed, adding by degrees acidified water (prepared by diluting 6.5 millilitres of *hydrochloric acid* to 1000 millilitres with *water*), continuing the trituration, transferring to a litre flask, washing the mortar with acidified water, and adding the washings to the contents of the flask until 1000 millilitres are produced, then shaking frequently during six hours, and again immediately before use. Introduce 20 millilitres of the Pepsin solution so prepared into a 250 millilitre flask. Triturate 12.5 grammes of the freshly prepared coagulated white of egg in a small mortar with 50 millilitres of acidified water until reduced to uniform granules. Transfer to the flask, rinsing the mortar with a further 50 millilitres of acidified water, adding the rinsing to the contents of the flask. Immerse the flask in a water-bath so that its contents are on a lower level than the water in the bath, and digest at a temperature between 40° and 41° C. (104° and 105.8° F.) for six hours, shaking at intervals of fifteen minutes." *Br.*

In estimating the proteolytic power of pepsin by any method it is very important to adhere strictly to each requirement, otherwise great variations may be expected. (*Proc. A. Ph. A.*, 1893, 411, 722; 1894, 221; 1895, 244, 338; 1896, 260, 263; 1897, 745; *Am. Drug.*, 1894, 212; 1895, 101; *D. C.*, 1896, 52; *P. J.*, 1897, 561; *Proc. A. Ph. A.*, 1899, 307; *Ap. Ztg.*, 1900, 485, 512; *D. C.*, March, 1902.)

Three distinct types of pepsin are found in commerce: (1) Pepsins insoluble in water without the addition of traces of acids; (2) Pepsins soluble in water forming transparent solutions; (3) Pepsins not entirely soluble in water or in diluted hydrochloric acid. The objection to the insoluble pepsins is, of course, the inconvenience resulting from their insolubility in water, but, on the other hand, they are not hygroscopic, do not deteriorate so rapidly, and are active in contact with the gastric juice. The objection to the soluble pepsins is that they are hygroscopic, but they are, when good, well suited for making solutions, wines, etc. Most of the pepsin used at the present time is what is known as scale pepsin and contains from 8 to 12 per cent. of hydrochloric acid.

The inner coat of the gizzard of the South American ostrich is said, in the state of powder, to be used in Buenos Ayres as a remedy in *dyspepsia* (E. S. Wayne, *A. J. P.*, March, 1868, p. 123), and the dried crops and gizzards of chickens and turkeys have long been used in some portions of this country as a domestic remedy. For an account of *Rennet*, see Part II.

Carl T. Hackenberg (*Ph. Ztg.*, 1913, p. 592) condemns the practice of pharmacists of keeping on hand stock solutions of pepsin and alleges that in the concentration of hydrochloric acid necessary to preserve them the deterioration in proteolytic power is rapid. The peptic ferment is an extremely unstable body being destroyed by tannins, alcohol, the salts of the heavy metals and strong acids. Tocher, as the result of an experimental study, concludes that: Solutions of sodium bicarbonate, sodium, potassium, and ammonium hydrates when added to solutions of pepsin in the cold have an immediate inhibitory or destructive effect on pepsin, according to the concentration; dilute solutions of caustic alkali immediately destroy the activity of dilute solutions of pepsin; carbonate of bismuth precipitates pepsin from aqueous solutions; sub-nitrate does not; compound mixtures containing solution of bismuth, morphine, carmine, etc., should contain no pepsin, since the activity of the enzyme is much retarded by the morphine and is destroyed proportionately to the amount of alkali present in solution. (*Year Book of Pharmacy*, 1906, pp. 307–313.)

Uses.—Gastric juice was used by Dr. P. S. Physick, the celebrated physician of Philadelphia, nearly a century ago as a local application in *cancers* and *sloughing ulcers*, with a view of removing the dead flesh and correcting the offensive odor and affording a healthy stimulus to the diseased surface. The first to have suggested pepsin as a remedy in disturbances of the stomach seems to have been Corvisart. (*J. P. C.*, xxx, p. 169.) It is now very largely used with the idea of improving the digestive powers of the stomach by supplying the essential ferment. Its value in *dyspepsia*, however, is greatly over-estimated. *Pepsinogen*—from which the active peptic enzyme is derived by the action of the hydrochloric acid—is rarely lacking save in cases of cancer and other very severe diseases of the stomach. When gastric digestion fails it is generally because of the absence of hydrochloric acid in sufficient quantity to activate the pepsinogen. Therefore in our opinion pepsin is not indicated in the ordinary types of *indigestion* or *gastritis*. It appears, however, to have some sedative influence upon the mucous membrane of the stomach, not due to its digestive powers, and is often of service for the relief of certain forms of *nausea* and to lessen the ill effects of such drugs as the iodides and salicylates upon the stomach. Locally it is still used occasionally for the purpose of dissolving the false membrane in *diphtheria* and hastening the sloughing off of dead tissue in *foul ulcers*.

It would seem trite to say that when pepsin

is used as a digestive ferment it must be given in an active form and in sufficient dose to have some influence, were it not for the fact that this truism is so often forgotten. The enzymic activity of pepsin is so easily destroyed by heat and chemical agents, that it should be administered always either alone as a powder or in solution with minute quantities of hydrochloric acid only. The dose of four or five grains of pepsin so often recommended is quite inadequate to seriously influence gastric digestion; if the physician is employing the pepsin with any idea of hastening digestion he should give at least from fifteen to thirty grains (1–2 Gm.) at a dose.

Pepsin should preferably be administered in its original form. It is well to combine it with hydrochloric acid, and the powder is often advantageously exhibited in *infantile diarrhea* along with bismuth subnitrate. With these exceptions, it is usually preferable to give it by itself.

Dose, of official pepsin, may be set down as from ten to sixty grains (0.65–3.9 Gm.).

PETROLATUM. U. S. (Br.)

PETROLATUM Petrolat. [Petroleum Ointment, Petroleum Jelly, Petrolatum Molle, Petrolatum Spissum, U. S., 1890]

(pĕt-rō-lā′tŭm)

"A purified mixture of semi-solid hydrocarbons, obtained from petroleum." *U. S.* "Soft Paraffin is a mixture of semi-solid hydrocarbons." *Br.*

Paraffinum Molle, Soft Paraffin, *Br.;* Adeps Petrolei, Unguentum Paraffinum; Soft Petrolatum, Cosmoline, Vaseline, Paraffin Jelly, Soft Petroleum Ointment, Hard Petroleum Ointment, Hard Petrolatum; Pétroléine, *Fr. Cod.;* Graisse minérale, Pétréoline, *Fr.;* Weiches Paraffin, Paraffinsalbe, *G.;* Vaselina, *It., Sp.*

Petrolatum in its various forms has of late years acquired considerable importance, under various trade names, as a bland neutral body well fitted to take the place of animal and vegetable fats as a base for ointments and for other purposes. It is prepared from the residue left in the stills after a distillation of petroleum *in vacuo,* or from the residue or sediment deposited in tanks containing crude petroleum, of which large quantities collect in the storage tanks in the oil districts of Western Pennsylvania. The substances known commercially as *cosmoline* (*Unguentum Petrolei*) and *vaseline* are now made on a large scale from residues, but more largely from what are termed "reduced oils," that is, crude oils from which the lighter fractions (those included under the heads of petroleum benzin, naphtha, illuminating and paraffin oils) have been removed by distillation. This process of reducing would leave an increasing amount of black pyrogenous products in the residue, were it not that the reducing is carried out under diminished pressure, by what is termed the "vacuum process," in which, moreover, the heat is not applied directly to the still bottoms, but by means of coils of pipe, through which superheated steam is made to pass. These reduced oils can be brought to 337.7° C. (640° F.) fire-test without acquiring the slightest pyrogenous odor. They are then filtered through well-dried bone black, in chambers kept at a temperature of from 43.3° to 54.4° C. (110°–130° F.), or in some cases higher. The first portions of the filtrate are colorless, and then pass from a light straw or amber color to a color red by transmitted light and light green by reflected light. The latter product is known as "cylinder stock," and is highly prized as a lubricating oil. The clearer portion of the filtrate is then brought to the proper melting point, if necessary, by the addition of pure block paraffin, which dissolves perfectly in the warm liquid oil. The crude oil tank residues are purified in a similar manner. The "B. S. Oil," or "rod wax," as it is technically termed, is placed in a still, heat applied, and after the lighter products have distilled over, and indications of congelation are noticed when a portion of the distillate is allowed to cool, the heat is withdrawn, and the contents of the still, after having cooled, are transferred gradually to a percolator which contains recently heated animal charcoal. In place of bone black, clay has in recent years been quite largely used for clarifying purposes, the same being revivified by heat. A somewhat different process is used in Germany; the crude product is derived from crude *ozokerite,* obtained from Alsace and Galicia, or American residue is sometimes used. (1) The oil is heated by steam to about 30° C. (86° F.), mixed, at this temperature, with 10 per cent. of its weight of sulphuric acid of 60° B., stirred for half an hour, and then allowed to stand at rest, so that the carbonized portions may separate. (2) When clear, the oil is washed with an aqueous solution of potassium dichromate, whereby any remaining excess of sulphuric acid is at the same time removed. (3) The residue from the acid treatment is mixed with lime, neutralized, and disposed of to fertilizer factories. (4) The clear oil from the second step of the process, after being washed, is heated by steam to 80° C. (176° F.), mixed with 10 per cent. of its weight of granular animal charcoal, and then allowed to stand at rest, to permit the animal charcoal to settle. (5) After the latter is separated, the liquid portion is filtered through filters heated by steam. (6) The residuary magma of animal charcoal is subjected to hydraulic pressure, the expressed

oil filtered, and the solid residue again used in the next operation, a sufficient quantity of fresh animal charcoal being added to make up for any loss or waste.

The commercial varieties of petrolatum may be classed under two heads: (1) Those which, like the American vaseline, are obtained as a ready formed mixture of hydrocarbons of gelatinous consistence; (2) those made by directly mixing solid paraffin of low melting point with heavy lubricating oil, such as are known in Germany as "artificial vaseline." The latter varieties are less homogeneous, and are liable to deposit granules of paraffin on keeping, and hence are not so suited for the preparation of ointments as true American petrolatum.

In warm ether, American petrolatum dissolves freely to a clear solution exhibiting a strong blue fluorescence, and the liquid remains clear, or at most becomes only slightly turbid, on cooling. German petrolatum, on the contrary, is said to form a thick solution with warm ether, and to give a considerable deposit on cooling. Russian petrolatum is stated to dissolve completely in warm ether and give a clear solution which becomes turbid on cooling. (Allen, *Com. Org. Anal.*, 2d ed., 1887, ii, p. 408.) In the U. S. P. (8th Rev.) there are three forms of petrolatum as follows: Petrolatum, Petrolatum Album, and Petrolatum Liquidum. In the British Pharmacopœia there are three as follows: Paraffinum Liquidum, Paraffinum Molle, and Unguentum Paraffini. The Petrolatum of the U. S. P. (8th Rev.) corresponds with the Petrolatum Spissum of the U. S. Pharm. 1890. The Paraffinum Molle of the British Pharmacopœia resembles the Petrolatum Molle of the U. S. P. 1890, but is somewhat softer in consistence.

Chemical Constitution.—Petrolatum, as made from American petroleum, consists mainly of the higher members of the paraffin series, but undoubtedly contains also the higher olefines. These may possibly alter in time, and give rise to rancidity, although this is not certainly established. The paraffins, which make up the bulk of it, are not capable of direct oxidation, and are therefore not affected by atmospheric influences. Petrolatum contains hydrocarbons of the paraffin series, like $C_{16}H_{34}$, $C_{17}H_{36}$, $C_{18}H_{38}$, etc., up probably to $C_{32}H_{66}$, together with hydrocarbons of the olefine series, $C_{16}H_{32}$, $C_{17}H_{34}$, etc. These latter are less concrete than the corresponding paraffin hydrocarbons, and give petrolatum its oleaginous characters. Puckner (*A. J. P.*, July, 1914) states that American petrolatum is made up of hydrocarbons of the methane series while the Russian oil contains naphthenes.

Properties.—The U. S. Pharmacopœia describes petrolatum as follows: "An unctuous mass, varying in color from yellowish to light amber, having not more than a slight fluorescence, even after being melted; it is transparent in thin layers; completely amorphous; free or nearly free from odor or taste. Petrolatum is insoluble in water; almost insoluble in cold or hot alcohol, or in cold dehydrated alcohol; freely soluble in ether, chloroform, carbon disulphide, oil of turpentine, petroleum benzin, benzene, or in most fixed or volatile oils. Specific gravity: 0.820 to 0.865 at 60° C. (140° F.). It melts between 38° and 54° C. (100.4° and 129.2° F.). Heat about 2 Gm. of Petrolatum in an open porcelain or platinum dish, over a Bunsen flame; it volatilizes without emitting an acrid odor, and on incineration not more than 0.05 per cent. of ash remains. Shake melted Petrolatum with an equal volume of hot distilled water; the latter remains neutral to litmus (*acids or alkalies*). Digest 10 Gm. of Petrolatum at 100° C. (212° F.) for half an hour with 10 Gm. of sodium hydroxide and 50 mils of distilled water, then separate the aqueous layer and supersaturate it with sulphuric acid; no oily or solid substance separates (*fixed oils, fats,* or *rosin*)." *U. S.*

"White or yellow, translucent, soft, unctuous to the touch, not allowing any liquid to separate on keeping. No odor. Melting point 42° to 46° C. (107.6°–114.8° F.). On heating to 80° C. (176° F.) no unpleasant odor is evolved. 10 millilitres of *alcohol* (90 per cent.) boiled with 5 grammes of Soft Paraffin are not acid to *litmus*. When 10 grammes are boiled with 20 millilitres of *solution of sodium hydroxide* for ten minutes and allowed to separate, the aqueous layer yields no precipitate or oily matter when acidified with *sulphuric acid* (absence of fixed oils, fats, and resin). 5 grammes when heated burn with a luminous flame, leaving no appreciable ash." *Br.*

As it is found in the market, petrolatum varies in color, odor, and melting point. The statement frequently made by the manufacturers that it is unalterable in the air is incorrect, as we have frequently noticed that exposure to light and air causes it to assume a disagreeable odor resembling that of crude petroleum. It has been observed to have at times irritating properties. These may be due to imperfect removal of the sulphuric acid or similar agents used, but are more probably caused by rancidity or decomposition. The test of the U. S. P., 1890, which directed that only a brown color should result when sulphuric acid be added to melted petrolatum was dropped in the U. S. P. IX because it was found that a black color always results, with petrolatum now produced.

Uses.—Petrolatum is used almost exclusively as a bland, neutral, protective dressing and as a substitute for the true fats in ointments. For local applications it has the advantage over the fats that it does not become rancid. It is not suited, however, for the preparation of ointments when absorption is desired, for it is not capable of penetrating the skin. Although it was at one time suggested as a substitute for butter and animal fats for culinary purposes it has absolutely no food value. Randolph (*T. G.*, 1885, ix, p. 732) appears to have been the

first to demonstrate its non-absorbability from the intestinal tract, and Robinson (*M. News*, 1900, lxxvii, p. 56) recovered the entire amount of liquid petrolatum from the feces which was administered by mouth. Randolph also showed that when taken internally, in doses of from one to four drachms (3.9–15.5 Gm.), it acts as a feeble laxative and soothes irritation, so as to be advantageous in inflammations of the gastro-intestinal mucous membrane. (See *Petrolatum Liquidum.*)

Off. Prep.—Unguentum Paraffini, *Br.;* Emulsum Petrolati, *N. F.*

PETROLATUM ALBUM. U. S.

WHITE PETROLATUM Petrolat. Alb. [White Petroleum Jelly]

(pĕt-rŏ-lā'tŭm ăl'bŭm)

"Petrolatum wholly or nearly decolorized." *U. S.*

Preparation.—*White petrolatum* was introduced for the first time into the U. S. P. (8th Rev.) under its present official title; there are reasons for believing that much that is in the market is not the natural product deprived of its color by treatment with animal charcoal, but an artificial compound made by melting together paraffin wax and liquid petrolatum, and stirring until cold. This manufactured product is opalescent and usually granular in appearance and is excluded by the official description.

This artificial product, under the name of *Snow white mineral jelly,* is extensively used in preparing petrolatum cold creams, but usually separates some of the liquid portion when the attempt is made to incorporate other ingredients by rubbing.

Properties.—It is officially described as "White Petrolatum is a white or faintly yellowish unctuous mass, transparent in thin layers even after cooling to 0° C. (32° F.); completely amorphous. In other respects White Petrolatum has the characteristics of and responds to the tests for identity and purity under *Petrolatum.*" *U. S.*

Uses.—See *Petrolatum.*

PETROLATUM LIQUIDUM. U. S. (Br.)

LIQUID PETROLATUM Petrolat. Liq. [Mineral Oil]

(pĕt-rŏ-lā'tŭm lĭq'ŭ-dŭm)

"A mixture of liquid hydrocarbons obtained from petroleum. Preserve it in well-closed containers, protected from light." *U. S.* "Liquid Paraffin is a mixture of liquid hydrocarbons." *Br.*

Paraffinum Liquidum, *Br.,* Liquid Paraffin; Paraffine liquide, Huile de Paraffine, *Fr.;* Flüssiges Paraffin, Paraffinöl, *G.;* Aceite de paraffina, *Sp.*

Preparation.—*Liquid petrolatum* is made by distilling the residuary liquid boiling between 330° and 390° C. (626° and 734° F.), obtained after removing the lighter hydrocarbons from petroleum. It is purified and decolorized by first treating it with sulphuric acid and then with caustic soda and passing it while hot, through animal charcoal. By cooling, some solid paraffins will separate; the liquid is then redistilled, and the portion boiling below 360° C. (680° F.), rejected. It has been sold under various proprietary names as *albolene, glycoline,* etc., and since its introduction into the U. S. P., 1890, has been largely used in medicine and for pharmaceutical purposes.

Properties.—It is described officially as follows:

"**Heavy Liquid Petrolatum.**—Heavy Liquid Petrolatum has a viscosity of *not less* than 3.1 when determined by the test given below.

"**Light Liquid Petrolatum.**—Light Liquid Petrolatum has a viscosity of *not more* than 3 when determined by the test given below and vaporizes freely. *Each variety conforms to the following description and tests:* Specific gravity for Liquid Petrolatum 0.828 to 0.905 at 25° C. (77° F.). A colorless, transparent, oily liquid, free, or nearly free, from fluorescence, odorless and tasteless when cold, and possessing not more than a faint petroleum odor when heated. When cooled to 10° C. (50° F.), Liquid Petrolatum does not become more than opalescent (*solid paraffins*). Insoluble in water or alcohol; soluble in ether, chloroform, petroleum benzin, or in fixed or volatile oils. Camphor, menthol, thymol, and many similar substances are dissolved by Liquid Petrolatum. Boil 10 mils of Liquid Petrolatum with an equal volume of alcohol; the alcoholic liquid is not acid to litmus (*acids*). Introduce into a glass-stoppered cylinder, which has been previously rinsed with sulphuric acid, 5 mils of Liquid Petrolatum and 5 mils of colorless sulphuric acid, heat in a water bath during ten minutes, shaking well at intervals of thirty seconds; the oil remains unchanged in color and the acid does not become darker than pale amber (*carbonizable impurities*). Prepare a clear, colorless saturated solution of lead oxide in an aqueous solution of sodium hydroxide (1 in 5), and mix 2 drops of this solution with 4 mils of Liquid Petrolatum and 2 mils of dehydrated alcohol; the mixture does not darken after heating for ten minutes at 70° C. (158° F.) and cooling (*sulphur compounds*).

"**Viscosity.**—Make a permanent mark about 2 cm. below the bulb of a 50 mil pipette of the usual type and note the time, in seconds, required at 25° C. (77° F.) for the level of distilled water to fall from the upper to the lower mark as the liquid flows from the pipette. The time should not be less than twenty-five seconds nor more than thirty seconds for the pipette selected. Draw the Liquid Petrolatum to be tested into this pipette, which should be clean and dry, and note the time, in seconds, required at 25° C. (77° F.) for its level to fall from the same upper to the lower mark as used for the water. Divide the number of seconds thus noted by the number of seconds required for water to fall from the upper to the lower mark, as above determined. The quotient indi-

cates the viscosity. Distilled water at 25° C. (77° F.) is taken as 1." *U. S.*

In the U. S. P. IX two kinds of Liquid Petrolatum were introduced, one being called "heavy," the other "light." The proportion of viscosity is the determining factor, "heavy" requiring not less than 3.1, "light" not more than 3, as determined by the official test. For atomizing purposes light liquid Petrolatum is used and for constipation treatment heavy liquid petrolatum is preferred.

The British Pharmacopœia describes it as "transparent, colorless, not fluorescent. No odor or taste. Specific gravity 0.860 to 0.890. A mixture of 4 millilitres of Liquid Paraffin, 2 millilitres of *absolute alcohol,* and 2 drops of a clear saturated solution of *lead oxide* in *solution of sodium hydroxide,* remains colorless when kept at 70° C. (158° F.) for ten minutes (absence of sulphur compounds). When 3 millilitres are heated with an equal volume of *sulphuric acid* in a test-tube placed in boiling *water* for ten minutes, and frequently shaken, the acid layer, after separation, is not darker than pale-brown. 10 millilitres of *alcohol* (90 per cent.) boiled with 5 millilitres of Liquid Paraffin are not acid to *litmus*." *Br.*

Uses.—Liquid petrolatum is used chiefly for its demulcent effect upon the mucous membrane of the upper respiratory tract in acute *coryza, pharyngitis,* and *laryngitis.* It is usually applied by atomization but is sometimes dropped directly into the nostril. It has also been recommended as a dressing for *wounds* and *ulcers.* Chrysopathes (*Cb. Chir.,* 1913, p. 1739) believes that it has an antiseptic effect, but it is more probable that its beneficial action is due to the exclusion of air. Although vaseline as recommended many years ago by Randolph for its laxative effect, it was not used to any large extent until in 1913 Lane (*B. M. J.,* 1913, ii, p. 1126) introduced the use of the heavy Russian liquid petrolatum in the treatment of *chronic constipation.* Since this time it has become a favorite remedy for this purpose. Its action is purely mechanical rendering the feces soft and perhaps lubricating the bowel. There is a wide spread belief among the medical profession that where used as a laxative the more viscid petrolatums are preferable. In a comparative study, however, of both the Russian and American oils ranging in specific gravity from 0.857 to 0.885, carried out by eight of the most prominent clinicians in the United States under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association (*J. A. M. A.,* 1915, lxiv, p. 808), the conclusion was reached that as far as the therapeutic results, either as regards the quantity required or the liability to leakage around the anus or other disagreeable effects, there is no difference in the effects of the heavy or light oils. The ordinary quantity required varied from one-half to three ounces, and the effects were the same whether taken in one or three doses.

The number of fancy names which have been applied to proprietary brands of liquid petrolatum has become a crying evil. The following are some of the common names and special brands of liquid petrolatum:

Adepsine oil	Nujol
American oil	Olo
Amilee	Paraffin oil
Atoleine	Paroline
Atolin	Petralol
Bakurol	Petro
Blandine	Petrolax
Crysmalin	Petrolia
Deeline	Petronol
Glyco	Petrosio
Glycoline	Rock oil
Glymol	Russian liquid petrolatum
Heavy petroleum oil	Russian mineral oil
Interol	Russian paraffin oil
Lilyolene	Russol
Liquid albolene	Seneprolin
Liquid cosmoline	Saxol
Liquid fossiline	Stanolax
Liquid geoline	Stanolind
Liquid paraffin	Terraline
Liquid petrolatum	Terralbolia
Liquid saxoline	Usoline
Liquid vaseline	Water-white mineral oil
Mineral glycerin	White liquid vaseline
Mineral oil	White paraffin oil
Minol	Whiteruss.
Muthol	
Neutralol	

A formula for an emulsion of liquid petrolatum was contributed by Miles Shimer (*Proc. P. Ph. A.,* 1916, p. 298), as follows: Soft petrolatum, 40 Gm.; white mineral oil, 200 Gm.; powdered acacia, 60 Gm.; syrup, 50 mils; rum (Jamaica), 50 mils; water, q. s. ad., 500 mils.

PETROSELINUM. U. S.

PARSLEY FRUIT Petrosel. [Parsley Seed]

(pē-trō-sę-lī'nŭm)

"The dried ripe fruit of *Petroselinum sativum* Hoffman (Fam. *Umbelliferæ*), without the presence or admixture of more than 5 per cent. of foreign seeds or other matter. Preserve Parsley Fruit carefully in tightly-closed containers, protected from light." *U. S.*

Ache, Persil, *Fr.;* Petersilie, *G.;* Prezzemolo, *It.*

Petroselinum sativum Hoffman (*Apium petroselinum* L.).—The *common parsley,* which is used extensively as a culinary herb, is a hardy biennial bearing pinnately-compound leaves, which in the cultivated varieties are greatly divided. During its early stages the leaves are arranged in rosettes and the plant is six inches or less above the ground; the flowering and fruiting plant, however, is from 2 to 3 feet in height. It is a native of Sardinia and was introduced into England in 1548, and is

naturalized in salt marshes on the coast of California. It has been cultivated as a sweet herb since earliest times and was used by the ancient Greeks and Romans as a part of their festive garlands on account of retaining its color so long.

Parsley-root is recognized by the N. F. (see Part II); it is spindle-shaped, about 1 cm. in thickness, externally white and marked with close annular wrinkles, internally fleshy and white with a yellowish central portion. It has a pleasant odor and sweetish slightly aromatic taste, but loses this property by long boiling and by time. It was formerly used as a diuretic in dropsical affections, but has been shown by Cow (*A. E. P. P.*, 1912, lxx, p. 393) to possess very feeble powers.

The fruit, which has been admitted into the U. S. P. IX consists of two dry, seed-like, mericarps, which are in the fresh state joined along the central commissure. It is officially described as follows: "Mericarps usually separated, ovoid-crescent shaped, from 2 to 3 mm. in length and about 1 mm. in diameter; externally grayish-brown, becoming grayish or brownish on aging, having 5 yellowish, filiform, prominent ribs, alternating with the coarsely roughened furrows; in transverse section nearly hemispherical, the commissural surface with 2 vittæ or oil-tubes, the dorsal surface usually with a single vitta, occasionally 2 vittæ in the groves between the primary ribs; endosperm large, oily, enclosing a small embryo; odor and taste characteristic and aromatic, especially when bruised. Under the microscope, sections of Parsley Fruit show an epidermal layer with thick cuticularized walls having numerous small centrifugal projections; several layers of small, thin-walled parenchyma cells, being usually considerably collapsed and occasionally containing a rosette aggregate of calcium oxalate; a single, large, brown, elliptical vitta or oil-tube between each of the primary ribs and surrounded by a layer of comparatively large yellowish-brown, tangentially elongated cells; a single fibrovascular bundle more or less surrounded by a few or occasionally numerous sclerenchymatous fibers; inner epidermis of narrow, thin-walled elongated cells closely cohering with the brownish tabular cells of the seed-coat; commissural surface usually with 2 large vittæ, a very few stone cells and showing a slight separation of pericarp and seed-coat; endosperm of polygonal, thick-walled parenchyma cells containing fixed oil and numerous, small aleurone grains usually containing a small rosette aggregate of calcium oxalate. The vittæ usually contain yellowish oil globules or a resin-like mass adhering to the walls, and occasionally are divided by a radial wall. The powder is grayish-brown; mostly of large, irregular fragments; cells of endosperm with aleurone grains, each usually containing a rosette aggregate of calcium oxalate, from 0.003 to 0.007 mm. in diameter; fragments with light yellow vittæ and the yellowish-brown cells of the pericarp: fragments with narrow tracheæ and more or less lignified sclerenchymatous fibers." *U. S.*

All parts of the plant contain a volatile oil, to which it owes its odor and mainly its taste, as well as its use in seasoning. This oil consists of a hydrocarbon, $C_{10}H_{16}$, probably pinene, and apiol. Braconnot obtained from the herb a peculiar substance, resembling pectic acid in appearance, which he named *apiin*. It is procured by boiling the herb in water, straining the liquor, and allowing it to cool. The apiin then forms a gelatinous mass, which requires only to be washed with cold water. (*Ber. d. Chem. Ges.*, 1876, 1121) found that by repeated dissolving of this gelatinous mass in alcohol and precipitation by water it could be purified and then obtained from concentrated alcoholic solution in silky needles of the formula $C_{27}H_{32}O_{16}$. Joret and Homolle found the seeds to contain a volatile oil, a crystallizable fatty matter, pectin, what they believe to be the apiin of Braconnot, chlorophyll, tannin, a coloring matter, extractive, lignin, various salts, and, in addition to these, a peculiar substance to which they gave the name of *apiol*. This, however, is a mixture only partly consisting of true apiol which is the di-methoxymethylene ether of allyl-tetraoxybenzene, $C_{12}H_{14}O_4$. (See *Oleoresina Petroselini.*)

Off. Prep.—Oleoresina Petroselini, *U. S.*

PHENOL. U. S. (Br.)

PHENOL [Carbolic Acid, Acidum Carbolicum, Pharm. 1890]

(phē′nŏl)

"Hydroxybenzene obtained from coal-tar or made synthetically. It contains not less than 97 per cent. of C_6H_5OH (94.05). Preserve it in well-closed containers, protected from light." *U. S.* "Phenol, C_6H_6O, commonly termed carbolic acid, may be obtained from coal-tar oil." *Br.*

Acidum Carbolicum, *Br.*, also *U. S.* 1890; Acidum Phenicum s. Phenylicum Crystallisatum; Phenic Acid, Phenylic Acid, Phenylic Alcohol, Phenic Alcohol, Benzophenol; Phénol, Acide carbolique, Acide Phénique, *Fr. Cod.*; Hydrate de Phényle, *Fr.*; Acidum carbolicum, *P. G.*; Karbolsaure, Phenylsaure, Phenylalkohol, *G.*; Fenolo cristallizzato, Acido carbolico, *It.*; Acido fenico, *Sp.*

This important medicine was discovered in 1834, in the tar of coal, by Runge, who gave it the name of carbolic acid. When on the subject of its composition, we shall have occasion to show that, although more closely related chemically with the alcohols than the acids, it belongs to a peculiar class known in common as *phenols*. The U. S. P. (8th Rev.) dropped the names of Acidum Carbolicum and carbolic acid and adopted the correct title of Phenol for this substance. The British Pharmacopœia recognizes the name Acidum Carbolicum, but uses "phenol" as the English name for this substance.

Preparation.—For the commercial preparation of phenol the light oil fraction is collected until a sample of the oil that runs from the still

sinks in water. This fraction, with a sp. gr. of from 0.94 to 0.99, boils between 90° and 250° C. (194° and 482° F.) and contains from 4 to 10 per cent. of acids, and therefore nearly all the true phenol which boils at 182° C. (359.6° F.). The oil from which the phenol is to be extracted is agitated with a weak solution of sodium hydroxide, 10 per cent. strength being strong enough. If a stronger solution is used many impurities, like naphthalene, are dissolved and contaminate the finished product. After agitation, the mixture, on standing, separates into two layers, the upper consisting of the extracted oil and the lower the solution of sodium phenolate. To this solution, after separation from the oily layer, an amount of hydrochloric or diluted sulphuric acid calculated from a special test with a small portion, as just sufficient, is then added in order to set the phenol free. It separates as an oily layer upon the surface, and, after being washed with a saturated solution of sodium chloride, is dried over calcium chloride and again distilled. The product thus obtained crystallizes out largely on a cooled surface, and, after removing the crystals from adhering liquid, and drying them by pressure, they are again submitted to the same process of distillation. Only by such a detailed procedure can phenol be separated from its homologues, like cresol (cresylic acid), $C_6H_4(CH_3)OH$, which accompany it, smell much like it, and boil between 185° C. (365° F.) and 200° C. (392° F.).

Church (*Chem. News*, Oct. 13, 1871) proposed to prepare *pure* phenol by agitating the best commercial product with 20 parts of water, siphoning off the clear solution from the undissolved portion which retains the impurities, and adding to the solution pure sodium chloride to saturation, when the purified phenol rises to the top, and may afterwards be dehydrated by distillation with lime.

Within recent years manufacturers have put upon the market "*synthetical phenol*," for which is claimed a greater purity than that extracted from coal tar. It may be made synthetically in one of two ways—either from benzene, which is converted into *benzene-sulphonic acid*, the sodium salt of which is then fused with an excess of sodium hydroxide, producing sodium phenolate and sodium sulphite, from which, on the addition of sulphuric or hydrochloric acid, the phenol separates and may be distilled off; or a pure aniline oil is taken, neutralized with sulphuric acid, and to the acid solution sodium nitrite is added. The nitrous acid liberated forms at first *diazobenzene sulphate*, but this at once decomposes into phenol, sulphuric acid, and nitrogen, the reactions being as follows:

$$(C_6H_5NH_2)_2H_2SO_4 + 2HNO_2 = (C_6H_5N=N)_2SO_4 + 4H_2O$$

$$(C_6H_5N=N)_2SO_4 + 2H_2O = 2C_6H_5OH + H_2SO_4 + 4N$$

The synthetic phenol melts at 41° to 42° C. 105.8°–107.6° F.), and boils at 178° C. (352.4° F.). The practicability of manufacture of synthetic phenol by the above process was made possible by the great increase in price soon after the beginning of the European war. It is made in America by a number of manufacturing firms.

Commercial Forms.—In one of his publications in reference to phenol, F. Grace Calvert, to whom probably more than to any other person is due the introduction of this substance into use in Great Britain and the United States, informed us that the phenol obtained by Laurent, melting at 34° C. (93° F.), and boiling at 186° C. (367° F.), was not quite pure. By successive steps of improvement in the process employed by the manufacturing house of Manchester with which he was connected, they had at length succeeded in preparing the pure crystallized acid, without color or sulphurous odor.

Impure liquors were formerly sold sometimes under the improper name of *coal tar creosote*. They were recognized in the U. S. Pharmacopœia, 1890 (*Acidum Carbolicum Crudum*), which was officially described as "a nearly colorless, or reddish, or brownish-red liquid, of a strongly empyreumatic and creosote-like odor; having a benumbing, blanching, and caustic effect upon the skin or mucous membrane; and gradually turning darker on exposure to air and light. The aqueous solution of Crude Carbolic Acid has a slightly acid reaction on litmus paper. In an aqueous solution of the Acid, bromine water produces a white precipitate. Crude Carbolic Acid should not be soluble in less than 15 parts of water at 15° C. (59° F.), and the aqueous solution should not have an alkaline reaction (absence of *alkalies*). If 50 volumes of the Acid be thoroughly agitated with 950 volumes of water, in a capacious vessel, on allowing the mixture to separate, the undissolved portion should not exceed 5 volumes, or 10 per cent. by volume of the acid (limit of other *less soluble constituents of coal-tar*)." *U. S.*, 1890. It is superior in germicidal power to pure phenol. (See *Cresol.*)

Properties.—Phenol, in its pure state, is a solid at ordinary temperatures, crystallizing in minute plates or long rhomboidal needles, white or colorless, of a peculiar odor recalling that of creosote, and an acrid burning taste. Its sp. gr. is 1.065. (Lemaire.) It is likely to become colored pinkish or brown under the influence of light and air. This reddening has been ascribed to various causes, such as ammonia and ammonium nitrite in the air, rust spots in tinned iron vessels, alkali in glass vessels, organic matter, etc. It is said to be due to oxidation; stannous chloride solution acquires a green color when shaken with the red colored phenol. Demant recommends the removal of the red color by adding to 89 parts of the melted substance 11 parts of alcohol, subjecting the mixture to freezing, and then draining off the portion remaining liquid. Perfectly white crystals can be thus obtained. A slight discoloration does not

interfere with any of the medicinal uses of phenol. Phenol deliquesces on exposure, and becomes liquid, and the presence of water in the smallest proportion causes it to liquefy. It is customary to add 10 per cent. of water or glycerin to phenol for dispensing, as it is more convenient to use in a liquid form. Such a form is now official (see *Phenol Liquefactum*). Its solution in glycerin is very useful, as the glycerite mixes with water very readily. (See *Glyceritum Phenolis.*) When diluted it has a sweetish taste with a slightly nauseating after-taste, and a faintly acid reaction. When quite pure it melts at 41° C. (106° F.), forming an oily looking, colorless liquid, and boils at 182° C. (359.6° F.) (Calvert); but, as often met with, its point of fusion is lower, and that of volatilization higher, than those named. The official tests and requirements are as follows: "Colorless, interlaced, or separate needle-shaped crystals, or as a white, crystalline mass, sometimes acquiring a red tint; having a characteristic, somewhat aromatic odor. When undiluted it cauterizes and whitens the skin and mucous membrane. One Gm. of Phenol dissolves in about 15 mils of water at 25° C. (77° F.); very soluble in alcohol, glycerin, chloroform, ether, carbon disulphide, or in fixed or volatile oils. An aqueous solution of Phenol (1 in 15) is clear and neutral or at most only faintly acid to litmus. When gently heated Phenol melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 per cent. of water. Congealing point: not below 38° C. (100.4° F.). Its aqueous solution yields with bromine water a white precipitate of tribromphenol, which at first redissolves, but becomes permanent as more of the reagent is added, and appears crystalline when viewed under the microscope. Add 1 drop of ferric chloride T.S. to 10 mils of an aqueous solution of Phenol (1 in 100); the liquid acquires a violet-red color. Heat about 10 Gm. of Phenol on a water bath; it is volatilized without leaving more than 0.05 per cent of residue. The vapor is inflammable." *U. S.*

"Small, colorless, deliquescent crystals; odor peculiar but not fetid or tarry; taste sweetish, pungent. Has a caustic action on skin and mucous membrane. Freely soluble in *alcohol* (90 per cent.), in *ether, chloroform, glycerin,* in the fixed and volatile oils, and in solutions of alkalies. Exposed to moist air it may acquire a pinkish tinge. At 15.5° C. (60° F.), 100 parts of Phenol are liquefied by the addition of 10 parts of *water,* form a clear liquid with 30 to 40 parts of *water,* and are completely dissolved by 1200 parts of *water.* The aqueous solution is clear and colorless. Melting point from 39° to 40° C. (102.2°–104° F.); boiling point not higher than 183° C. (361.4° F.). Specific gravity at the melting point 1.060 to 1.066. Phenol does not immediately redden *blue litmus paper.* Optically inactive. Coagulates *collodion* and *solution of albumen.* An aqueous solution of Phenol becomes deep purple with *T. Sol. of ferric chloride;* yields a white precipitate with excess of *solution of bromine;* and when mixed with one-fourth of its volume of *solution of ammonia,* and then with a few drops of *solution of chlorinated soda,* becomes blue after a time, or immediately on gently heating. One volume of Phenol liquefied by the addition of 10 per cent. of *water,* forms with 1 volume of *glycerin* a clear liquid which is not rendered turbid by the addition of 3 volumes of *water* (absence of cresol). Evaporated on a water-bath it leaves not more than 0.1 per cent. of residue." *Br.*

Its solubility in water increases on heating the water; at 84° C. (183.2° F.) both liquids are miscible in all proportions. Its solution is, if pure, colorless, and remains so, but, if impure, is colored brownish by exposure. It is but slightly soluble in cold petroleum benzin, but dissolves largely on heating. *Sodium sulphoricinate* has been used to increase the solubility of phenol, the advantage being that it will retain 40 per cent. of phenol in solution without destroying its antiseptic power, making a solution without causticity.

"**Assay.**—Dissolve about 1.5 Gm. of the Phenol to be assayed, accurately weighed, in sufficient distilled water to make 1000 mils. Transfer an aliquot portion of this solution, containing not less than 0.038 Gm. nor more than 0.041 Gm. of Phenol, to a 500 mil glass-stoppered flask having a long, narrow neck, add 30 mils of tenth-normal bromine V.S., then 5 mils of hydrochloric acid and immediately insert the stopper. Shake the flask repeatedly during half an hour, allow it to stand for fifteen minutes, remove the stopper just sufficiently to introduce quickly 5 mils of an aqueous solution of potassium iodide (1 in 5), being careful that no bromine vapor escapes, and at once stopper the flask. Shake the latter thoroughly, remove the stopper and rinse it and the neck of the flask with a little distilled water, so that the washings may flow into the flask, then add 1 mil of chloroform, shake the mixture well and titrate with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 97 per cent. of C_6H_5OH.

"Each mil of tenth-normal bromine V.S. corresponds to 0.001568 Gm. of C_6H_5OH. Each gramme of Phenol corresponds to not less than 618.6 mils of tenth-normal bromine V.S." *U. S.*

For methods of assaying Phenol, see *Y. B. P.*, 1891, 190; *Chem News*, 1891, 74; *J. P. C.*, 1894, 105; *A. J. P.*, 1892, 164; *Ph. Centralh.*, 1892, 479; *D. C.*, 1896, 158; *A. J. P.*, 1898, 369.

Though nearly neutral to test paper, it combines feebly with some bases, its salts being decomposed by carbon dioxide, and those with the alkalies having an alkaline reaction. The potassium phenolate is said to be decomposed even by water. Nitric acid converts it into picric acid, for the manufacture of which it is largely used. It reduces many metallic salts, especially those of silver and copper, and co-

agulates collodion. Bromine water, added in excess of a weak solution, produces a flocculent white precipitate. This precipitate, which consists of tribromophenol, $C_6H_2Br_3.OH$, with some tribrom-phenol-bromide, $C_6H_2Br_3.OBr$, is so insoluble that it separates even in the most dilute solutions, and affords an extremely delicate test. In twenty-four hours a solution containing but 1-60,000th of phenol gives the reaction. (Allen, *Com. Org. Anal.*, 2d ed., vol. ii, p. 540.) If an aqueous solution of phenol be gently warmed with ammonia and solution of sodium hypochlorite (avoiding excess), a deep blue color is obtained, which is lasting, but turns to red on the addition of acids. Solutions containing 1 part of phenol in 5000 parts of water react well when 20 mils are employed. Much smaller quantities give the reaction after a time. (*Ibid.*, p. 539.) Ferric chloride (avoiding excess) gives a fine violet color, by which 1 part of phenol in 3000 parts of water can be detected. The presence even of neutral salts often interferes with this reaction.

The substances with which phenol is most likely to be confounded are cresol or cresylic acid and creosote, the former, like it, extracted from coal tar, the latter from wood tar exclusively. As cresol is incapable of crystallizing at ordinary temperatures, the two cannot be confounded in the solid state, and, as before observed, its presence in the liquid state is of little consequence, as its virtues are of the same kind, and at least equal. Its boiling point, however, is considerably higher than that of phenol, being about 204° C. (400° F.), and it may, therefore, be supposed to be present in any suspected liquid which will not crystallize at any common temperature, or boil under 202° C. (395° F.) to 204° C. (400° F.). It is also distinguished by being less soluble in water, ammonia water, glycerin, and solution of sodium hydroxide than is the case with phenol, but it is more soluble in petroleum benzin. (Allen.) (*A. J. P.*, Jan., 1879.) Creosote is distinguished by its lower density, its liquid form, and its higher boiling point; by its insolubility in strong ammonia water, or in 6 per cent. sodium hydroxide solution, as well as its insolubility in pure glycerin (see *Creosotum*); by not coagulating collodion and albumin; and by the different effects on it of strong nitric acid, which with phenol produces pure picric or trinitrophenic acid, and with creosote, oxalic acid, resinous matter, and but a small portion of picric acid. (Calvert, *L. L.*, 1863, p. 523.) Phenol differs also in having no effect on polarized light.

The commercial phenol powders and liquids all contain not only cresol, but also nearly inactive and valueless neutral tar oils, and it is important to be able to determine the percentage of the *tar acids* and that of simple *tar oils* in a commercial sample. John Muter (*A. J. P.*, Nov., 1887, p. 581) has worked out a simple method for this, based upon the following four observed facts: (1) Phenol, cresol, and their homologues are completely soluble when shaken up with a 5 per cent. solution of sodium hydroxide; (2) Liquefied phenol and the corresponding cresol are insoluble in a saturated solution of chloride; (3) In the presence of a sufficient excess of alkali even a largely diluted solution may be boiled down without the slightest appreciable loss of phenol or cresol; (4) Tar oils and naphthalene are only very slightly dissolved by alkali, and may be perfectly removed from the solution by agitating it with benzene.

E. W. Davy proposes, as a test for phenol, sulpho-molybdic acid, made by dissolving 1 part of molybdic acid in 10 or even 100 parts of pure concentrated sulphuric acid; 3 or 4 drops of this solution are added to the phenol placed on white porcelain; a beautiful blue coloration will be produced upon standing, particularly if the liquid be gently heated; if this reagent is applied to wood creosote in aqueous solution, a brownish-red color is produced. Phenol in creosote may be detected by distilling an aqueous solution of the mixture; the first portion of the distillate will give the reaction for creosote, the last portion that for phenol. (*P. J.*, June 22, 1878.)

Composition.—The view of the composition of phenol now universally accepted is that it is the hydroxyl (OH) derivative of benzene, C_6H_6, and its formula is $C_6H_5.OH$. This would ally it to the alcohols, and it may be compared, in fact, to what are known as *tertiary* alcohols. The *primary* alcohols, like ethyl alcohol, C_2H_5 OH, yield corresponding aldehydes and acids on oxidation. The counterpart of these in the aromatic series are the aromatic alcohols, like $C_6H_5.CH_2OH$, which yield benzoic acid, C_6H_5 COOH, on oxidation. The name *phenols* has therefore been given to these derivatives in which H of the benzene group is replaced by OH. Phenol is commonly called *carbolic acid*, but its claims to be considered as an acid are very feeble, as, though it combines with salifiable bases, it is incapable of neutralizing the alkalies, does not affect the color of litmus, and may be separated from its combinations with great facility, sometimes, it is asserted, even by water. Shaken in the liquid form with one-fourth of water, and cooled at 4.5° C. (40° F.), it crystallizes in the form of a hydrate, $C_6H_5.OH + H_2O$, which fuses at 17° C. (62.6° F.).

Uses.—Pure phenol is locally irritant, anesthetic and mildly caustic. When applied undiluted to the skin or mucous membrane it causes a sharp pain, followed by numbness, and accompanied by a whiteness and corrugation of the surface due to coagulation of albumen. In dilute solution, up to 3 or 4 per cent., it is only mildly irritant but is actively anesthetic and germicidal. In appropriate strengths phenol is a rapid and certain destroyer of the vegetative forms of bacteria, but against the more resistant spores it is comparatively useless. A 1 per cent. solution will destroy non-sporulating

micro-organisms after sufficiently prolonged exposure, and a 2 per cent. solution promptly. On the other hand, the anthrax spores are not killed with certainty even after twenty-four hours' exposure to a 5 per cent. solution. It is antiseptic—that is, inhibits the multiplication of bacteria—when present in the proportion of about 1 to 800. Its peculiar value as a germicide is due largely to the fact that its activity is but slightly diminished by the presence of albuminous material. Although in sufficient concentration phenol precipitates albumen, it does not do so by forming chemical union with it, as does bichloride of mercury, but by changing the character of the solvent; the precipitation is analogous to that which takes place when water is added to an alcoholic solution of resin. Partly because of the widespread familiarity with phenol and partly for certain technical reasons it has been adopted by the United States Government as a standard for comparison of disinfectant power. The *phenol coefficient* of the United States Government (*Hygienic Lab. Bulletin* No. 82, April, 1912) represents the amount of phenol required to exercise the same degree of germicidal action against the typhoid bacillus, under certain standard conditions of testing, as one part of the disinfectant to be tested; for instance, if disinfectant X has a phenol coefficient of 2 that means that it would require 2 parts of phenol to equal one of X, or in popular parlance that X is twice as strong as phenol; a phenol coefficient of 0.5 means that the disinfectant is only one-half as active as phenol.

Phenol is widely used as a disinfectant not only for sanitary but for surgical and medical purposes. For the disinfection of the surgeon's hands its local anesthetic action is a great disadvantage and its uncertain effect upon sporulating organisms almost excludes its use for the disinfecting of surgical instruments. As a dressing for *wounds* it is, however very widely employed. In *burns* and other painful *ulcerations* its local anesthetic action often makes it peculiarly valuable. When applied continuously for several days it in some way interferes with the nutrition of the part, and a number of cases of local gangrene have followed the use of phenol dressings. Chlunsky (*Cb. I. M.*, 1912, p. 226) asserts that the addition of camphor lessens the caustic action of phenol and has employed a mixture containing 30 parts of phenol, 60 of camphor, and 10 of alcohol, as a local application in the treatment of *erysipelas*. This *phenol-camphor* (which is also known under the name of *kamphenol* and *erypol*), has also been used by a number of surgeons as a local application to infected *wounds, furuncles,* and as an injection into *cold abscesses,* with asserted excellent results. According to Horowitz (*D. M. W.*, 1913) the diminution of the corrosive action of the phenol is due to the action of the alcohol rather than to the camphor. Phenol is also used to a large extent in the form of oily or watery solutions in the treatment of *coryza, stomatitis,* and other infected conditions of the mucous membranes.

For ordinary surgical purposes it may be used in strengths of from 3 to 5 per cent. The liquid phenol is often applied undiluted as a germicide and caustic in badly infected wounds. Various fabrics are impregnated with phenol for surgical use.

Lister's gauze may be made by soaking a loose cotton cloth with a mixture of 5 parts rosin, 7 parts paraffin, and 1 part phenol. Bruns improves upon this, making a more flexible dressing, by dissolving 400 grammes of powdered rosin in 2 liters of alcohol, adding 40 grammes of castor oil and 100 grammes of phenol; this will impregnate 2 pounds of the gauze, which is to be dried by spreading it out in the air. (See also Lund's process, *A. J. P.*, Feb., 1874.) *Carbolized jute* may be made by Rosenwasser's process by soaking in a percolator 1 pound of jute with a solution of crystallized phenol 700 grains, paraffin 700 grains, rosin 2800 grains, petroleum benzin 3 pints. (*A. J. M. S.*, 1879, p. 458. See also *N. R.*, April 1879, and April, 1880.) For burns and scalds 1 part of phenol in 6 parts of olive oil may be applied on lint. For the dressing of *cancerous* and other foul *ulcers,* a cerate (ten grains to the ounce) may be used. There is an official ointment.

Phenol is frequently employed as an antiseptic in various forms of gastro-intestinal affections. Because of the rapidity of its absorption as well as the relatively large dose which would be required, it is doubtful whether it exercises any efficient action in the intestines, but in fermentative *gastritis* it is often a useful remedy. It is also of service in *nervous vomiting,* and in *gastrodynia* for its local anesthetic action upon the mucous membrane of the stomach. Externally it is of much service as a local anesthetic in *urticaria, sunburn,* and other conditions attended with *itching* or burning of the skin.

The hypodermic injection of phenol has been highly lauded by Baccelli in the treatment of *tetanus* and his recommendations have had many followers. The method consists in injecting hypodermically two or three mils (30–45 minims) of a 2 per cent. solution every two or three hours, a total dose of 0.5 to 1.5 Gm. (eight to twenty-three grains) of phenol being given in the twenty-four hours. Baccelli has collected from his own experience and the literature, over three hundred cases treated by this method with a mortality of about 10 per cent.

Phenol Poisoning.—Because of the ease with which it is obtained and the rapidity and certainty of its effects, phenol is a very frequently used poison for suicidal purposes, and cases of accidental poisoning are also quite common. The symptoms usually develop very rapidly; indeed death has occurred in 2 or 3 minutes, the patient dying in immediate coma and col-

lapse. After small amounts the symptoms are nausea and vomiting, collapse with pallor and cold sweats, feeble pulse, stupor deepening into complete insensibility and disturbances of the breathing, the respirations are usually hurried and shallow, often irregular and sometimes paroxysmally arrested. There is usually paralysis of both sensation and motion, but in some cases violent epileptiform convulsions have occurred. The urine is generally scanty and albuminous and of a greenish or blackish color. The diagnosis is usually not difficult, being made upon the odor, the smoky urine, and the presence of white corrugated spots in the mucous membrane of the mouth or throat. The ordinarily fatal dose of phenol is about half an ounce, but De Vries (*Th. M.*, 1890, iv, p. 644), has reported death in a woman from 22 grains. On the other hand, recovery has followed after the ingestion of an ounce. In the fatal cases death usually occurs in less than 2 hours from respiratory failure, although in some instances weakness of the heart has been the cause of the lethal termination. In the treatment of carbolic acid poisoning the stomach should be immediately emptied, preferably by means of the stomach pump. There is no known efficient chemical antidote. Because of the fact that phenol unites in the body with sulphuric acid, being eliminated as a phenol-sulphonate, the sodium sulphate was at one time routinely employed in carbolic acid poisoning, but the latest investigations throw grave doubt upon its efficacy. Alcohol has also been recommended on the grounds that it lessens the caustic action of the poison, but the effects of alcohol are due simply to the fact that phenol is rapidly soluble in this fluid and is therefore immediately diluted; while alcohol is useful to prevent external burns by phenol and may be of service for the purpose of washing out the stomach, it has no real antidotal properties. The best method of treating phenol poisoning is to wash the stomach out with diluted whiskey or 25 per cent. alcohol, and afterwards with water, and the administration of strychnine and other stimulants to combat the depressant action on the vital centers. Magnesium sulphate may be administered for the purpose of emptying the intestinal tract as well as in the hope, rather than the expectation, that it may exercise some antidotal influence.

Dose, one to three grains (0.065–0.2 Gm.).

* "Phenol, *a convenient quantity;* Distilled Water, *a sufficient quantity.* Liquefy the phenol by placing the unstoppered container in a water bath, and applying heat gradually until the crystals have melted; transfer the liquid to a tared vessel and weigh it; then add for each *nine grammes* [or 139 grains] of phenol *one gramme* [or 15 grains] of distilled water and mix thoroughly. Preserve it in well-closed containers, protected from light." *U. S.* "Phenol, 100 *grammes;* Distilled Water, sufficient to produce 115 *grammes.* Mix." *Br.*

It is officially described as "a colorless liquid, which may develop a red tint upon keeping. It has a characteristic, somewhat aromatic odor. When undiluted it cauterizes and whitens the skin and mucous membrane. Liquefied Phenol is miscible with alcohol, ether, or glycerin. When it is diluted with an equal volume of glycerin, the mixture is miscible with water. Specific gravity: about 1.065 at 25° C. (77° F.). When subjected to distillation, the boiling point does not rise above 182° C. (359.6° F.). In other respects Liquefied Phenol responds to the tests for identity and purity under *Phenol* (omitting the congealing point).

"**Assay.**—Proceed as directed under *Phenol.*

"Each gramme of Liquefied Phenol corresponds to not less than 554.8 mils of tenth-normal bromine V.S." *U. S.*

"A liquid, at first colorless, but usually acquiring a pinkish hue. Forms a clear solution on the addition of 12 to 20 per cent. by weight of *water* at 15.5° C. (60° F.). Specific gravity 1.067 to 1.069. Boiling point gradually rising to a temperature not higher than 183° C. (361.4° F.)." *Br.*

Peter Boa prefers to re lace a portion of the water used for liquefying the phenol with alcohol, and he found the following mixture to remain fluid even at a temperature of 4.5° C. (40° F.); 100 parts of phenol, 7½ parts of water, and 2½ parts of alcohol.

Dose, one to three minims (0.06–0.2 mil).

PHENOLPHTHALEINUM. U. S., Br.

PHENOLPHTHALEIN Phenolphthal.

(phē-nŏl-phthă-lę-ĭ'nŭm)

"A dibasic phenol derivative (dihydroxyphthalophenone) [$C_{20}H_{14}O_4$ or $(C_6H_4OH)_2CO.C_6H_4CO = 318.11$]." *U. S.* "Phenolphthalein,

or dihydroxy-diphenyl-phthalide, $C_{20}H_{14}O_4$, may be obtained by heating phenol with phthalic anhydride and sulphuric acid, and purifying the product." *Br.*

Phenolphthalein is made by heating phenol, 10 parts, phthalic anhydride, 5 parts, and sulphuric acid, 4 parts, for a number of hours to 120° C. (248° F.). The sulphuric acid acts merely as a dehydrating agent and is subsequently removed by washing with water. The crude phenolphthalein is subsequently purified by dissolving in an alkali, precipitating with an acid and then dissolving in alcohol and decolorizing with animal charcoal. It may be recovered from the alcohol by evaporation or precipitated by diluting the solution with water. The reaction for its formation is as follows:

$$2C_6H_5OH + C_6H_4(CO)_2O = (C_6H_4OH)COC_6H_4CO + H_2O$$

It is officially described as follows: "Phenolphthalein occurs as a white or faintly yellowish-white, crystalline powder, odorless and tasteless; permanent in the air. One Gm. of Phenolphthalein dissolves in 13 mils of alcohol, and in about 70 mils of ether at 25° C. (77° F.); almost insoluble in water. Melting point: not below 253° C. (487.4° F.). It is dissolved by solutions of the alkali hydroxides and carbonates with a red color. The solutions are decolorized by the addition of acids in excess or by heating with zinc dust. Incinerate about 2 Gm. of Phenolphthalein; not more than 0.05 per cent. of ash remains. A solution of 0.5 Gm. of Phenolphthalein in 30 mils of alcohol is colorless. One-half Gm. of Phenolphthalein dissolves completely in a mixture of 4 mils of sodium hydroxide T.S. and 50 mils of distilled water (*fluorane*). A mixture of 250 mils of cold, recently boiled, distilled water and 0.5 mil of a solution of Phenolphthalein (1 in 100) in diluted alcohol requires not more than 0.5 mil of hundredth-normal potassium hydroxide V.S. to produce a pink coloration. Heat about 0.5 Gm. of Phenolphthalein on a water bath for five minutes with 10 mils of diluted hydrochloric acid, filter the liquid and evaporate the filtrate to dryness; the residue, when dissolved in 25 mils of distilled water, slightly acidulated with hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Heat a crucible to redness and introduce, in small portions, an intimate mixture of 0.2 Gm. of Phenolphthalein, about 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous sodium carbonate. Maintain a red heat until the reaction ceases, then boil the cooled residue for five minutes with 10 mils of diluted sulphuric acid, filter, and wash the undissolved residue with 10 mils of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve. The residue, dissolved in 5 mils of distilled water, meets the requirements of the Test for arsenic (see Part III, Test No. 1)." *U. S.*

"A white, or yellowish-white, crystalline or amorphous powder. No odor or taste. Soluble in *alcohol* (90 per cent.), the solution being colorless. Almost insoluble in *water*, but soluble in *solution of sodium hydroxide*, forming an intensely red liquid. Melting point 250° to 253° C. (482°–487.4° F.). Not more than 0.1 millilitre of *N/10 solution of sodium hydroxide* is required to produce a red coloration in 250 millilitres of recently boiled and cooled *water* to which has been added 0.5 millilitre of a solution (1 in 100) of Phenolphthalein in *alcohol* (60 per cent.). No appreciable ash." *Br.*

A derivative of phenolphthalein known as *phenolsulphonephthalein*, is used in the form of a monosodium derivative as a test of renal function. It consists of a bright red, crystalline powder, slightly soluble in water, with the formation of a yellow solution which is turned red or purple by alkalies. It is marketed in ampuls, each one of which holds an amount sufficient for a test. It is administered hypodermically and the urine is collected for one hour thereafter and tested quantitatively by adding an alkali and matching the shade of the solution colorimetrically with standards. The normal kidneys excrete from 40 to 60 per cent. of the ingested amount within one hour, irrespective of the amount of urine voided.

Uses.—The discovery that phenolphthalein possessed cathartic properties was made accidentally; it was used in Hungary as a means for the ready identification of artificial wines, and the observation that these wines were laxative led to an investigation of its properties. H. C. Wood, Jr. (*J. A. M. A.*, 1911, liv, p. 348) has found that it increases intestinal secretions, and that, when given intravenously to dogs in doses equivalent to 60 grains for a man, it produced no change in circulation or respiration. According to Berthomeau and Daguin (*Press Med.*, 1908, xvi, p. 378), the cathartic effects are due to combined stimulation of secretion and peristalsis. Although it seems to be slightly irritant to the kidneys, when introduced into the blood stream there is little danger of this action because its slight absorbability by the bowel.

Hydrick (*J. Bi. Chem.*, 1914, xvii) found albuminuria in every one of twenty experiments after the administration of 1 to 2 grain doses of phenolphthalein, but the results are so contrary to common experience that one is tempted to doubt the accuracy of his observations. Orland (*Med. Klin.*, 1913, p. 257) reported a case of a child aged three years who took 1.8 Gm. (27 grains) in the form of tablets with no more serious effect than violent purgation. The urine for four days showed the presence of phenolphthalein, but showed neither albumin nor sugar.

Phenolphthalein is a mildly acting cathartic, usually requiring from 4 to 8 hours for catharsis, and producing large, soft discharges without much gripeing. Although when used continuously the alimentary canal seems to become accustomed to it, it is nevertheless useful

as a variant from the vegetable laxatives in chronic as well as in the more occasional types of *constipation.*

Dose, one-half to three grains (0.032–0.2 Gm.).

Off. Prep.—Trochisci Phenolphthaleini, *N. F.*

PHENYLIS SALICYLAS. U. S. (Br.)

PHENYL SALICYLATE Phenyl. Salicyl. [Salol, Pharm. 1890]

(phē'nȳl-ĭs săl-ĭ-cȳ'lăs)

"The phenyl ester [$C_{13}H_{10}O_3$ or $C_6H_4(OH)COOC_6H_5$ 1:2 = 214.08] of salicylic acid. Preserve it in well-closed containers in a cool place." *U. S.* "Salol, or phenyl salicylate, $C_{13}H_{10}O_3$, may be obtained by the interaction of salicylic acid and phenol." *Br.*

Salol, *Br., U. S.* 1890; Salicylate de Phénol, Salicylate de Phényle, *Fr. Cod.;* Phenylum salicylicum, *P. G.;* Phenylsalicylat, Salicylsaurephenylester, *G.;* Salol, *It.;* Salicilato de fenol, *Sp.*

Preparation.—*Phenyl salicylate* was first produced by Nencki, of Basel, and introduced to the medical profession by Sahli, of the same place. It is prepared by heating salicylic acid with phenol in the presence of phosphorus pentachloride or phosphorus oxychloride; the action dehydrates and withdraws the elements of water, and unites the phenyl group with the salicylic acid radical. According to Ernert, nearly the theoretical yield of phenyl salicylate may be obtained by heating salicylic acid to a temperature between 160° and 240° C. (320° and 464° F.), and preventing the access of air while water is being disengaged; it is probable that salicylic anhydride is formed, and the phenyl resulting from its decomposition combines with unaltered salicylic acid to produce phenyl salicylate according to the following reaction:

$$2C_6H_4OHCOOH = (C_6H_4OHCO)_2O + H_2O$$

Then

$$(C_6H_4OHCO)_2O = C_{13}H_{10}O_3 + CO_2$$

Properties.—It is described as "a white, crystalline powder, having an aromatic odor and a characteristic taste. One Gm. of Phenyl Salicylate dissolves in 6670 mils of water and in 6 mils of alcohol at 25° C. (77° F.); very soluble in chloroform, ether, benzene, or in fixed or volatile oils. It melts between 41° and 43° C. (105.8° and 109.4° F.). The addition of diluted ferric chloride T.S. to an alcoholic solution of the salt (1 in 20) produces a violet color. Dissolve from 0.2 to 0.3 Gm. of Phenyl Salicylate in 2 mils of hot sodium hydroxide T.S., and acidify the solution with hydrochloric acid; salicylic acid separates and the odor of phenol is recognizable. Incinerate about 2 Gm. of Phenyl Salicylate; not more than 0.05 per cent. of ash remains. Phenyl Salicylate does not redden moistened blue litmus paper (*free acids*). Shake about 1 Gm. of Phenyl Salicylate with 50 mils of distilled water and filter the liquid; the addition of 1 drop of ferric chloride T.S. to 10 mils of the filtrate produces no violet color (*uncombined phenol or salicylic acid*). Ten mil portions of the same filtrate tested separately with barium nitrate T.S. and silver nitrate T.S. show no turbidity (*sulphate or chloride*)." *U. S.*

"Colorless crystals, or crystalline powder. Aromatic odor; taste slight. Almost insoluble in *water;* soluble in 15 parts of *alcohol* (90 per cent.), in 0.3 part of *ether* or of *chloroform,* and in fixed and volatile oils. Melting point from 42° to 43° C. (107.6°–109.4° F.). Alcoholic solution neutral to *litmus;* yields a white precipitate with *solution of bromine,* and a violet coloration with dilute *T. Sol. of ferric chloride.* When 0.2 gramme is boiled with 5 millilitres of *solution of sodium hydroxide,* and the cooled solution acidified with *hydrochloric acid,* the odor of phenol is developed and a crystalline precipitate is formed. *Water* which has been shaken with Salol is not affected by *T. Sol. of ferric chloride* (absence of free salicylic acid and of readily soluble salicylates), and yields no characteristic *reactions* for sulphates or chlorides. No appreciable ash." *Br.*

Uses.—In the small intestine phenyl salicylate is broken up by the pancreatic juice, and yields about thirty-six per cent. of phenol and sixty-four per cent. of salicylic acid. The completeness and rapidity of this action depend upon the amount of phenyl salicylate ingested and the alkalinity of the juice in the intestines. The change is, however, sufficient, when phenyl salicylate is freely given, for the production of salicylic acid intoxication, and for the blackening of the urine with educts from phenol. Because this change occurs in the intestines somewhat slowly, the remedy has been used as an internal antiseptic in the treatment of *enteritis* and *intestinal fermentation,* but its value is questionable. It has been largely used in *rheumatism* as a substitute for salicylic acid, but it is much less prompt and certain in its action than is that remedy. Moreover, on account of the large proportion of phenol which it contains, it is much more dangerous than the corresponding dose of salicylic acid. Hesselbach has shown that it is prone to affect the secreting structure of the kidneys, and two fatal cases of poisoning by it have been reported. (*L. L.,* May, 1891.) It is especially dangerous when the kidneys are diseased. Phenyl salicylate is used as a test of gastric motility, the time required for the appearance of salicylic acid in the urine depending largely upon the rapidity with which it passes out of the stomach. It has also been employed as a surgical dusting powder on the basis that it will be slowly decomposed by the wound secretions, liberating its antiseptic constituents.

Dose, from five to fifteen grains (0.32–1.0 Gm.).

PHOSPHORUS. U. S., Br.

PHOSPHORUS Phosphor.

(phŏs'phọ-rŭs)

"Phosphorus [P = 31.04] must be carefully preserved under water, in strong, well-closed containers, in a secure and moderately cool place, protected from light." *U. S.* "Phosphorus is a solid non-metallic element. It may be obtained from calcium phosphate." *Br.*

Phosphore, *Fr. Cod.*; Phosphorus, *P. G.*; Phosphor, *G.*; Fosforo, *It., Sp.*

This non-metallic element was discovered in 1669 by Brandt, an alchemist of Hamburg, who obtained it from evaporated urine by a process which remained a secret until 1737. As thus procured, it was exceedingly scarce and costly. In 1769 the Swedish chemist Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted.

Preparation.—Powdered calcined bones (calcium bone phosphate) are digested for twenty-four hours with two-thirds of their weight of sulphuric acid previously diluted with twelve times its weight of water. The sulphuric acid separates the greater part of the lime from the phosphoric acid, and precipitates as calcium sulphate, while an acid calcium phosphate, $Ca H_4(PO_4)_2$, remains in solution. The liquid is then strained through a linen cloth to separate the calcium sulphate, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, to be separated by a new straining. The strained solution is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a mass, which is dried by being heated to dull redness. At this temperature the acid phosphate is changed into metaphosphate, $Ca(PO_3)_2$, by the loss of two molecules of water. The mass when cool is quickly transferred to a coated earthenware retort, furnished with an adapter of copper, bent downward at right angles, so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adapter. The bottle is closed round the adapter with a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water, and this takes place generally for from twenty-four to thirty hours. During this part of the process the metaphosphate is decomposed, its oxygen combining with the charcoal, and the liberated phosphorus distilling over. The calcined bones of the sheep are preferred, as they contain the largest proportion of calcium phosphate and are most readily acted on by the acid. In the process as described, only two-thirds of the phosphorus is set free, the remainder being still combined. If, however, silica is added to the mixture before the distillation, all the phosphorus is liberated.

The manufacture of phosphorus by the use of the electric furnace, first brought out by Readman and Parker some years ago, has now practically displaced the older methods for the production of phosphorus. Albright and Wilson, who formerly manufactured phosphorus by the distillation method at Oldbury, England, have built works at Niagara Falls, and practically control the production by the electric furnace method in the United States and England.

A mixture of calcium phosphate, carbon, and sand or kaolin is submitted to the temperature of the electric arc while packed in a covered plumbago crucible. The phosphorus is then distilled off in a current of an inert gas. It is very pure, and it is claimed that 86 per cent. is recovered. The native Redonda phosphate, an aluminum phosphate, is also taken for this process instead of the calcium phosphate, and phosphorus obtained from it without any previous purification. The great bulk of the phosphorus is consumed in the manufacture of matches, a smaller amount in the production of phosphor bronze, and another portion in making the chemical compounds of the element. The present annual production (1906) is about 3000 tons, produced in three factories: Oldbury in England, Lyons in France, and Niagara Falls in the United States.

Properties.—Phosphorus is a semi-transparent solid, without taste, but possessing an alliaceous odor. When perfectly pure it is colorless, but as usually prepared it is yellowish or reddish yellow. It is flexible, and when cut exhibits a waxy luster. It was said by Boettger to be easily pulverizable by agitation with a solution of urea. (*J. P. C.*, June, 1863, p. 488.)

"Phosphorus is a translucent, nearly colorless solid, of a waxy luster, having at ordinary temperatures about the consistence of beeswax. By long keeping the surface becomes white or red, and occasionally black. It has a distinctive and disagreeable odor and taste, *but should not be tasted, except in very dilute solution.* When exposed to the air, it emits white fumes, which are luminous in the dark, and have an odor somewhat resembling that of garlic; on longer exposure to the air, it often takes fire spontaneously. Specific gravity: about 1.830 at 10° C. (50° F.). It melts at about 44° C. (111.2° F.). One Gm. of Phosphorus dissolves in about 400 mils of dehydrated alcohol, about 17 mils of chloroform, 102 mils of absolute ether, 31.5 mils of benzene, and in 0.9 mil of carbon disulphide at 25° C. (77° F.), sparingly soluble in fixed oils. It is almost insoluble in water, to which it imparts its characteristic disagreeable odor and taste. Add 1 Gm. of Phosphorus to 10 mils of nitric acid, diluted with 10 mils of distilled water, in a flask having a capacity of 50 mils, and digest the mixture at a gentle heat on a water bath until the

Phosphorus is dissolved, passing a current of carbon dioxide into the flask over the surface of the liquid during the heating. Transfer this solution to a dish, evaporate it until nitrous vapors are no longer given off, and then dilute the solution to 250 mils with distilled water. One mil of this solution meets the requirement of the Test for arsenic (see Part III, Test No. 1). Add barium chloride T.S. to another portion of the latter solution; not more than a slight opalescence is produced (*sulphur*)." *U. S.*

"A semi-transparent, wax-like solid, which emits white vapors and is luminous in the dark when exposed to the air. Insoluble in *water;* soluble in 350 parts of *absolute alcohol,* in 80 parts of *olive oil,* in 80 parts of *ether,* in 25 parts of *chloroform,* and in 0.5 part of *carbon disulphide.* Soft and flexible at ordinary temperatures. Melting point 44° C. (111.2° F.). Ignites in the air at a temperature a little above its melting point, burns with a luminous flame and produces dense white fumes. 1 gramme is slowly attacked and finally dissolved without residue when boiled with 10 millilitres of *nitric acid* diluted with an equal volume of *water,* and the resulting solution yields not more than the slightest *reaction* for sulphates." *Br.*

Its pulverization may be readily effected by melting it in hot water, and agitating until it is thoroughly cooled, and the powder is obtained finer in saline solutions than in pure water.

According to Flückiger, carbon disulphide is capable of dissolving twenty times its weight of phosphorus without losing its fluidity.

Phosphorus boils at 287.7° C. (550° F.), air being excluded. During its combustion it combines with the oxygen of the air, and forms phosphoric oxide. On account of its great inflammability, it must be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapors, which are luminous in the dark. It sometimes contains arsenic, and therefore, when used in forming medicinal preparations, should be tested for that metal. C. J. Rademaker obtained out of 100 parts of phosphorus about one part of arsenic. (*A. J. P.,* Nov., 1870.) It occasionally contains antimony or sulphur, the latter rendering it brittle.

When phosphorus is kept in ordinary water it becomes covered with a whitish layer, of the nature of which there are different opinions, it being looked upon by some as a phosphorus hydrate, by others as an allotropic condition of that element, and by others again as a partial crystallization, but all these opinions have apparently been disproved by Ernest Baudrimont, who seems to have demonstrated that *white phosphorus* is entirely identical with this whitish layer in its ordinary state, and results from a kind of erosion of the surface, owing to partial oxidation by the free oxygen held in solution by the water. The change never takes place in water entirely deprived of air, and the water when it has taken place holds phosphorous acid in solution. (*J. P. C.,* 4e sér., iii, 17, 1866.)

Schroetter, of Vienna, discovered an allotropic form of phosphorus, which he called *red* or *amorphous phosphorus.* It is formed when ordinary phosphorus is kept long at a temperature between 215° C. (419° F.) and 250° C. (482° F.), in atmospheres which have no action on it, or in closed glass tubes. Red phosphorus is much more indifferent than the ordinary substance, and is denser, its sp. gr. being 2.11. It is much less easily acted on by the air than ordinary phosphorus, and is insoluble in carbon disulphide, alcohol, and ether, in all of which ordinary phosphorus is soluble. Solidified from the fused state, it is brittle, and breaks with a conchoidal fracture. Its hardness is considerable. Obtained by distillation in a non-acting gas, it is mixed with ordinary phosphorus, from which it may be freed by carbon disulphide, which dissolves the ordinary variety and leaves the allotropic as a deep red amorphous powder. It may also be purified by shaking it with a solution of calcium chloride of a density intermediate between that of red and that of ordinary phosphorus, and with a little carbon disulphide. The red variety will sink to the bottom, and the ordinary float on top of the solution, dissolved in the disulphide. (E. Nicklés.) Red phosphorus when pure is not poisonous. This has been proved beyond a doubt by the experiments of Reynal and Lassaigne and of L. Orfila and Rigaut. It is applicable to the manufacture of lucifer matches, and forms a much safer material than ordinary phosphorus. It does not take fire by friction at common temperatures, and therefore may be transported with the greatest safety. It has been said to be unchangeable in the air but this is not exactly true, as proved by an observation of T. B. Groves, who, having set aside some red phosphorus in a bottle that was not air tight observed for a year or more no visible change, but found at length that oxidation had taken place, with the result of forming a large quantity of phosphoric and phosphorous acids, in the proportion of 5 molecules of the former to 2 of the latter. (*P. J.,* June, 1865, p. 621.) Besides the white and red forms of phosphorus, there is another, called the *black,* first noticed by Thènard and investigated by Blondlot, who found that it is pure phosphorus, and that its production is owing to some modification in the mode of cooling, when it has been in the liquid state. (*J. P. C.,* 1865, 4e sér., i, 407.) Flückiger doubted the existence of black phosphorus, however, and, after an investigation, states that the black color is due to arsenical contamination. (*Chem. Ztg.,* 1892, 181.)

Still another modification of phosphorus has been made known by Hittorf, who obtained it by heating red phosphorus and lead together in a closed vessel. The lead on melting dissolved the phosphorus, and on cooling deposited it in the state of black crystals resembling the crys-

tals of arsenic. In this form, phosphorus is a conductor of electricity, and its sp. gr. at 16.6° C. (62° F.) is 2.34. Hittorf distinguishes it by the name of *metallic phosphorus,* and ranks it in the same category with red phosphorus, the latter differing simply in being amorphous. (*Chem. News,* March 23, 1866, p. 133.) Blondlot has succeeded in crystallizing common phosphorus by means of sublimation, operating in an atmosphere of nitrogen. (*J. P. C.,* 4e sér., iv, 321.)

Phosphorus forms with oxygen two oxides, *phosphoric,* P_2O_5, and *phosphorous,* P_2O_3. Corresponding to the first of these are three acids, known as *orthophosphoric* (tribasic phosphoric), H_3PO_4, *pyrophosphoric,* $H_4P_2O_7$, and *metaphosphoric,* HPO_3. The first of these is formed by dissolving P_2O_5 in boiling water, or by the action of nitric acid upon phosphorus itself; the second by the heating of the tribasic phosphoric acid to 213° C. (415.4° F.); and the third by the ignition of the tribasic variety, or by dissolving P_2O_5 in cold water. To the second oxide corresponds *phosphorous acid,* H_3PO_3, although it cannot be formed directly from the oxide. This is a dibasic acid, containing one hydrogen atom not replaceable by metal. To the hypothetical *hypophosphorous oxide,* P_2O, corresponds *hypophosphorous acid,* H_3PO_2. It is monobasic, containing two hydrogen atoms which are not replaceable by metal.

Phosphorus is frequently used as an ingredient in rat pastes. A method for the determination of the free phosphorus in such preparations as well as in the phosphoretted resin, tablets, pills, etc., has been described by E'we and Vanderkleed (*J. A. P. A.,* 1914, p. 1684), in which the phosphorus is distilled in an atmosphere of CO_2, and the distillate collected in a silver nitrate solution and the resulting silver compound decomposed and the phosphorus estimated in the ordinary manner.

Uses.—The continued use of small doses of phosphorus stimulates the blood-making organs, but especially the growth of bone. When administered to growing animals the spongy tissue of the bone becomes thickened and the compact tissue more dense. There is some evidence also that it has a tonic effect upon the nervous system. Phosphorus is used in medicine in the treatment of diseases of the osseous tissues, such as *rickets, ununited fracture,* and *osteomalacia.* It is also widely employed in corections of nervous exhaustion, such as *neurasthenia* and some types of *neuralgia.* It is even believed by some to be of service in degenerative conditions of the nervous system, and has been used in *brain softening,* but with less positive results. Leubuschur (*M. M. W.,* 1913, xxx, p. 494), lauds it in the management of *epilepsy.* It has also been asserted to be of benefit in certain *skin diseases,* notably *acne, psoriasis,* and *chronic eczema.*

Phosphorus Poisoning.—Phosphorus is a very virulent poison, as little as one-eighth of a grain having proven fatal, and an infant was killed by eating the heads of two friction-matches. The symptoms usually do not manifest themselves until some hours after the ingestion of the phosphorus. General malaise then becomes very pronounced, and is soon accompanied by nausea, abdominal pain, and vomiting of food, mucus, and bile. On the second and third day the vomiting is likely to cease, but the abdominal tenderness remains, and there is some fever. Later the patient becomes jaundiced and severe vomiting of a coffee-ground liquid, free from bile and similar to the black vomit of yellow fever, may set in; the urine is scanty and albuminous, often with tyrosine and leucine in it, or it may finally be suppressed. Frequently there is wild delirium. The temperature falls markedly, and the patient sinks into a coma which ends in death. After death a peculiar fatty degeneration is found affecting almost all the soft tissues. The parts which suffer first are the liver, the gastro-intestinal mucous membrane, and the kidneys. Both in its symptoms and in its lesions phosphorus poisoning so closely resembles acute atrophy of the liver that only by detecting the phosphorus in the matters vomited, in the excretions, or in the tissues of the body, can a positive diagnosis be made. As the phosphates are normally abundant in the urine it is necessary to find the phosphorus in the elemental state.

For methods of detecting phosphorus in cases of suspected poisoning, see *U. S. D.,* 19th ed., p. 935.

E. Mitscherlich gave the following as a delicate test for phosphorus. The suspected substance is distilled with sulphuric acid and water from a flask, by means of a tube bent twice at right angles, into a vertical cooling-tube, passing through the bottom of a wide glass cylinder filled with water, which is constantly kept cold by passing cold water in at the bottom, while the warm water escapes at the top. Under the cooling-tube is placed a vessel to receive the distillate. If phosphorus is present, its vapor, mixed with steam, distils over, and gives rise to a distinct luminous appearance, visible in the dark, at the point where it enters the cold part of the cooling-tube.

This test while very sensitive is interfered with by a variety of substances notably iodine, calomel, corrosive sublimate, alcohol, and oil of turpentine. It acts well in the presence of fatty matters, as has been shown by de Vrij, but Roussin finds that the presence of free butyric acid prevents the luminous appearance of the phosphorus. After neutralizing with potassium carbonate, however, it can be seen. (Sonnenschein, *Gerichtl. Chem.,* 1881, p. 27.) L. Hofmann gives the following method of detecting phosphorus in the viscera in cases of poisoning. The viscera, mixed with water and a little sulphuric acid, are distilled until two drachms of liquid are obtained; to this a few drops of ammonium sulphide (ammonium sulphydrate) are

to be added, and the liquid is to be evaporated to dryness in a porcelain dish. If phosphorus be present in the minutest quantity, a drop of solution of ferric chloride will produce a deep violet and brownish, though evanescent, color. (*Chem. News,* Feb. 3, 1865, p. 53.) In addition to Mitscherlich's test, Dusart's is also used. This consists in passing pure hydrogen gas, evolved in a separate vessel, through the solution supposed to contain phosphorus, which solution has been previously warmed to about 50° C. (122° F.). The gas then is allowed to issue from a fine jet and is lighted. If phosphorus be present, the flame will show a green color in the center.

It is evident from the widespread lesions caused by phosphorus that after its absorption no treatment can be of service. It is therefore of the utmost importance that chemical antidotes and emetics be used promptly. Probably the best chemical antidote is potassium permanganate, which acts by oxidizing the poison, but copper sulphate is of great value as it not only forms a non-toxic phosphide of copper but also acts as an emetic. The oil of turpentine has been stated to possess antidotal properties, but this is not true of the American oil. If the stomach tube be at hand probably the best treatment is washing out the stomach with a one-half per cent. solution of potassium permanganate repeatedly and leaving about half a pint of the solution in the stomach. In the absence of the stomach pump, three grains of copper sulphate may be given every five minutes until free emesis, and after the stomach has been thoroughly emptied a dose of four grains of potassium permanganate should be given. Formerly workers in match factories were frequently attacked with a peculiar form of chronic phosphorus poisoning of which the most characteristic symptom was a necrosis of the jaw, whence the popular name of "phossy jaw." Since the introduction, however, of the harmless sesquisulphide this condition has become much less common. The safety matches do not contain ordinary or yellow phosphorus, an igniting composition containing red phosphorus, which when pure is harmless, being painted on the box. The use of the poisonous forms of phosphorus in matches is now prohibited by law in this and most civilized countries.

Phosphorus should never be exhibited in substance, but the official pill is an eligible preparation. The phosphorated oil (*Br.* and *U. S. P.,* 1890) is also a useful means of administering the drug.

The allotropic red phosphorus sometimes called *amorphous phosphorus,* is non-toxic. It has been suggested for therapeutic purposes but appears to be quite inert.

The *elixir* (*Elixir Phosphori,* N. F. IV) is probably the most eligible of the liquid preparations, but the *oil* (*Oleum Phosphoratum,* N. F. IV) is very efficient, as is also the official pill (*Pilulæ Phosphori*). Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance.

Dose, of phosphorus, from 1-100th to 1-80th of a grain (0.0006–0.0008 Gm.). Much larger doses than these have been given, but have in various cases produced unpleasant symptoms.

PHYSOSTIGMA. U. S.

PHYSOSTIGMA Physostig. [Calabar Bean, Ordeal Bean]

(phȳ-sọ-stīg'mą)

"The dried ripe seeds of *Physostigma venenosum* Balfour (Fam. *Leguminosæ*), yielding not less than 0.15 per cent. of the alkaloids of Physostigma." *U. S.*

Physostigmatis Semina, *Br.* 1898; Chopnut; Ordeal Bean of Calabar; Faba Calabarica; Fève du Calabar, *Fr. Cod.;* Kalabarbohne, *G.;* Haba del calabar, Eseve, *Sp.*

Physostigma venenosum is a climbing plant, with a ligneous stem, and frequenting especially the banks of streams, into which it often drops its fruit when ripe, and it is said that the people of Calabar derive their supply principally from the borders of the streams down which the fruits are carried. The rhizome is spreading, with numerous rootlets, often having attached to them small succulent tubers. The flowers are in axillary, multiflorous, pendulous racemes. The corolla is papilionaceous, of a pale pink color, with a purplish tinge. The legume when ripe is about seven inches long, and contains two or three seeds. It ripens at all seasons, but is most abundant during the rainy season from June to September. The seeds are the part used. The plant, which is indigenous to Western Africa, has been introduced into India and Brazil, and is said to flourish in the latter country. The market supplies are obtained from the regions surrounding the mouth of the Niger and the lower portion of the Calabar River, the chief port of export being Lagos (*Ap. Ztg.,* xxvi, p. 568; xxvii, p. 137). Only one other species (*P. mesoponticum* Taub.), also of tropical Africa, is known. For a paper on the botanical description, history, etc., of *Physostigma venenosum* by J. U. Lloyd, see *West. Drug.,* 1897, 249.

This bean was brought to the notice of the scientific public by Daniell, in 1846. Considerable attention was attached to the subject, and specimens of the bean were obtained by Christison from the Gold Coast. These were planted in the Botanical Garden at Edinburgh, and produced a perennial creeper. In the year 1859, specimens of the plant were sent from Calabar, which came under the observation of Balfour, of Edinburgh, who was thus enabled to ascertain its botanical character.

Properties.—The seeds are officially described as follows: "Oblong or ellipsoidal, somewhat compressed reniform, from 15 to 30 mm. in length and from 10 to 15 mm. in thickness;

externally reddish or chocolate brown, smooth, somewhat wrinkled near the brownish-black groove, the latter being about 2 mm. in width and extending almost the entire length of the convex edge and in which are found frequently the remains of the white membranous funiculus, the margins of the seed-coat on both sides of the groove somewhat elevated, of a yellowish-red or brownish-red color and somewhat thickened; embryos large, white, with short hypocotyl and two concavo-convex cotyledons; taste at first starchy, afterwards acrid. The powder is grayish-white, starch grains numerous, from 0.005 to 0.15 mm. in diameter, ellipsoidal or somewhat reniform, and usually with a distinct cleft and frequently with radiating or irregular fissures; fragments of seed-coat with very thick, reddish-brown cells, being either palisade-like or very irregular and resembling stone cells, but the walls are not lignified; an occasional fragment with tracheæ showing reticulate thickenings. Physostigma yields not more than 3 per cent. of ash." *U. S.*

Physostigmine was official in the Br. Pharm., 1885, and was thus described: "In colorless or pinkish crystals, slightly soluble in water, but readily soluble in alcohol and in diluted acids. The aqueous solution has an alkaline reaction, when warmed with or when shaken with dilute solution of potash becomes red, and when evaporated to dryness over a water bath leaves a bluish residue, the acidified solution of which is beautifully dichroic, being blue and red." *Br.*, 1885.

Assay.—"Introduce 15 Gm. of Physostigma in No. 60 powder, into a flask of about 250 mils capacity, and add 150 mils of ether. Stopper the flask, shake it well and allow it to stand ten minutes, then add 10 mils of an aqueous solution of sodium bicarbonate (1 in 20) and shake the mixture vigorously at intervals during four hours. Now add 15 mils of distilled water, again shake the flask well, and, when the drug has settled, decant 100 mils of the ether solution, representing 10 Gm. of Physostigma. Filter the solution through a pledget of purified cotton into a beaker and rinse the graduate and cotton with ether. Add 20 mils of tenth-normal sulphuric acid V.S. and evaporate off the ether, stirring during the evaporation with a rubber-tipped glass rod. After the resinous and fatty matter has agglutinated, pour off the acid solution through a wetted filter into a separator. Redissolve the residue in the beaker in about 15 mils of ether, add 2 mils of tenth-normal sulphuric acid V.S., evaporate off the ether with continued stirring as before and pour the acid solution on the filter. Repeat this operation until all the alkaloid is extracted and then wash the filter with distilled water until it is free from alkaloids. Collect the solution and washings in a separator, add sufficient sodium bicarbonate to make the solution decidedly alkaline to litmus and completely extract the alkaloids by shaking it out repeatedly with ether. Wash the combined ether solutions with 10 mils of distilled water, separate the water completely, and filter the ether solution, washing the container and filter with ether. Evaporate the ether solution to dryness, dissolve the alkaloids from the residue in exactly 5 mils of tenth-normal sulphuric acid V.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal T.S. as indicator.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 27.52 milligrammes of the alkaloids of Physostigma (see Part III, Proximate Assays, No. 15)." *U. S.*

Calabar beans are occasionally substituted by a number of more or less similar seeds of African plants. Hartwich (*S. W. P.*, 1905, p. 441) calls attention to a false physostigma found in the Hamburg drug market which is derived from *Pentaclethra macrophylla* Benth., a leguminous tree indigenous to tropical Africa. The seeds are dark reddish-brown, from 5 to 7 cm. long, about 5 cm. broad and about 1 cm. thick. They are flattened-oval or roundish-triangular.

Physostigma yields its virtues to alcohol, and imperfectly to water. The shell constitutes, according to Edwards, 30 per cent., the kernel 70 per cent., of the bean. Jobst and Hesse (*J. P. C.*, March, 1864, p. 277) first isolated an active principle, which they found exclusively in the cotyledons. They obtained it by exhausting an alcoholic extract of the seeds with water, adding magnesia to neutralization, which is indicated by the liquid becoming brown, then concentrating, and treating with ether. The ethereal solution was shaken with a little weak sulphuric acid. The liquid separated into two layers—the upper, ethereal, containing no alkaloid, and the lower, a solution of the sulphate in water. The latter was separated, treated with magnesia, and afterwards with ether, which yielded the alkaloid on evaporation. The substance thus obtained they proposed to name *physostigmine*. In 1865 Vée and Leven (*C. R. A. S.*, 60, 1194) obtained, by treating the seeds in nearly the same manner, an alkaloid to which they gave the name *eserine*, which formed colorless tabular crystals of a bitter taste, readily soluble in ether, alcohol, or chloroform, but sparingly in water. The crystals contain 1 molecule of water, which they lose at 100° C. (212° F.), and the anhydrous alkaloid then fuses at from 102° to 103° C. (215.6°–217.4° F.). Eserine is now generally accepted as identical with physostigmine. In 1867, Hesse (*Ann. Ch. Ph.*, 141, 82) obtained the same alkaloid in a still purer state, perfectly colorless and tasteless, fusing at 45° C. (113° F.), and decomposing at 100° C. (212° F.) with red coloration. He gives it the formula $C_{15}H_{21}O_2N_3$.

A peculiarity of the alkaloid is that an aqueous solution of it, or of one of its salts, exposed to the air in the presence of potassium or sodium hydroxides, or lime, becomes red, owing to the absorption of oxygen. The coloring

matter is taken up by chloroform. The color is not permanent, but gradually changes to yellow, green, or blue. This test will detect less than the hundred-thousandth part of the alkaloid. The same property is possessed by the alcoholic extract of the bean. This is the cause of the color changes taking place in solutions dispensed in ordinary glass bottles. The change may be retarded by previously rinsing out the bottle with diluted hydrochloric acid, and subsequently with distilled water, or it may be entirely prevented by coating the inner surface of the dispensing vial with paraffin.

Harnack and Witkowski (*A. E. P. P.*, v; also x) in 1876 obtained still another alkaloid, which they named *calabarine*. It is soluble in alcohol and water, nearly insoluble in ether, melts at 132° C. (269.6° F.), and differs in physiological character from physostigmine. It is now generally known under the name of *eseridine*. The formula $C_{15}H_{23}O_3N_3$ has been given to it by Eber (*Ph. Ztg.*, 1888, p. 611), which differs from that of physostigmine, it will be seen, by H_2O only, and it is stated that the one can be changed into the other by the action of dilute acids. It has properties like eserine but in a milder degree. *Eseramine*, $C_{16}H_{25}O_3N_4$, is another alkaloid of feeble activity which is present. It was announced by Ehrenberg in 1893 (*Verhand. d. Gesellsch. Deutsche Natur. u. Aertzte.*, 1893, ii, p. 102). There is much reason for believing that calabarine is a decomposition product derived from physostigmine. (Husemann, *A. E. P. P.*, 1878, 14; Harnack, *A. E. P. P.*, x.)

Still another alkaloid announced by Salway is *physorenine*, $C_{14}H_{18}O_3N_2$. It is a powerful myotic like eserine. It is believed to be an intermediate product in the decomposition of eserine by alkalies, which results in the formation of a new base called *eseroline*, $C_{13}H_{18}ON_2$. Another decomposition product of eserine is produced by an excess of ammonia and is called *eserine blue*, $C_{17}H_{23}O_2N_3$.

Hesse obtained also a neutral fatty body, *physosterin*, by exhausting the cotyledons with petroleum benzin. It is closely allied to cholesterin, but its chloroform solution is devoid of rotatory power. Its formula is $C_{26}H_{44}O + H_2O$, and its melting point is 133° C. (271.4° F.).

Uses.—The action of physostigma is practically that of its dominant alkaloid physostigmine, but the effects are more or less modified by the other alkaloids; thus calabarine is a stimulant to the spinal cord and in this regard antagonistic to physostigmine, while isophysostigmine possesses the physiological properties of the dominant alkaloid upon the unstriped muscle, but apparently not upon the other structures of the body. For this reason whenever the systemic action is desired the alkaloid should be given the preference over preparations of the whole drug. On the other hand, as a stimulant to the unstriped muscle of the intestines, as in *constipation*, the whole drug may properly be used.

Poisoning.—Calabar bean has been used from time immemorial by the natives of Africa as an ordeal, and, when given by their head men, usually proves fatal to the accused, unless free vomiting occurs. A draught containing 19 seeds pounded and infused in water is said to have killed a man in an hour. In the experiments of Fraser, it was found that the integuments of the seeds, as well as the shell, are distinctly purgative. It is probable that in the fresh bean they are also emetic, and that the priests or chiefs who administer the ordeal take advantage of this in regulating the effects of the poison to suit their own purposes; sometimes, however, even the pure alkaloid causes vomiting. (Gubler.) Of seventy children poisoned in Liverpool by eating Calabar beans which had been thrown upon a waste heap, vomiting occurred, or was produced by emetics, in all except one, in whom four kernels caused death. The nausea and vomiting came on in about half an hour, the nervous symptoms in less than an hour.

There are generally diminution of reflexes, coarse muscular tremors which may be sufficiently violent to suggest convulsions, contraction of the pupil, and progressive diminution of motor power. In the fatal cases death is generally due to paralytic asphyxia.

In the treatment of physostigma poisoning the stomach should be thoroughly washed out either with an emetic or the stomach pump, and tannic acid or compound solution of iodine given as a chemical antidote. Atropine, which is a partial physiological antagonist, should be given in doses of about one-fiftieth of a grain (0.0013 Gm.), and strychnine and other stimulants employed as indicated.

Dose, one to three grains (0.065–0.2 Gm.).

PHYSOSTIGMINÆ SALICYLAS. U. S.

PHYSOSTIGMINE SALICYLATE Physostig. Salicyl. [Eserine Salicylate]

(phȳ-sǫ-stĭg-mĭ'næ săl-ĭ-cȳ'lăs)

"The salicylate [$C_{15}H_{21}O_2N_3.C_7H_6O_3 = 413.25$] of an alkaloid obtained from physostigma. Preserve it in small, well-closed containers, protected from light." *U. S.*

Salicylate d'Esérine, *Fr. Cod.*; Physostigminum salicylicum, *P. G.*; Physostigminsalicylat, Eserinsalicylat, *G.*

Preparation.—This salt is preferred to the sulphate of the alkaloid (see page 852) on account of its greater stability. Its advantage is that it is not deliquescent. Birkenwald (*Ph. Z. R.*, 1891, 657) gives the following process: 100 parts of physostigmine sulphate are dissolved in a suitable quantity of water, and an excess of a solution of sodium bicarbonate added and agitated with several portions of absolute ether; the ethereal solutions

are filtered into a beaker containing 35.5 parts of salicylic acid dissolved in ether, thoroughly mixed, and the physostigmine salicylate collected upon a filter, washed with absolute ether and dried, protected from sunlight and air. Any excess of salicylic acid that may have been present is removed by the washing with ether. The success of this method depends upon rapid manipulation and preventing exposure to sunlight, otherwise the salt obtained will be of a red color due to the decomposition of physostigmine and formation of *rubeserine;* washing the crystals with alcohol will remove any red color, but with loss of physostigmine salicylate.

Properties.—It is officially described as "colorless or faintly yellowish, shining, acicular, or short columnar crystals; odorless. It acquires a red tint when long exposed to light and air. *Great caution must be used in tasting it.* One Gm. of Physostigmine Salicylate dissolves in 75 mils of water, 16 mils of alcohol, 6 mils of chloroform, and in 250 mils of ether at 25° C. (77° F.); also in 16 mils of water at 80° C. (176° F.) and in 5 mils of boiling alcohol. Its cold, saturated aqueous solution is neutral or at most only faintly acid to litmus. Upon standing twenty-four hours, this solution usually acquires a pink color. This color is produced rapidly by the addition of a few drops of sodium hydroxide T.S. Ferric chloride T.S. produces a deep violet color in an aqueous solution of Physostigmine Salicylate; a solution of chlorinated lime added to an aqueous solution of the salt produces a red color. Evaporate about 0.005 Gm. of the salt to dryness with a few drops of ammonia water; a blue residue is produced, which is soluble in alcohol, and, when so dissolved, yields a red fluorescent solution upon the addition of acetic acid in excess. No weighable ash remains on incinerating 0.1 Gm. of Physostigmine Salicylate. Precipitate the salicylic acid from 10 mils of a cold, saturated aqueous solution of the salt with a slight excess of hydrochloric acid and filter the mixture; the filtrate is not rendered turbid at once by the addition of a few drops of barium chloride T.S. (*sulphate*). A solution of about 0.1 Gm. of Physostigmine Salicylate in 2 mils of sulphuric acid does not become darker than yellow within five minutes (*readily carbonizable impurities*)." *U. S.*

Uses.—The physiological actions of physostigmine divide themselves into three groups: depression of the central nervous system, increased irritability of the autonomic nerves, and stimulation of unstriped muscles. The depression of the central nervous system is most noticeably manifested in the diminution of reflex activities from depression of the spinal cord. After toxic doses the drug also depresses the respiratory center. Its effects upon the autonomic nerves are antagonistic to those of atropine (see p. 206). Among the most important of these actions are the slowing of the pulse by stimulation of the vagus, and the contraction of the pupil by stimulation of the oculomotor nerve. In large doses it also increases secretion, although it is not employed practically for this purpose. Although in sufficient dose physostigmine causes a rise in blood pressure by its stimulating action upon the cardiac and vascular muscles, the only therapeutically important action upon muscle tissue is the intestinal tract. According to the studies of Magnus (*A. G. P.,* 1905, cviii, p. 1), it increases both the tone and the extent of contraction of the intestinal muscles.

Physostigmine is used in medicine chiefly to meet one of three indications. To contract the pupil in *glaucoma* and other diseases of the eye, it may be directly instilled into the diseased organ in strengths of from one-foruth to one-half of one per cent. As a stimulant to peristalsis it is useful in *chronic constipation, phantom tumor,* post-operative *intestinal atony, flatulent colic,* and other conditions of deficient activity of the alimentary muscles. As a sedative to the spinal cord it has been used in *tetanus* and *strychnine poisoning,* but clinical experience has shown that it is of much less value than chloral or the bromides. Recently it has been recommended by Kaufmann in the treatment of *tachycardia.* (*W. K. W.,* 1912, p. 1080.)

Dose, one-sixtieth to one twenty-fourth of a grain (0.0011–0.0025 Gm.).

PHYSOSTIGMINÆ SULPHAS. Br.

PHYSOSTIGMINE SULPHATE [Eserine Sulphate]

(phȳ-sǫ-stĭg-mĭ'næ sŭl'phās)

"Physostigmine Sulphate, $(C_{15}H_{21}N_3O_2)_2$, H_2SO_4, is the sulphate of an alkaloid, physostigmine, obtained from the seeds of Physostigma venenosum, *Balfour.*" *Br.*

Sulfate d'Eséŕine, *Fr. Cod.;* Physostigminum sulfuricum, *P. G.;* Physostigminsulfat, *G.;* Sulfatu de eserina, *Sp.*

This salt was not admitted to the U. S. P. IX, but is retained in the Br.; it is preferable to the salicylate on account of its greater solubility, but on exposure to the air it soon assumes an extractive consistence which renders it difficult to dispense; the salicylate is free from this objection.

Preparation.—*Physostigmine* or *eserine sulphate* is obtained by M. A. Petit in the following manner: A hydro-alcoholic extract of the bean is dissolved in four parts of distilled water, and the solution filtered. To the solution is added one gramme of potassium bicarbonate for every 20 grammes of extract, and the mixture is shaken with ether in excess. The ether, which takes up nearly all the alkaloid, is separated after standing for a few minutes. A little distilled water is then added, and afterwards sulphuric acid drop by drop, the liquid being shaken after each drop, and tested with litmus paper until exactly neutral. After standing, the aqueous solution is separated from the ether, which now contains none of the alkaloid. This ether is then employed as before, and the

operation repeated three or four times, so as completely to exhaust the original solution, and the liquid obtained each time is added to the last aqueous solution. This contains the physostigmine sulphate nearly pure. To purify this, it should be passed through the same process as the original solution of the extract. The resulting solution may be evaporated to crystallization if desired; but usually the evaporation is carried only so far as to get rid of all the ether present. If enough water be added to the solution to make as many grammes as there were drops of sulphuric acid (H_2SO_4) employed, each gramme will represent approximately one centigramme of the alkaloid.

Petit and Polonovski conducted experiments with the view of discovering salts of eserine which would be stable and non-hygroscopic; they made *eserine benzoate, eserine meta-cresotate, eserine citrate,* and *eserine tartrate.* Processes will be found in *J. P. C.,* 1894, 55.

Properties.—It is officially described as "minute white crystals, becoming yellowish on exposure to air and light; very deliquescent. Readily soluble in *water,* soluble in *alcohol* (90 per cent.). Aqueous solution neutral to *litmus;* yields the *reaction* characteristic of sulphates; yields with dilute *solution of sodium hydroxide* a white precipitate turning pink and forming a red solution with excess of the reagent; when mixed with *solution of ammonia* and evaporated to dryness on a water-bath it leaves a bluish residue, the solution of which in very dilute acids is dichroic, being red by reflected and blue by transmitted light. A minute fragment dissolved in a few drops of *fuming nitric acid* forms a yellow liquid, which, on warming on a water-bath, turns orange, then blood-red, and on evaporation to dryness leaves a green residue; this residue turns violet-blue on exposure to the fumes of *nitric acid,* and when moistened with the acid gives gradually a blood-red color, which changes to greenish-yellow on the addition of *water.* A dilute aqueous solution applied to the eye causes contraction of the pupil. No appreciable ash." *Br.*

Physostigmine sulphite has been patented and it is stated that it is more stable than either the salicylate or sulphate.

The medicinal properties, uses, and dose of physostigmine sulphate are the same as those of *Physostigminæ Salicylas.*

Dose, from one-sixtieth to one twenty-fourth of a grain (0.0011–0.0025 Gm.).

Off. Prep.—Lamellæ Physostigminæ, *Br.*

PICRORHIZA. Br.

PICRORHIZA

(pĭc-rō-rhī'zą)

"Picrorhiza is the dried rhizome of Picrorhiza Kurroa, *Royle.*" *Br.*

Kutki, Katki, Kuru, Kuruwa, Kaur, Karru, Kutaki, Kali-kutki, or Black Kutki, Katukurogani.

Picrorhiza Kurroa Royle (*P. Kurrooa* Benth.), more properly known as *P. Lindleyana* (Wall. Wettst.), is a low, hairy perennial herb (Fam. *Scrophulariaceæ*), indigenous to the Alpine Himalayas. The rootstalk or the rhizome has long been used in India and has been frequently spoken of by European and Mahometan writers as *black hellebore,* but is essentially different.

Properties.—*Picrorhiza* occurs "in cylindrical pieces two to five centimetres long, and four to eight millimetres thick, sometimes terminating in a stem or scaly leaf-bud; brittle. Cork greyish-brown, wrinkled, with transverse leaf scars and small buds. Fracture short. In transverse section internally dark and porous, with a thin, greyish cork and narrow ring of tangentially elongated wood-bundles. No odor; taste very bitter." *Br.*

Picrorhiza resembles externally the rhizome of *Gentiana Kurroo* Royle (Fam. *Gentianaceæ*), the latter, however, is uniformly brown internally, whereas the rhizome of Picrorhiza is darker or black, whence its name kali or black kutki. It is the dried rhizome of an Alpine-Himalayan plant, *Kurroa.* From this rhizome H. Warden has separated a glucoside, *picrorhizin,* which is freely soluble in water and alcohol and appears to be the bitter principle of the drug; also a red-brown, resinous, tasteless body, *picrorhizetin,* and, perhaps, cathartic acid (*Pharmacog. Indica,* vol. 3).

Uses.—The natives of India attribute active antiperiodic power to picrorhiza, which appears to be a powerful bitter tonic with slight laxative action. It is given in *doses* of from one to twenty grains (0.065–1.3 Gm.) as a tonic and from forty to fifty grains (2.6–3.2 Gm.) as an antiperiodic, usually in combination with aromatic.

Off. Prep.—Extractum Picrorhizæ Liquidum, *Br.;* Tinctura Picrorhizæ, *Br.*

PILOCARPINÆ HYDROCHLORIDUM. U. S.

PILOCARPINE HYDROCHLORIDE Pilocarpin. Hydrochl. [Pilocarpine Chloride, Pilocarpine Hydrochlorate, Pilocarpinæ Hydrochloras, U. S. 1890]

(pī-lo-căr-pī'næ hȳ-dro-ȼhlōr'ī-dŭm)

"The hydrochloride ($C_{11}H_{16}O_2N_2.HCl = 244.62$) of an alkaloid obtained from pilocarpus. Preserve it in well-closed containers, protected from light." *U. S.*

This alkaloidal salt is usually obtained by the process given under *Pilocarpus* for the alkaloid (see page 857).

Properties.—Pilocarpine hydrochloride is officially described as in "colorless, translucent crystals, odorless and having a faintly bitter taste; hygroscopic on exposure to the air. One Gm. of Pilocarpine Hydrochloride dissolves in 0.3 mil of water, 3 mils of alcohol, and in 366 mils of chloroform at 25° C. (77° F.); also in 1.5 mils of alcohol at 60° C. (140° F.); insoluble in ether. Its aqueous solution (1 in

20) is neutral or at most only slightly acid to litmus. When dried to constant weight at 100° C. (212° F.) it melts between 195° and 198° C. (383°–388.4° F.). Silver nitrate T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in nitric acid. Dissolve 0.01 to 0.02 Gm. of Pilocarpine Hydrochloride in 2 mils of distilled water in a test tube, add 2 mils of a slightly acid solution of hydrogen dioxide, and then cover the mixture with a small layer of benzene. Now add 3 or 4 drops of a solution of potassium dichromate (1 in 300) and shake the mixture gently; the benzene layer acquires a violet color, while the aqueous layer remains yellow (distinction from *other alkaloids*). (If more than 0.02 Gm. of the salt is used, the benzene turns blue, and the reaction is no longer characteristic.) No weighable ash remains on incinerating 0.1 Gm. of Pilocarpine Hydrochloride. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is colorless or at most only faintly yellow (*readily carbonizable impurities*). The addition of ammonia water or potassium dichromate T.S. to 10 mils of an aqueous solution of the salt (1 in 100) produces no turbidity (*various foreign alkaloids*)." *U. S.*

Uses.—Pilocarpine is the physiological antagonist of atropine, exciting those nerve endings which are paralyzed by that alkaloid. Thus it causes contraction of the pupil by stimulating the peripheral ends of the oculomotor nerve, increased flow of saliva by acting on the chorda tympani, slowing of the pulse through vagal stimulation (for some unknown reason the pulse rate is often increased in human beings), free sweating, and increased peristalsis of the intestines. The effects upon secretion are especially pronounced, the quantity of sweat brought out by a single dose of the alkaloid has been estimated at from 9 to 15 ounces. Ewing has shown that in the case of the salivary glands at least (*J. P. Ex. T.*, 1911, iii, p. 1) the increase is not merely in the watery constituents, but represents a true excitation of glandular activity because the solid matters and specific ferment of the secretion are also augmented. Usually there is more or less compensatory corollation between the degree of action on the various glandular structures, that is, if the sweat is greatly increased the effects upon the salivary glands, for instance, will be comparatively slight. There has been considerable difference of opinion among clinicians as to whether pilocarpine has any effect upon the kidney, and if so, what is the nature of this action, but the studies of Baco and Plumier (*J. de P. P.*, 1908, x, p. 32) have shown that the changes in the urinary output are secondary to the effects on the circulation; thus if the drug causes a fall of blood pressure the quantity of urine is diminished, but if there is no change in the circulation the kidney activity is unaffected. It is probable that in human beings the loss of water through the skin will also affect the quantity of urine.

Pilocarpine is used in medicine chiefly as a sudorific, either for the purpose of evacuating *dropsies* or aiding in the elimination of toxic substances, as in *uremia, gout, chronic rheumatism* and similar complaints. It should always, if possible, be used in conjunction with some form of external heat so as to determine the blood towards the skin. If used incautiously it may give rise to a very dangerous pulmonary edema. The mechanism of this is three-fold, an increase in the bronchial secretions, a reduction of the force of the circulation, and a spasm of the bronchial muscles. If the action of the drug has been directed towards the skin by other diaphoretic measures and the dose has not been unduly large, the likelihood of this accident is extremely remote. Its occurrence is the signal for the immediate exhibition of atropine. We believe that the doses sometimes employed are much larger than necessary. If properly used more than one-eighth of a grain hypodermically is very rarely needed. Pilocarpine has also been recommended by Reid (*J. A. M. A.*, 1911, lvi, p. 1739) in the treatment of *pruritus*. It is believed by some to have an effect upon the growth of the hair and is used both internally and topically in the treatment of *baldness*. Robinson (*J. A. M. A.*, 1914, lxiii, p. 63) reports favorable results in the treatment of *hypertension*. It is also asserted to be of value in *catarrhal jaundice*. As a local remedy it is employed by ophthalmologists as a myotic in strengths of one-half to one per cent.

Dose, one-twentieth to one-fourth of a grain (0.003–0.016 Gm.).

PILOCARPINÆ NITRAS. U. S., Br.

PILOCARPINE NITRATE Pilocarpin. Nit.

(pī-lo-cär-pī'næ nī'trăs)

"The nitrate [$C_{11}H_{16}O_2N_2.HNO_3 = 271.17$] of an alkaloid obtained from pilocarpus. Preserve it in well-closed containers, protected from light." *U. S.* "Pilocarpine Nitrate, $C_{11}H_{16}N_2O_2.HNO_3$, is the nitrate of an alkaloid, pilocarpine, obtained from the leaves of Pilocarpus microphyllus, *Stapf*, and other species of Pilocarpus." *Br.*

Preparation.—This salt may be made by adding pure pilocarpine to diluted nitric acid, carefully evaporating the solution, and purifying the crystals by solution in alcohol and recrystallizing.

Properties.—The official description is as follows: "Pilocarpine Nitrate occurs in shining crystals; odorless; permanent in the air. One Gm. of Pilocarpine Nitrate dissolves in 4 mils of water and in 75 mils of alcohol at 25° C. (77° F.); also in 21 mils of alcohol at 60° C. (140° F.); insoluble in chloroform or ether. It melts between 170° and 173° C. (338° and 343.4° F.). Carefully pour an aqueous solution of the salt, mixed with an equal volume of ferrous sulphate T.S., over sulphuric

acid without shaking; a brown ring appears at the juncture of the two layers. The addition of a few drops of silver nitrate T.S. to 5 mils of an aqueous solution of the salt (1 in 20), acidulated with nitric acid, produces not more than an opalescence (*chloride*). In other respects the salt responds to the tests for identity and purity under *Pilocarpinæ Hydrochloridum.*" *U. S.*

"A white crystalline powder. Soluble in 8 parts of *water.* Melting point about 176° C. (348.8° F.). Yields with *sulphuric acid* a colorless solution slowly becoming green on the addition of *potassium bichromate.* When a solution of 0.01 gramme in 5 millilitres of *water* is mixed with 2 drops of *diluted sulphuric acid* and then with 1 millilitre of *solution of hydrogen peroxide,* 1 millilitre of *benzene,* and 1 drop of *solution of potassium chromate,* and the mixture well shaken and allowed to separate, the benzene is colored bluish-violet. No appreciable ash." *Br.*

The medicinal properties and dose are the same as those of *Pilocarpinæ Hydrochloridum.*

Dose, from one-twentieth to one-fourth of a grain (0.003–0.016 Gm.).

PILOCARPUS. U. S.

PILOCARPUS Pilocarp. [Jaborandi]

(pī-lō-cär'pŭs)

"The dried leaflets of *Pilocarpus Jaborandi* Holmes, known in commerce as Pernambuco Jaborandi, or of *Pilocarpus microphyllus* Stapf, known in commerce as Maranham Jaborandi (Fam. *Rutaceæ*), without the presence or admixture of more than 5 per cent. of the stalks bearing the leaflets and stems of the same plant, or other matter, and yielding not less than 0.6 per cent. of the alkaloids of Pilocarpus." *U. S.*

Jaborandi Folia, *Br.* 1898; Jaborandi leaves, Pilocarpi Foliola; Jaborandi, *Fr. Cod.*; Folia Jaborandi, *P. G.*; Jaborandiblätter, *G.*; Jaborandi, *It.*; Jaborandi (Hoja de), *Sp.*

It is unfortunate in our opinion that this drug was omitted from the Br. Pharm., 1914; it was official in the Br. Pharm., 1898, under the title "Jaborandi Folia."

Pilocarpus was first introduced to the notice of the European profession by Coutinho (*J. P. C.,* 4e sér., xx, 51) under the name of Jaborandi, a name which has adhered to the drug, although the terms Jaborandi, Iaborandi and Jamborandi are used in South America to designate various pungent, sudorific plants, most of which belong to the genus Piper, but some of which have no botanical relation at all with the peppers. Although the leaves of the *Piper Jaborandi* have been sent into commerce as Jaborandi, none of the true jaborandis of South America have any physiological relations with the official drug, which in South America is known as *Arruda do Mato* or as *Arruda brava* or, rarely, as *Jamguarandi* or *Jaurandi.*

The genus Pilocarpus consists of woody shrubs belonging to the Rutaceæ and inhabits tropical and subtropical America, including Cuba, Guadeloupe, Martinique, and probably other islands. For elaborate botanical and histological studies of the commercial species of Pilocarpus, see the articles by A. Duvall, *B. Sc. Pharm.,* iii, pp. 41 and 98; Geiger, *Ber. d. D. Phar. Ges.,* 1897, p. 356; Hartwich, *Apoth. Zeit.,* 1900; Holmes *P. J.,* 1903, p. 713; and 1904, p. 54; Schneider, *Jour. of Pharmacology* (N. Y. C. P.), 1897, No. 6; Tunman, *S. W. P.,* xlvii, p. 177. The following species of the genus have been used in medicine:

P. Jaborandi Holmes (*P. officinalis* Poehl).—This plant inhabits the northern and northeastern part of Brazil whence its leaves find their way through Sergipe, Allogoa, Sobral and Ceará, etc., to Liverpool and Hamburg, the chief centers of European commerce in the drug. Like those of *P. selloanus* its leaves are two or three jugate and are especially separated from those of the *P. pennatifolius* by the fact that all of the leaflets except the terminal one have their bases cordate, while the bases of all the leaflets of *P. pennatifolius* are attenuate. This species is practically no longer obtainable in commerce, only occasional lots being imported.

P. pennatifolius Lemaire (*P. simplex* Baillon) inhabits the southern portion of Brazil and Paraguay, whence its leaves were formerly largely exported through Buenos Ayres and Rio Janeiro; at present they seem to have almost disappeared from commerce. The leaves are grayish-green in color, oval, elliptical, obtuse, attenuate at the summit, which is feebly emarginate, and also attenuate at their base but not petiolated. The species is recognized in the Belgian Pharmacopœia.

In the original specimens of jaborandi seen by Coutinho, and also in other specimens received from the doctor's family by F. V. Greene, U. S. N., some of the leaves are hairy, although most of them are smooth, and it seems probable that the species does contribute somewhat to the jaborandi of commerce.

P. selloanus Engler, formerly official in the U. S. P., appears to be a variety of *P. pennatifolius* Lemaire, from which it differs almost solely in the length of its flower stalk, which is six times as long as the flower bud, while that of *P. pennatifolius,* is but three to four times as long as the bud. *P. selloanus* seems to be the more southern plant of the two, and is especially abundant in Paraguay.

P. trachylophus Holmes.—The leaves of this species are smaller than those of the *P. Jaborandi,* and are oblong, elliptical, obtuse, and emarginate at the summit with cordate bases, symmetrically and shortly petiolate. The plant grows in Northeastern Brazil, especially in the provinces of Ceará and Maranhoa, and the leaves, although they contain so little of the alkaloid (about 0.2 per cent.) as to be of small value, have been sent into commerce in considerable quantities. Their color upon the surface is vivid green, below yellowish-green. The under surface is covered with short hairs.

P. microphyllus Stapf grows in the northeastern part of Brazil, whence the leaves, much mixed with the debris of the petioles, of the twigs and of the fruit, are sent to Liverpool and Hamburg. These leaves are alternate, imparipinnate having from one to five pairs of leaflets, or are often apparently simple owing to the failure of the lateral leaflets to develop. The leaflets are opposite, slightly pubescent, their petioles being marked by a deep longitudinal furrow. They vary very much in form, the base usually being attenuate and feebly cordate or unequal.

P. spicatus A. Saint-Hilaire (*P. parviflorus* Martius et Nees), inhabits the southern and northern portions of Brazil and can be recognized at once by its having simple leaves which are from 3 to 11 cm. long and from 1 to 4 cm. broad, and are tender or coriaceous and more or less pubescent and dotted. They are brownish-green above, paler beneath, and attached by a short twisted petiole. They appeared in commerce in 1895 under the name of *Arocati jaborandi. P. subcoriaceus* Engler is probably a variety of this species. *P. racemosus* Vahl, a native of Martinique, Cuba, Guadeloupe and probably other of the West Indian Islands, appeared first in commerce in 1903 as a new variety of jaborandi under the name of *Guadeloupe jaborandi.* The leaves are proportionately broader than those of *Pernambuco jaborandi,* more obovate in outline, of a purer green color, and are trifoliate or apparently simple. Considerable diversity of result has been obtained by chemists in the examination of the Guadeloupe jaborandi. Rocher (*A. J. P.,* 1900) obtained 1 per cent. of total alkaloids of which 0.6 per cent. was believed to be pilocarpine, the remainder jaborine. In the laboratory of Wright, Layman and Umney, only 0.34 per cent. of total alkaloids were reported as existing, while in an assay by A. J. Cownley (*P. J.,* 1903, lxxii) 0.6 per cent. of total alkaloids was obtained, about 50 per cent. of which was believed to be isopilocarpine. The commercial cultivation of jaborandi may some day be successful, as the *P. pennatifolius* has been found to grow freely in Sicily and produce a leaf containing a fair proportion of alkaloid. Pilocarpus is usually bought by assay. The variation in the percentage of alkaloid, according to the observations of A. Duval, depends not merely on the original contents of the drug but upon the fact that the alkaloid disappears when the pilocarpus is kept for some length of time in a moist atmosphere. Pilocarpus was at one time adulterated with spurious jaborandis, other foreign leaves, stems, dirt and mouldy leaves. At the present time the commercial article is of good quality. There are, however, reports of the leaves of other plants being substituted. Weigel states that under the name of *"Feuilles de Bois d'inde,"* the leaves of the logwood plant were substituted for Paraguay jaborandi. The most common adulterant appears to be in lots of *P. microphyllus,* which often contain leaves of the leguminous plant, *Tunatea decipiens* (Holmes), O. Kze. (*Swartzia decipiens* Holmes). In general appearance the two leaves resemble one another, both being imparipinnate and having the leaflets about the same size and shape, but in *P. microphyllus* the leaflets are opposite and the petioles are only slightly pubescent, while in the *Tunatea* the leaflets are alternate, and the petioles very pubescent. Then again, the absence of secreting hairs, the deep green of the upper and lighter green of the lower surface of the leguminous leaf serve easily to distinguish it from the true drug.

The following description of the drug is adapted from that of F. V. Greene, U. S. N., who had unquestionable specimens of the original jaborandi of Coutinho. The package contained several stems branched at an angle of about 20°, these branches being furnished with alternate leaves, which are imparipinnate, with from two to five opposite leaflets (Planchon has met with leaves having as many as seven or nine, and, more rarely, eleven leaflets) articulated to the rachis by short petiolules, thickened at the base. The leaflets, which are coriaceous in texture, vary considerably in size and outline. As a rule, they may be considered as oblong-lanceolate, and are entire, emarginate, with an unequal base. The midrib rises very little above the upper surface of the leaflet, but is very prominent and sharp on the lower. The veins, which are rather more prominent on the lower surface, leave the midrib at an angle of about 60°, pursue a parallel course across the leaflet, and finally turn up and anastomose within about a quarter of an inch of the margin. The leaflets are pellucidly punctate; the dots are the receptacles of secretion, are numerously and irregularly distributed over the whole surface, and are plainly visible when the leaflet is held up to the light. According to Conroy, the leaflets yield 0.76 per cent., the leafstalks only 0.37 per cent. of alkaloid. The fruit consists of five carpels, of which not more than two or three are usually developed to maturity; when ripe, the carpels dehisce into two valves, and then remind one strongly of miniature cockle shells with the valves open exposing the animals. The black, shining, reniform seeds (one for each carpel) have a lancet-shaped hilum, a sharp ridge on the back near the apex, and a smooth, pale yellow endocarp surrounding it.

Paraguay jaborandi from *P. pennatifolius* and *P. selloanus* is an inferior variety of the drug, which reaches European commerce from Buenos Ayres and from Rio Janeiro, and is believed to be collected in Paraguay. The leaves are thinner than those of the Pernambuco jaborandi, and have only two or three, never four, pairs of leaflets. It is also noticeable in the Paraguay variety that the lateral veins are not prominent, that the base is so tapered that the widest portion is above the middle, and that the upper surface is grayish-green.

Properties.—The Pernambuco and Maranham jaborandis are official, being described as follows:

"**Pernambuco Jaborandi.**—Leaflets when entire, oval, oblong, or elliptical, from 4 to 10.5 cm. in length and from 2 to 4 cm. in breadth and with short, stout petiolules; summits more or less rounded or acute and emarginate; bases rounded or acute and mostly unequal; margins entire and narrowly revolute; very smooth, shiny, coriaceous and glandular-punctate; upper surfaces grayish to brownish-green, midribs mostly depressed, under surfaces yellowish- or greenish-brown and slightly pubescent on the prominent midvein; peculiarly aromatic when crushed; taste bitterish, becoming somewhat pungent and having a sialogogue effect.

"**Maranham Jaborandi.**—Leaflets rhomboidally oval to obovate or elliptical from 1.5 to 5 cm. in length and from 1 to 3 cm. in breadth, the lateral ones nearly sessile, the terminal ones on margined petiolules, from 0.5 to 1.5 cm. in length; of a nearly uniform grayish or yellowish-green color, rather thin but otherwise resembling Pernambuco Jaborandi.

"Under the microscope, transverse sections of Pilocarpus show the upper epidermal cells with a yellowish layer of cutin from 0.005 to 0.01 mm. in thickness; palisade cells, 1 to 3 rows deep, being filled with chloroplastids; among the palisade cells occur large, nearly circular, oil-secretion reservoirs from 0.08 to 0.15 mm. in diameter; the dorsal pneumatic layer, from 10 to 20 rows in depth, the cells occasionally containing rosette aggregates of calcium oxalate from 0.01 to 0.025 mm. in diameter; distributed in the center of the leaf are the collateral fibro-vascular bundles each surrounded by a more or less interrupted circle of several rows of thick-walled, slightly lignified bast-fibers, tracheæ associated with strongly lignified wood-fibers; among the cells of the lower epidermis occur numerous stomata. On surface view the stomata are broadly elliptical, from 0.025 to 0.04 mm. in length, being uniformly smaller in Maranham Jaborandi. Upon both surfaces of Pernambuco Jaborandi occur a number of non-glandular, one-celled hairs, more or less bent or curved, from 0.08 to 0.5 mm. in length, thick-walled and with numerous, slight, centrifugal projections.

The powder is dark green or greenish-brown; epidermal cells on surface view 5- or 6-sided; stomata broadly elliptical, from 0.02 to 0.04 mm. in length, usually with four neighboring cells; fragments of fibro-vascular bundles showing tracheæ with simple or bordered pores or spiral thickenings, associated with thick-walled and strongly lignified wood-fibers; bast-fibers few, walls thick and only slightly lignified; calcium oxalate in rosette aggregates, from 0.01 to 0.025 mm. in diameter; fragments of laminæ showing large, oil-secretion reservoirs and usually containing one or more globules of oil; non-glandular hairs having thick walls, usually more or less broken, are occasionally found. Pilocarpus yields not more than 7 per cent. of ash." *U. S.*

An alkaloid was isolated in 1875 from jaborandi almost simultaneously by A. W. Gerrard and M. Hardy. To this the name of *pilocarpine* was given. Gerrard at the same time stated that there were at least two alkaloids in the leaves, and this view seemed to be confirmed when *jaborine* was discovered. He also obtained a volatile oil, tannic acid, a peculiar volatile acid, and potassium chloride. *Pilocarpine* may be prepared as follows. The leaves are exhausted with 80 per cent. alcohol containing 8 grammes of hydrochloric acid in a liter, the tincture is distilled and evaporated to the consistence of a liquid extract, and this is mixed with a small quantity of water, and filtered. The filtrate is treated with a slight excess of ammonia, and then with a large quantity of chloroform. The chloroform solution is agitated with water, to which hydrochloric acid is added, drop by drop, in sufficient quantity to neutralize the alkaloid, the hydrochloride of which is obtained in long needles on evaporating the aqueous solution, while foreign principles remain dissolved in the chloroform. By dissolving the crystals in water, treating the solution with ammonia and chloroform, and evaporating the latter solution, pilocarpine is obtained as a soft viscous mass, which is only slightly soluble in water, but is freely soluble in alcohol, ether, and chloroform.

Kingzett originally assigned pilocarpine the formula $C_{23}H_{34}O_4N_4 + 4H_2O$. Harnack and Meyer, on the other hand, give it as $C_{11}H_{16}O_2N_2$. The latter has been accepted, and is recognized by the U. S. Pharmacopœia. It was later definitely established as correct by the synthesis of pilocarpine afterwards effected by Hardy and Calmels. (*C. R. A. S.*, cv, pp. 68 to 71; also *A. J. P.*, 1887, p. 632.) By the action of hydrochloric acid or of barium hydroxide, pilocarpine, $C_{11}H_{16}O_2N_2$, is changed into *pilocarpidine*, $C_{10}H_{14}O_2N_2$, by the loss of a methyl group. Now Hardy and Calmels have converted β-pyridine-α-lactic acid, into *pilocarpidine*, the methyliodide of which by oxidation is converted into pilocarpine. The synthetical pilocarpidine and pilocarpine yield gummy derivatives similar to those obtained by Harnack and Meyer from the natural products. The physiological action of synthetical pilocarpine is identical with that af the natural alkaloid. Knudsen, E. Merck, and Petit and Polonovski all dispute the conclusions of Hardy and Calmels, and state that they failed to get pilocarpine by the synthetic method of these investigators. (*Proc. A. Ph. A.*, 1897, 716.) Petit and Polonovski (*J. P. C.* (6), v, 481) obtained *pilocarpic* and *pilocarpidic acids* from pilocarpine and pilocarpidine. Harnack and Meyer first stated that *jaborine* is easily formed from pilocarpine, and may be produced by simply heating the latter alkaloid. They also showed

that *pilocarpine* has physiological effects analogous to those of *nicotine*, while *jaborine* resembles *atropine* in its effects. Hardy and Calmels (*J. Chem. S.*, Sept., 1886, 815) state that pure, dry pilocarpine does not yield *jaborine* when heated at 100° C. (212° F.) for six hours, neither can this substance be obtained by the action of alcoholic iodide upon argentopilocarpidine. If, however, carefully dried pilocarpine be heated rapidly to 175° C. (347° F.), kept at this temperature for about half an hour, and the product extracted with water, made alkaline with baryta and shaken with ether, the ether will contain jaborine, the aqueous solution will contain pilocarpidine, $C_{10}H_{14}O_2N_2$, and *jaboric acid*. *Jaborine* separates from alcohol or ether in a brown mass, which changes to a brittle resinous solid. Its composition is considered to be $C_{22}H_{32}O_4N_4$; it has exactly twice the molecular formula of pilocarpine. It is insoluble in water, but dissolves readily in ether, and is soluble in jaboric acid. *Jaboric acid*, $C_{19}H_{25}N_3O_5$, is separated from pilocarpidine by precipitating with excess of silver nitrate, which forms a curdy precipitate of the composition $C_{19}H_{24}N_3O_5,AgNO_3$. Jaboric acid resembles jaborine in appearance, but is very soluble in water, and is not removed from its aqueous solution by ether. Pilocarpine contains besides the alkaloids, some resin, tannin, and a small amount of a terpene containing volatile oil. Pilocarpine combines with acids, and a number of the salts are to be had in commerce. The action of heat or alkalies decomposes pilocarpine into *isopilocarpine*, which upon oxidation yields pilocarpic acid, $C_{11}H_{16}N_2O_5$. The nitrate has probably been used most frequently, and it and the hydrochloride are now official. Gerrard tested the solubilities of several of the salts as follows. The nitrate is soluble in water, sparingly in cold but freely in boiling alcohol; it is insoluble in chloroform, benzene, carbon disulphide, and ether. The *phosphate* is soluble in water, sparingly in cold, more freely in boiling alcohol, from which on cooling it crystallizes in lustrous tables; it is insoluble in ether, chloroform, benzene, and carbon disulphide. The *hydrochloride* is freely soluble in water, alcohol and chloroform; insoluble in ether, benzene, and carbon disulphide. The *acetate* is soluble in water, alcohol, chloroform, benzene, and ether; insoluble in carbon disulphide. The *hydrobromide* is soluble in water, alcohol, and chloroform; insoluble in ether and carbon disulphide.

According to the researches of E. Harnack, *pilocarpidine* acts upon the animal organism in the same way as pilocarpine, but is somewhat less powerful.

An essential oil of sp. gr. 0.875, and boiling between 180° and 290° C. (356° and 554° F.), has been obtained by Schimmel & Co., in Leipsic. (*Ber. d. Chem. Ges.*, April, 1888.) The portions going over above 260° C. (500° F.) solidified on cooling, and yielded a solid hydrocarbon, which fuses at 27° to 28° C. (80.6°–82.4° F.). As it decolorizes notable amounts of bromine when in solution in petroleum benzin, it probably belongs to the olefine series. The yield of oil in pilocarpus is about 0.4 per cent. In a later report (Oct., 1893) they give as a probable constituent of the lower boiling portions of the oil, *dipentene*, $C_{10}H_{16}$. The total amount of essential oil varies, according to the freshness of the plant, from 0.2 to 1.1 per cent.

Assay.—"Introduce 15 Gm. of Pilocarpus in No. 60 powder into a 250 mil flask, add 150 mils of chloroform and proceed as directed under *Belladonnæ Radix*, page 222, fifth line of the assay, beginning with the word "Stopper," and decreasing the amount of water to be added after maceration to 5 mils. The 100 mils of chloroform solution must be drawn off from the bottom of the flask, and dissolve the alkaloids from the residue in 8 mils of tenth-normal sulphuric acid V.S.

"Each mil of tenth-normal sulphuric acid V.S. corresponds to 20.8 milligrammes of the alkaloids of Pilocarpus." *U. S.*

Uses.—The therapeutic virtues of jaborandi appear to be due entirely to the alkaloid pilocarpine and the crude drug is very rarely employed. For the consideration of its physiological and therapeutic properties, see page 854.

When an overdose of jaborandi, or its principle alkaloid, has been taken, the symptoms begin with flushing of the face and neck, soon followed by free sweating and salivation, both of which may be extremely profuse. Frequently there is nausea and sometimes vomiting, the pulse is usually somewhat more rapid than normal, the pupils contracted, and often there is *diarrhea*. In patients with circulatory disturbances, pulmonary edema may occur, and prove rapidly fatal. The antagonism between pilocarpine and atropine is about as complete as between any two drugs, and the most certain treatment for cases of poisoning by jaborandi, after evacuating the stomach, is the prompt administration of a full dose of atropine, or some substance containing it.

Dose, of jaborandi, from twenty to forty grains (1.3–2.6 Gm.).

Off. Prep.—Fluidextractum Pilocarpi, *U. S.*

PILULÆ.

PILLS

(pĭl'ù-læ)

Pilules, *Fr.*; Pillen, *G.*; Pillole, *It.*; Píldoras, *Sp.*

These are globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and which do not require to be given in large doses. Deliquescent substances should not be made into pills, and those which are efflorescent should be previously deprived of their water by crystallization. Care should be taken not to combine materials the mutual re-

action of which may result in a change of physical conditions.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins, and the addition of a little water to the former, and of a few drops of alcohol to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as wheat flour, starch, and powdered gum arabic, or with crumb of bread. Powders must be mixed with soft, solid bodies, as extracts, confections, soap, etc., or with tenacious liquids, as syrup, molasses, honey, mucilage or glycerin and the last-mentioned substance has been especially recommended in connection with a little alcohol. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used, but pills made with it are apt when kept to become hard and of difficult solubility in the liquids of the stomach, and if metallic substances are mixed with it the mass does not work well. A mixture of syrup and powdered gum arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Honey evaporated to about half its bulk has been highly recommended. Confection of rose and glucose are among the best excipients, when the pills are to be kept long. For the same purpose of keeping the pills soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended, but glycerin is still better. Glycerin incorporated with one-twenty-fifth of its weight of powdered tragacanth is said to cause pills to remain soluble for almost any length of time. The official mucilage of tragacanth is an excellent excipient. Martindale prepares a mass by heating together with constant stirring to 115.5° C. (240° F.) five parts by weight of glycerin and one of flour, or, when a very firm mass is required, equal parts of flour and glycerin. It has been objected that pills made with glycerin could not be handsomely gilded or silvered, the luster of the metal disappearing. This is true, however, only of very recent pills, or of those in which an excess of glycerin has been used. Many powders require only water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with the liquid. Care should always be taken that the substance added is not incompatible with the main constituents of the pill.

The materials should be accurately mixed together, and beaten in a mortar until formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric fluids. As pills frequently become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in waxed paper, putting it in covered pots, and occasionally moistening it as it becomes dry, or, more effectually, by keeping it in glass or well glazed jars, accurately closed with rubber cloth. The mass is made into pills by rolling it with a spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or, more accurately, by a machine. (See Remington's *Practice of Pharmacy,* 5th edition, p. 1217.) The pills receive a spherical form by being rolled between the fingers or by the use of one of the pill rolling machines. Mialhe describes a little instrument for rolling pills, composed of two circular plates, one about 12 inches, the other 6, in diameter, the former having a ledge at the border one-third of an inch high, the latter with a similar ledge, varying, according to the size of the pills, from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate, holding the divided portions of the pill mass. Similar pill rollers made of wood are now in use. In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose magnesium carbonate, rice flour, or starch may be used. Magnesium carbonate is sometimes incompatible with one of the ingredients of the pills, and licorice root is then preferable, though it occasionally becomes mouldy with very damp pills. The powder of lycopodium, which has been long in use in Europe, is now considerably employed in this country, and is perhaps one of the best substances for the purpose. It is the custom in some sections of the United States, particularly on the Pacific coast, to give the pill a coating of gold or silver leaf. This is done by agitating the pills, prepared without dusting powder, and with their surface still damp, or coated with a very small quantity of mucilage, with gold or silver leaf, in a hollow spherical wooden box made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle.

It was proposed by Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odor and counteracting deliquescence or chemical change from exposure to the air, but it sometimes interferes with their solubility in the stomach. This method of coating is largely used at the present time. One of the best machines that have been devised for gelatin coating pills extemporaneously on the small scale is that of H. Maynard, of Chicago. This consists of a circular plate in which are affixed twenty fine

needles; the pills are rolled into depressions, and are easily impaled on the points of the needles; they are then dipped into a solution of gelatin, gently rotated, and allowed to cool. Another plan, less effectual, but more convenient, is to introduce the pills into a spherical box, to drop on them enough syrup simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees either powdered French chalk, elm bark, or some similar substance, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be rendered agreeable to the taste and smell by aromatic additions, if deemed advisable. Calloud found that a good powder for coating pills, because little disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient water until a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. The same writer has since suggested, as still more effective, a powder made by forming a mucilage with one part of tragacanth and two parts of water, pressing this through linen, mixing it with twenty parts of sugar of milk, spreading the paste thus made in thin layers to dry, and then powdering. The pills may be simply moistened with water and then shaken in the powder. L'Hermite proposed first to agitate the pills in a mortar with a little concentrated solution of gum, and afterwards to put them into a box containing dry and very finely powdered sugar, to which a rotary motion is given. If the coating be not sufficiently thick, the process may be repeated. (*J. P. C.*, xxv, 460.) For a list of excipients for pills by J. Cohn, see *Proc. A. Ph. A.*, 1900, 469 from *Ph. Ztg.*, 1900, 221; also G. Grugge, *A. Ph. A. Year Book*, 1914, p. 81.

Gelatin coating on the larger scale is accomplished by the use of the vacuum apparatus of J. B. Russell (see Remington's *Practice of Pharmacy*), or by simply rotating the pills in contact with a solution of gelatin in large spherical vessels, such as are used for sugar coating.

The sugar coating of pills is now conducted upon a large scale by manufacturers, who send immense quantities both of popular and of official pills into the market thus protected. The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling and moved quickly backward and forward with an eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface, and afterwards very finely powdered and very dry white sugar is sifted or thrown over them, the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating made compact and smooth by the attrition. The process is aided by a gentle heat, but the heat must be guarded, lest the pills be much softened, and thus lose their shape and even discolor the coating. Dexterous manipulation is necessary in order that the process may succeed thoroughly. For practical remarks on the sugar coating of pills, see an essay by H. C. Archibald in *A. J. P.*, 1867, p. 199, and by Wm. R. Warner, Jr., and T. S. Wiegand in *A. J. P.*, 1902, 32. On a larger scale a pill coater of copper of peculiar construction, heated by steam pipes, is now used.

Still another method of coating pills, proposed by E. K. Durden, is to cover the pills with collodion, which completely conceals the taste. The solution employed by Durden had the sp. gr. 0.810, and two dippings gave a sufficient coating. (*A. J. P.*, xxi, 183.) It is, however, yet to be determined whether a coating of collodion would yield readily to the solvent powers of the gastric juice. Blanchard covers pills with a solution of Tolu balsam in ether, but H. C. Baildon objects to this, that it takes too long to dry, and suggests as a substitute a solution of a drachm of the balsam in three drachms of chloroform, which dries sufficiently in twenty minutes. If old and solid Tolu balsam be selected, it will be less liable to the objection of drying slowly. This balsam is officially employed in coating the U. S. pills of ferrous iodide. A solution of mastic in ether has also been used for coating pills, and the white of egg has been recommended for the same purpose.

Pills are sometimes coated with substances which do not dissolve in the stomach, with the object of permitting the passage of the undissolved pill into the intestines; for this purpose keratin coating has been largely used. (See *Keratin*, Part II, and Remington's *Practice of Pharmacy*, sixth edition.) *Salol* has also been employed, by melting it in an enamelled pan at a temperature of about 50° C. (122° F.) and dropping in the pills, rotating until covered, and then transferring to a dry pan, still rotating (to prevent adhesion) until cold. For further details, see *Pilulæ*, N. F. IV (Part III); *D. C.*, 1894, 123; *Ph. Ztg.*, xxxviii, 527.

An improved method of salol coating for pills intended for enteric use has been contributed by J. C. and B. L. DeG. Peacock (*Proc. P. Ph. A.*, 1915, p. 258). The particular points to be observed are the amount of salol to be used and the shape and size of the vessel used in melting the salol.

W. G. Toplis (*Proc. P. Ph. A.*, 1915, p. 262) proposes stearic acid as an enteric coating for pills and gives details of the method to be followed in producing a satisfactory article.

Pills which are to be kept long should be well dried, and put into bottles with loosely fitting stoppers to prevent mouldiness. Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills,

yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft. The British Pharmacopœia furnishes formulas for pill masses, using the title of "Pilula" instead of "Massa," the title of the class adopted by the U. S. Pharmacopœia; there is, in our opinion, a decided advantage in selecting a name for the class which is not likely to be confused with that used for the divided pills.

Pills containing silver nitrate, potassium permanganate or other easily oxidizable substances, should be made by diluting with kaolin or talc and massing with petrolatum or mixtures of petrolatum and paraffin. All organic matter should be excluded.

Compressed pills are made directly from the medicinal substance without the aid of an excipient. The drug, if not already in granular powder, is made so, and then forced into pill shape by means of a powerful press. For certain substances which are crystalline in structure, such as quinine bisulphate, potassium bromide, and potassium iodide, and which have some cohesiveness and yet are of easy solubility, the process is a good one. An apparatus was contrived by J. P. Remington for compressing pills (see 16th ed., *U. S. D.*, and *Practice of Pharmacy*, 5th ed., page 1233). It is made of cast steel; the base has two countersunk depressions with a short post in the center of each, and a lenticular depression is made in the upper surface of each post. A steel cylinder having a central aperture of the diameter of the post is placed in the depression, the proper quantity of powder is introduced, and the plunger, which has a corresponding lenticular depression on its lower surface, is placed on the powder and is struck a quick blow with a mallet; the powder is compressed, and the pill adheres to the cylinder; by removing the cylinder and holding it over a box and tapping the plunger again lightly, the pill is forced out and falls into a box.

Compressed tablets are now used to an enormous extent, being made by various manufacturers with machinery of ingenious construction; the fact of their requiring no excipient, the ease with which they can be tested, and their permanent character (in most cases being just as valuable years after they were made as when fresh) have caused their extensive employment. Care should be taken, however, not to use them in those few cases where very prompt action is required, as the powerful compression to which they are subjected renders them less quickly effective than the same drug administered in the form of a loose powder.

For a description of some of the more important forms of pill compressing machines with illustrations, see Remington's *Practice of Pharmacy*, sixth edition.

PILULÆ ALOES. U. S. (Br.)

PILLS OF ALOES Pil. Aloes

(pĭl'ŭ-læ ăl'ō-ēs)

Pilula Aloes, *Br.*; Aloes Pill; Pill of Barbados Aloes, Pill of Socotrine Aloes; Pilules d'Aloés et de Savon, *Fr. Cod.*; Pilules Aloétiques Savoneuses, *Fr.*; Aloepillen, *G.*

* "Aloes, in fine powder, *thirteen grammes* [or 201 grains]; Soap, in fine powder, *thirteen grammes* [or 201 grains]; Water, *a sufficient quantity*, to make *one hundred pills*. Mix the powders intimately, then incorporate sufficient water to form a mass, and divide it into *one hundred pills*." *U. S.*

"Aloes, in powder, 58 *grammes;* Hard Soap, in powder, 29 *grammes;* Oil of Caraway, 3 *millilitres;* Syrup of Glucose, 10 *grammes* or *a sufficient quantity*. Mix to form a mass." *Br.*

In the Br. Pharm., 1898, confection of rose was used as the excipient. It is now replaced by syrup of glucose.

The former British process for *Pill of Socotrine Aloes* was the same except that Socotrine was substituted for Barbados Aloes, and the volatile Oil of Nutmeg for Oil of Caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation and diminish its liability to irritate the rectum. Five of the U. S. pills, containing ten grains (0.65 Gm.) of aloes, may be given with a view to their purgative effect, but the preparation is usually employed as a laxative in *habitual costiveness*.

Dose, one, two or three pills at bedtime. The British pill mass is of very nearly the same strength as that of the U. S. Pharmacopœia.

PILULA ALOES ET ASAFETIDÆ. Br.

PILL OF ALOES AND ASAFETIDA

(pĭl'ŭ-lą ăl'ō-ēş ĕt ăs-ą-fĕt'ĭ-dæ)

Pilulæ Aloes et Asafœtidæ, *N. F.*; Pilules d'Aloés et d'Asefétide, *Fr.*; Aloe und Asfœtida-Pillen, *G.*

A process for these pills was not retained in the U. S. P. IX, but are recognized by the N. F. IV (see Part III); the British process is as follows:

"Aloes, in powder, 30 *grammes;* Asafetida, 30 *grammes;* Hard Soap, in powder, 30 *grammes;* Syrup of Glucose, 10 *grammes*, or *a sufficient quantity*. Mix to form a mass." *Br.*

In the Br. Pharm., 1898, confection of rose was used as the excipient. It is now replaced by syrup of glucose.

Pills made from this mass are peculiarly adapted, by the stimulant and carminative properties of the asafetida, to cases of *costiveness* attended with flatulence and debility of the digestive organs.

Dose, about four grains (0.26 Gm.) of the mass.

PILULA ALOES ET FERRI. Br.

PILL OF ALOES AND IRON

(pĭl'ŭ-lą ăl'o-ēş ĕt fĕr'rī)

Pilulæ Aloes et Ferri, *N. F.;* Pilulæ Italicæ Nigræ; Pilules d'Aloés et de Fer, *Fr.;* Pilulæ Aloeticæ ferratæ, *P. G.;* Eisenhaltige Aloepillen, Aloe und Eisenpillen, Italienische Pillen, *G.*

"Exsiccated Ferrous Sulphate, 10 *grammes;* Aloes, in powder, 20 *grammes;* Compound Powder of Cinnamon, 35 *grammes;* Syrup of Glucose, 35 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

These pills were deleted from the U. S. P. IX, but were introduced without change into the N. F. IV (see Part III).

This pill differs from the preparation of the same name in the British Pharmacopœia in the substitution of aromatic powder for the compound powder of cinnamon. It is essentially an old preparation of the Edinburgh Pharmacopœia, was omitted in the original British, and re-introduced and continued in the present edition. The Br. Pharm., 1898, improved this mass by substituting exsiccated ferrous sulphate for the crystallized salt formerly employed, and by the use of syrup of glucose instead of confection of rose. It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with ferrous sulphate. This pill is especially adapted to *amenorrhea* with debility of the stomach and constipation.

Dose, of the Br. mass, from three to eight grains (0.2–0.5 Gm.); of the N. F. pills, from one to three pills.

PILULA ALOES ET MYRRHÆ. Br.

PILL OF ALOES AND MYRRH

(pĭl'ŭ-lą ăl'o-ēş ĕt mŷr'rhæ)

Pilulæ Aloes et Myrrhæ, *N. F.;* Rufus's Pills; Pilule d'Aloés et de Myrrhe, Pilules de Rufus, *Fr.;* Rufussche Pillen, *G.*

"Aloes, in powder, 44 *grammes;* Myrrh, in powder, 22 *grammes;* Syrup of Glucose, 34 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

These pills were deleted from the U. S. P. IX, but were introduced without change into the N. F. IV (see Part III).

This composition has been long in use, under the name of *Rufus's Pills.* It is employed, as a warm stimulant cathartic, in *general debility* attended with *constipation,* and in *retention* or *suppression of the menses.*

Dose, of the Br. mass, from four to eight grains (0.26–0.5 Gm.); of the N. F. pills, three to six pills.

PILULÆ ASAFŒTIDÆ. U. S.

PILLS OF ASAFETIDA Pil. Asafœt.

(pīl'ŭ-læ ăs-ą-fœt'ĭ-dæ)

Pilules d'Asefétide, *Fr.;* Asafœtida-Pillen, *G.*

* "Asafetida, *twenty grammes* [or 309 grains]; Soap, in fine powder, *six grammes* [or 93 grains]; Water, *a sufficient quantity,* to make *one hundred pills.* Beat the solids together with water, so as to form a mass, and divide it into *one hundred pills.*" *U. S.*

Each of these pills contains three grains (0.20 Gm.) of asafetida. They are a convenient form for administering asafetida, the unpleasant odor and taste of which render it very offensive in the liquid state.

Dose, one to three pills.

PILULÆ CATHARTICÆ COMPOSITÆ. U. S.

COMPOUND CATHARTIC PILLS Pil. Cathart. Co.

(pīl'ŭ-læ cą-thär'tĭ-cæ cŏm-pŏş'ĭ-tæ)

Antibilious Pills; Pilules cathartiques composées, *Fr.;* Abführpillen, *G.*

* "Compound Extract of Colocynth, *eighty grammes* [or 2 ounces av., 360 grains]; Mild Mercurous Chloride, *sixty grammes* [or 2 ounces av., 51 grains]; Resin of Jalap, in fine powder, *twenty grammes* [or 309 grains]; Gamboge, in fine powder, *fifteen grammes* [or 231 grains]; Diluted Alcohol, *a sufficient quantity,* to make *one thousand pills.* Mix the powders intimately, then incorporate a sufficient quantity of diluted alcohol to form a mass, and divide it into *one thousand pills.*" *U. S.*

This cathartic compound was first made official in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action and a peculiar tendency to the biliary organs. Such an official preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel, and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. It is highly important that these pills be prepared in exact compliance with the directions, and that the *compound extract of colocynth* and the *resin of jalap* used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the resin, or to the use of a compound extract of colocynth made with nearly inert scam-

mony, inferior aloes, and insufficient colocynth, and altogether badly prepared.

Each pill weighs about 3 grains (0.194 Gm.), and contains 2.70 grains (0.175 Gm.) of active ingredients. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required, but is particularly applicable to the early stages of *bilious fevers*, to *hepatitis*, *jaundice*, and all those derangements which depend on congestion of the portal circle. It should not be used in habitual constipation.

Dose, one to three pills.

PILULA COLOCYNTHIDIS COMPOSITA. Br.

COMPOUND PILL OF COLOCYNTH

(pĭl'ŭ-lą cŏl-o-cўn'thį-dĭs cọm-pŏș'į-tą)

Pilulæ Colocynthidis Compositæ, *N. F.*; Cochia Pills; Pilules de Coloquinte composées, *Fr. Cod.*; Pilules cochées mineures, *Fr.*; Zusammengesetzte Koloquinten-Pillen, *G.*

"Colocynth Pulp, in powder, 20 *grammes;* Aloes, in powder, 35 *grammes;* Scammony Resin, in powder, 35 *grammes;* Potassium Sulphate, in powder, 5 *grammes;* Oil of Cloves, 5 *millilitres;* Distilled Water, *a sufficient quantity*. Triturate the Oil of Cloves with the Potassium Sulphate; add the Colocynth Pulp; mix; add the Aloes and Scammony Resin; mix; add Distilled Water, and mix to form a mass." *Br.*

This is not, like the old London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials—one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. Potassium sulphate is used to promote the more complete division of the aloes and scammony. The preparation is actively cathartic. This pill is also official in the N. F. IV (see Part III).

Dose, from five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Pilula Colocynthidis et Hyoscyami, *Br.*

PILULA COLOCYNTHIDIS ET HYOSCYAMI. Br.

PILL OF COLOCYNTH AND HYOSCYAMUS

(pĭl'ŭ-lą cŏl-o-cўn'thį-dĭs ĕt hў-ọs-cў'ą-mī)

Pilulæ Colocynthidis et Hyoscyami, *N. F.*; Pilules de Coloquinte et d'Extrait de Jusquiame, *Fr.*; Koloquinten-Bilsenkrautpillenmasse, *G.*

"Compound Pill of Colocynth, 50 *grammes;* Extract of Hyoscyamus, 25 *grammes;* Distilled Water, *a sufficient quantity*. Mix to form a mass." *Br.*

This was an official pill of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power.

Dose, from five to twenty grains (0.32–1.3 Gm.).

This pill is also official in the N. F. IV (see Part III).

PILULÆ FERRI CARBONATIS. U. S. (Br.)

PILLS OF FERROUS CARBONATE Pil. Ferr. Carb. [Ferruginous Pills, Chalybeate Pills, Blaud's Pills]

(pĭl'ŭ-læ fĕr'rī cär-bọ-nā'tĭs)

"Each Pill contains not less than 0.06 Gm. of $FeCO_3$." *U. S.*

Pilula Ferri, *Br.*; Iron Pill; Pilules Ferrugineuses de Blaud, *Fr. Cod.*; Pilules Chalybées de Blaud, *Fr.*; Pilulæ Ferri carbonici Blaudii, *P. G.*; Blaudsche Pillen, *G.*; Pillole di carbonato ferroso, *It.*; Pildoras de Blaud, *Sp.*

* "Granulated Ferrous Sulphate, *sixteen grammes* [or 247 grains]; Potassium Carbonate, *eight grammes* [or 123.5 grains]; Sugar, *four grammes* [or 62 grains]; Tragacanth, in fine powder, *one gramme* [or 15.5 grains]; Althæa, in fine powder, *one gramme* [or 15.5 grains]; Glycerin, Water, each, *a sufficient quantity*, to make *one hundred pills*. Rub the potassium carbonate, in a mortar, with a sufficient quantity (about *five drops* each) of glycerin and water, then add the ferrous sulphate and sugar, previously triturated together to a uniform, fine, powder, and rub the mass thoroughly, until it assumes a greenish color. When the reaction is complete, incorporate the tragacanth and althæa, and, if necessary, add a little more water, so as to obtain a mass of pilular consistence. Divide this into *one hundred pills*.

"Note.—In this process the 8 Gm. of potassium carbonate may be replaced by 7.2 Gm. of monohydrated sodium carbonate." *U. S.*

"Exsiccated Ferrous Sulphate, in powder, 33 *grammes;* Exsiccated Sodium Carbonate, in powder, 21 *grammes;* Tragacanth, in powder, 2 *grammes;* Gum Acacia, in powder, 8 *grammes;* Glucose, 31 *grammes;* Distilled Water, 2 *millilitres*. Mix the Glucose, Distilled Water, and Exsiccated Ferrous Sulphate; add the Exsiccated Sodium Carbonate; mix and set aside for ten minutes, or until the reaction is complete; add the Tragacanth and Gum Acacia, and mix to form a mass. This Pill contains about 22.5 per cent. of ferrous carbonate." *Br.*

Assay.—"Dissolve three Pills in 15 mils of diluted sulphuric acid and dilute the solution with distilled water to about 100 mils. The immediate titration with tenth-normal potassium dichromate V.S., potassium ferricyanide T.S. being used as indicator, shows not less than 0.06 Gm. of $FeCO_3$ in each pill.

"Each mil of tenth-normal potassium dichromate V.S. used corresponds to 0.011584 Gm. of $FeCO_3$. Each Pill of Ferrous Carbonate corresponds to 5.2 mils of tenth-normal potassium dichromate V.S." *U. S.*

In the U. S. P., 1890, the name of this pill was changed to *Pilulæ Ferri Carbonatis* and the *Pilulæ Ferri Compositæ* of the U. S. P., 1880, was dropped, which sometimes led to a complication; the U. S. P., 1890, has since been retained, as it would lead to confusion to change the name again. It should be remembered, however, that "pills of ferrous carbonate" no longer means pills made from Vallet's Mass but Blaud's pills.

These pills afford one of the best forms of exhibiting iron, in the treatment of *anemia,* being nearly free from astringency. As their peculiar advantages depend upon the presence of ferrous carbonate, which speedily changes into the ferric salt on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. They are sometimes called *Griffith's pills.* They closely resemble *Blaud's ferruginous pills,* made originally in 1831, and celebrated in France as a remedy in *chlorosis,* prepared from equal weights of ferrous sulphate and potassium carbonate, made into a pilular mass. (See *P. J.,* 1894, 131.) The pills contain, as the result of double decomposition, ferrous carbonate and potassium sulphate. Van de Velde and Van Melckebeke prefer the sodium bicarbonate to the potassium salt. For a brief historical account of these pills, see a paper by John Humphrey in *P. J.,* 1903, 643.

Blaud's pills may become very hard upon standing, but if properly made, they undergo very little alteration. For an assay of a very old specimen, see *N. J. Ph. A.,* 1912, p. 73.

Dose, from two to six pills, to be taken three times a day; of the Br. mass, five to twenty grains (0.32–1.3 Gm.).

PILULÆ FERRI IODIDI. U. S.

PILLS OF FERROUS IODIDE Pil. Ferr. Iod.

(pĭl'ŭ-læ fĕr'rī ī-ŏd'ĭ-dī)

Pilules d'Iodure ferreux, *Fr. Cod.;* Pilules de Blancard, *Fr.;* Eisenjodürpillen, *G.;* Pillole di protojoduro di ferro, *It.;* Píldoras de yoduro ferroso, *Sp.*

* "Reduced Iron, *four grammes* [or 62 grains]; Iodine, *five grammes* [or 77 grains]; Glycyrrhiza, in fine powder, *four grammes* [or 62 grains]; Sugar, in fine powder, *four grammes* [or 62 grains]; Extract of Glycyrrhiza, in fine powder, *one gramme* [or 15.5 grains]; Acacia, in fine powder, *one gramme* [or 15.5 grains]; Water, Balsam of Tolu, Ether, each, *a sufficient quantity,* to make *one hundred pills.* Add *six mils* [or 97 minims] of water to the reduced iron, contained in a small mortar, and then, gradually add the iodine, stirring constantly until the liquid ceases to have a reddish tint. Then add the remaining powders, previously well triturated together, and mix the whole thoroughly. Transfer the mass to a porcelain dish, evaporate the excess of moisture on a water bath, with constant stirring, and when the mass has acquired a pilular consistence divide it into *one hundred pills.* Dissolve *ten grammes* [or 154 grains] of balsam of tolu in *fifteen mils* [or 243 minims] of ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle. Pills of Ferrous Iodide are free from the odor of iodine. Triturate a few of the pills with water, and filter the liquid; the filtrate does not assume more than a light blue tint upon the addition of starch T.S. (absence of more than traces of *free iodine*)." *U. S.*

This process does not differ essentially from that formerly official.

The pills of ferrous iodide were introduced into the U. S. Pharmacopœia at the revision of 1850. The present official pills are formed on the plan proposed by Procter, in imitation of *Blancard's pills* (*A. J. P.,* May, 1860), and are much superior to those made by the U. S. process of 1850, or by that of the British Pharm., 1885. Magnes-Lahens especially recommended the following formula: "Take of pure Iodine, 4.10 grammes; Powdered Iron, 1.90 grammes; Powdered Sugar, 2.50 grammes; Powdered Gum Arabic, 2.50 grammes; Distilled Water, 2.50 grammes. Put in an iron dish the Water and the powdered Iron, add the Iodine gradually, and facilitate the reaction by stirring with a spatula of iron and by warming a little; when the reaction is complete, add the Gum and the Sugar, then heat to about 50° C. (122° F.), stirring until the mass ceases to drop when a little is taken up on the spatula. If necessary, five grammes of powdered licorice root may be incorporated into the mass, which is then to be rolled into one hundred pills." (*A. J. P.,* 1873, p. 498.) The iodine and iron unite directly to form ferrous iodide in solution, which is protected against the oxidizing influence of the air by the sugar and excess of reduced iron, while the licorice and gum serve to give due consistence and plasticity to the pilular mass. The pills are still further protected from the air by the impervious coating of balsam of Tolu, which readily yields to the softening and solvent properties of the gastric liquids. The great disadvantage of the pill of ferrous iodide, as ordinarily prepared, is that it will not keep—crumbling by time and exposure, and evolving iodine in consequence of the oxidation of the iron. The preparation, made according to the U. S. formula has stood the test of time, and we have seen pills which, four years after their preparation, exhibited no signs of change. Each pill contains about a grain (0.065 Gm.) of ferrous iodide and two-fifths of a grain (0.024 Gm.) of reduced iron. The therapeutic uses of this preparation are the same as those of ferrous iodide. (See *Ferri Iodidum.*)

Dose, one to three pills.

PILULA HYDRARGYRI SUBCHLORIDI COMPOSITA. Br.

COMPOUND PILL OF MERCUROUS CHLORIDE [Compound Calomel Pill, Plummer's Pill]

(pĭl'ū-lą hȳ-drär'gy̨-rī sub-ċhlō'rį-dī cǫm-pŏs'į-tą)

Pilulæ Antimonii Compositæ, *N. F.;* Compound Pills of Antimony; Pilula Calomelanos Composita, *Br.* 1864; Compound Pill of Mercurous Chloride; Pilules alterantes composées, Pilules antidartreuses, Pilules de Plummer, *Fr.;* Plummersche Pillen, Zusammengesetzte Calomelpillen, *G.*

"Mercurous Chloride, 20 *grammes;* Sulphurated Antimony, 20 *grammes;* Guaiacum Resin, in powder, 40 *grammes;* Gum Acacia, in powder, 1 *gramme;* Tragacanth, in powder, 1 *gramme;* Syrup of Glucose, 10 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

Compound pills of antimony were dropped in the U. S. P. VIII, but the National Formulary IV has introduced the compound pill of antimony of the U. S. P., 1890, without alteration (see Part III). This pill is official in the British Pharmacopœia, 1914, castor oil, which was used as an excipient, being replaced by syrup of glucose.

We prefer the title "Compound Calomel Pill" of the former British Pharmacopœia, as not liable to any mistake, and as most expressive of the quality of the medicine. The antimonial employed, though under a different name, is identical with the old U. S. precipitated sulphide. According to Vogel a reaction takes place between the calomel and the sulphurated antimony, resulting in the production of antimony chloride and mercury sulphide. The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's Pills.* The combination is well adapted to the treatment of *chronic rheumatism* and of scaly and other *eruptive diseases of the skin,* especially when accompanied with a syphilitic taint.

Dose, four to eight grains (0.26–0.5 Gm.) or more, morning and evening.

PILULA IPECACUANHÆ CUM SCILLA. Br.

PILL OF IPECACUANHA WITH SQUILL

(pĭl'ū-lą ĭp-ę-căc-ū-ăn'hæ cŭm sçĭl'lą)

Pilules d'Ipécacuanha et de Scille, *Fr.;* Brechwurzel-Meerzwiebelpillen, *G.*

"Compound Powder of Ipecacuanha, 30 *grammes;* Squill, in powder, 10 *grammes;* Ammoniacum, in powder, 10 *grammes;* Syrup of Glucose, *a sufficient quantity.* Mix to form a mass. This Pill contains about 5 per cent. of Opium." *Br.*

This is an old-fashioned combination of expectorants, intended for *chronic bronchitis,* but scarcely in keeping with modern practice.

Dose, from five to ten grains (0.32-0.65 Gm.).

PILULA IPECACUANHÆ CUM URGINEA. Br.

PILL OF IPECACUANHA WITH URGINEA

(pĭl'ū-lą ĭp-ę-căc-ū-ăn'hæ cŭm ŭr-gĭn'ē-ą)

"Compound Powder of Ipecacuanha, 30 *grammes;* Urginea, in powder, 10 *grammes;* Ammoniacum, in powder, 10 *grammes;* Syrup of Glucose, *a sufficient quantity.* Mix to form a mass. This Pill contains about 5 per cent. of Opium." *Br.*

This is the same as Pill of Ipecacuanhæ with Squill, except that Indian Squill or Urginea is used in place of the Mediterranean variety.

PILULÆ PHOSPHORI. U. S. (Br.)

PILLS OF PHOSPHORUS Pil. Phosphor.

(pĭl'ū-læ phŏs'phǫ-rī)

Pilula Phosphori, *Br.;* Phosphorus Pill; Pilules au Phosphore, Pilules Phosphorées, *Fr.;* Phosphorpillen, *G.*

* "Phosphorus, *six-hundredths of a gramme* [or 0.93 grains]; Althæa, in No. 60 powder, *six grammes* [or 93 grains]; Acacia, in fine powder, *three grammes* [or 46 grains]; Chloroform, Glycerin, Water, Balsam of Tolu, Ether, each *a sufficient quantity,* to make *one hundred pills.* Dissolve the phosphorus, in a test-tube, in *five mils* [or 81 minims] of chloroform, with the aid of a very gentle heat, replacing from time to time any of the chloroform which may be lost by evaporation. Mix the althæa and acacia in a mortar, next add the solution of phosphorus, then immediately afterwards a sufficient quantity (about *four mils* [or 65 minims]) of a mixture of *two volumes* of glycerin and *one volume* of water, and quickly form a mass; divide it into *one hundred pills.* Dissolve *ten grammes* [or 154 grains] of balsam of tolu in *fifteen mils* [or 243 minims] of ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle." *U. S.*

"Phosphorus, 1 *gramme;* Oil of Theobroma, 40 *grammes;* Wool Fat, 11 *grammes;* Kaolin, 16 *grammes;* Sodium Sulphate, dried at 100° C. (212° F.), 32 *grammes;* Carbon Disulphide, 20 *millilitres.* Dissolve the Phosphorus and 20 *grammes* of the Oil of Theobroma in the Carbon Disulphide. Allow the solution to evaporate in a mortar until a pasty mass is obtained. To this add the remainder of the Oil of Theobroma together with the other ingredients, and mix to form a mass. This Pill contains 1 per cent. of Phosphorus. It is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. It should be freshly prepared." *Br.*

The increasing use of phosphorus in the free state made the introduction of phosphorus pills a necessity. The problem of preventing the oxidation of the phosphorus is believed to be

solved by dissolving it in an excess of warm chloroform; this is accomplished in a stoppered test-tube, for it has been shown that no oxidation takes place in the presence of chloroform vapor. It is necessary to form the mass quickly, so that the chloroform may not all evaporate and leave the phosphorus exposed to the action of the air. Chloroform is preferable to carbon disulphide, as recommended in the Br., for, although the latter is a better solvent, it is difficult to rid the mass of the disgusting odor. (See *A. J. P.*, 1875, 253, 501; 1878, 584; and *N. R.*, 1876, 189, 332; 1877, 32; *D. C.*, 1883, 180; *P. J.*, 1883, 923.)

The formula for this pill in the British Pharmacopœia, 1914, has been improved and simplified by replacing white wax and lard with oil of theobroma and wool fat, and its strength has been reduced to one-half of that of the Br., 1898.

Each official U. S. pill contains about 1-100th of a grain (0.0006 Gm.) of phosphorus.

Dose, of the U. S. pills, one pill three times a day; of the Br. mass, one grain (0.065 Gm.).

PILULA PLUMBI CUM OPIO. Br.

PILL OF LEAD WITH OPIUM

(pĭl'ū-lą plŭm'bī cŭm ō'pĭ-ō)

Pilulæ Opii et Plumbi, *N. F.;* Pilules d'Acétate de Polmb et d'Opium, *Fr.;* Bleiacetat-Opiumpillenmasse, *G.*

"Lead Acetate, in powder, 80 *grammes;* Opium, in powder, 12 *grammes;* Syrup of Glucose, 8 *grammes,* or *a sufficient quantity.* Mix to form a mass. This Pill contains about 12 per cent. of Opium." *Br.*

This pill would be better left to extemporaneous prescription, the requisite proportion of opium to the acetate varying in different cases. It is also official in the N. F. IV (see Part III).

Dose, two or three grains (0.13–0.20 Gm.) to begin with.

PILULA QUININÆ SULPHATIS. Br.

PILL OF QUININE SULPHATE

(pĭl'ū-lą quĭ-nī'næ sŭl-phā'tĭs)

Pilule de Quinine Sulfate, *Fr.;* Chininpillenmasse, *G.;* Píldoras de sulfato quinico, *Sp.*

"Quinine Sulphate, 82 *grammes;* Tartaric Acid, in powder, 3 *grammes;* Glycerin, 12 *grammes;* Tragacanth in powder 3 *grammes.* Triturate the Quinine Sulphate with the Tartaric Acid; add the product to the previously mixed Glycerin and Tragacanth; mix to form a mass." *Br.*

The reason for introducing a quinine pill mass in the British Pharm. is doubtless to serve the convenience of dispensers and to save time; tartaric acid aids in solubility and in making the pills smaller, while glycerin keeps the mass from undue hardening.

Dose, two to eight grains (0.13–0.5 Gm.).

PILULÆ RHEI COMPOSITÆ. U. S. (Br.)

COMPOUND PILLS OF RHUBARB Pil. Rhei Co.

(pĭl'ū-læ rhē-ī cŏm-pŏs'ĭ-tæ)

Pilula Rhei Composita, *Br.;* Pilules de Rhubarbe composées, *Fr.;* Rhabarber und Aloepillen, *G.*

* "Rhubarb, in No. 80 powder, *thirteen grammes* [or 201 grains]; Aloes, in fine powder, *ten grammes* [or 154 grains]; Myrrh, in fine powder, *six grammes* [or 93 grains]; Oil of Peppermint, *five-tenths of a mil* [or 8 minims]; Water, *a sufficient quantity,* to make *one hundred pills.* Mix the oil of peppermint intimately with the powders, then incorporate sufficient water to form a mass; divide it into *one hundred pills.*" *U. S.*

"Rhubarb, in powder, 25 *grammes;* Aloes, in powder, 20 *grammes;* Myrrh, in powder, 14 *grammes;* Hard Soap, in powder, 14 *grammes;* Oil of Peppermint, 2 *millilitres;* Syrup of Glucose, 25 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

This is a tonic laxative, useful in *costiveness.* If made in quantity the pills should be kept in loosely stoppered bottles. The use of glycerin favors the formation of mouldiness through the attraction of moisture, and it was replaced in the formula of the Br. Ph., 1898, by syrup of glucose.

Dose, of the compound rhubarb pills, two to four pills, or from five to fifteen grains (0.32–1.0 Gm.) of the mass, twice a day.

PILULA SAPONIS COMPOSITA. Br.

COMPOUND PILL OF SOAP

(pĭl'ū-lą są-pō'nĭs cŏm-pŏs'ĭ-tą)

Pilulæ Opii, *U. S. VIII,* Pill of Opium; Pilules de Savon composées, *Fr.;* Seifenpillenmasse, *G.*

"Opium, in powder, 20 *grammes;* Hard Soap, in powder, 60 *grammes;* Syrup of Glucose, 20 *grammes,* or *a sufficient quantity.* Mix to form a mass. This Pill contains about 20 per cent. of Opium." *Br.*

This pill is practically identical with the opium pill of the U. S. VIII. There is no evident need of such a pill; it might much more wisely be left to extemporaneous prescription. The name was probably intended to conceal the nature of the preparation, but, in our opinion, it is a mistake to omit the only important ingredient from the title. One grain (0.065 Gm.) of opium is contained in five grains (0.32 Gm.) of the mass.

Dose, from two to five grains (0.13–0.32 Gm.).

PILULA SCILLÆ COMPOSITA. Br.

COMPOUND SQUILL PILL

(pĭl'ū-lą sçĭl'læ cŏm-pŏs'ĭ-tą)

Pilules de Scille composées, *Fr.;* Meerzwiebelpillenmasse, *G.*

"Squill, in powder, 25 *grammes;* Ginger, in powder, 20 *grammes;* Ammoniacum in powder, 20 *grammes;* Hard Soap, in powder, 15 *grammes;* Syrup of Glucose, 20 *grammes,* or

a sufficient quantity. Mix to form a mass." *Br.*

This preparation was dropped at the 1880 revision of the U. S. Pharmacopœia.

This is a stimulating expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of *chronic bronchitis.* The mass should be freshly made when wanted, as the squill which it contains is liable to be injured by keeping.

Dose, from five to ten grains (0.32–0.65 Gm.).

PILULA URGINEÆ COMPOSITA. Br.

COMPOUND URGINEA PILL

(pĭl'ŭ-lą ŭr-gĭn'ē-æ cǫm-pŏs'ĭ-tą)

"Urginea, in powder, 25 *grammes;* Ginger, in powder, 20 *grammes;* Ammoniacum, in powder, 20 *grammes;* Hard Soap, in powder, 15 grammes; Syrup of Glucose, 20 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

This pill is the same as the Compound Squill pill, except that the Indian Squill, Urginea, replaces the ordinary variety.

Dose, from five to ten grains (0.32–0.65 Gm.).

PIPER. U. S.

PEPPER [Black Pepper]

(pī'pẹr)

"The dried, unripe fruit of *Piper nigrum* Linné (Fam. *Piperaceæ*), without the presence or admixture of more than 2 per cent. of stems or other foreign matter." *U. S.*

Piper Nigrum, *Br.* 1898; Common Pepper; Poivre noir, *Fr. Cod.;* Poivre, *Fr.;* Schwarzer Pfeffer, *G.;* Pepenero, *It.;* Pimienti negra, *Sp.;* Fifil uswud, *Arab.;* Lada, *Malay;* Maricha, *Jav.;* Sahan, *Palembang.*

The pepper vine (*Piper nigrum*) is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark green color, and attached by strong sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are red when ripe.

The plant grows wild in Cochin-China and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, Japan, and many other places in the East; also to some extent in the West Indies. The best pepper is affirmed to be produced in Malabar, but Europe and America derive their chief supplies from Sumatra and Java. The plant is propagated by cuttings, and is supported by props, or trees planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The plant sometimes begins to bear as early as the first year after planting, increases in its yield to the fifth or sixth year, when it produces eight or ten pounds, and begins to lose its productiveness about the fifteenth year. The berries are gathered as soon as one is seen to turn red—*i.e.,* before they are all perfectly ripe—and upon being dried, become black and wrinkled. The greatest production is in Sumatra, and the ports of export are principally Singapore and Penang, the Malabar pepper coming from Tellicherry. In England, at least, it is customary to mix peppers of different origin in grinding, taking Malabar for weight, Penang for strength, and Sumatra for color. (*Bulletin U. S. Dept. of Agric.,* No. 13, 1887.) The importations from the Strait Settlements to the United States of unground black and white pepper is on an average about 20,000,000 pounds annually. Owing to the widespread cultivation of pepper a large number of varieties exist; these receive their names from the place of their production or their ports of shipment, as Singapore, Acheen, Penang, Siam, Tellicherry, Trang, Lampong, etc. For a description of the most important of these varieties with the percentage of active constituents contained in each, see J. W. Gladhill, *A. J. P.,* Feb., 1904; Kraemer and Sindall, *A. J. P.,* 1908, p. 1; also Blyth, *Foods: Their Composition and Analysis.*

White pepper is the ripe berry, deprived of a part of its pericarp by maceration in water and subsequent friction, and afterwards dried in the sun. It occurs as yellowish more or less broken grains with a smooth shiny surface from which the epicarp or outer layer of the fruit has been removed. It is sold in the market either as a whole white pepper or as broken white pepper; the whole peppers are very likely to have some of the epicarp or hull remaining. The removed hull is sold separately under the name of "pepper hulls;" it forms a light to dark brown powder, with a very pungent odor and taste and contains large amounts of the oleoresin of pepper, but according to Gladhill, no piperine. The hulls are sometimes sold mixed with broken white pepper. This mixture contains more oleoresin and less piperine than does the pure pepper; the percentage of the two active constituents varying according to the percentage of drugs in the mixture. White pepper is much less pungent but more aromatic than black pepper.

Long Pepper is obtained from *Piper officinarum* DC., and *P. longum* L., the former species yielding the principal commercial supplies and being grown in Java, India, and the Philippines. The plants are distinguished in having their flowers in dense, short, terminal, and nearly cylindrical spikes and their fruits, consisting of very small one-seeded berries or drupes, embedded in a pulpy matter. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant, and dried

in the sun. The fruit of the *P. officinarum* is cylindrical, 2 to 6 cm. long and 4 to 7 mm. in diameter, indented on its surafce, of a dark-gray color, a weak aromatic odor, and a pungent fiery taste. The fruits of *P. longum* are shorter and thicker. Dulong found its chemical composition to be closely analogous to that of black pepper. Like that, it contains *piperine,* a concrete oil or soft resin upon which its burning acridity depends, and a volatile oil to which it probably owes its odor. Its medicinal virtues are essentially the same as those of black pepper, but it is inferior to that spice, and is seldom used except as an adulterant. *West African* or *Ashantee Pepper* is the fruit of *P. Clussii,* C. DC., which grows abundantly in tropical Africa. It does not come into Western commerce, although much used in Africa. The berry is described as resembling cubeb, but less rugose, and with a more slender pedicel, and having the odor and taste of black pepper. Stenhouse found piperine in this variety of pepper.

Kissi Pepper is a fruit yielded by the *Piper Famechoni,* Heckel, of Upper Guinea. The berries, which grow in cylindrical clusters, are small, blackish-brown, ovoidal, with a cubeb-like pedicel at their base. Their powder is very aromatic, with an especially pleasant taste. They have been found by A. Barille to contain 4.5 per cent. of volatile oil and 3.7 per cent. of piperine. (*J. P. C.,* 1903, 106.)

Properties.—The dried berries are "nearly globular, from 3.5 to 6 mm. in diameter, epicarp very thin, easily separable from the sarcocarp; externally blackish-brown or grayish-black, coarsely reticulate; unilocular, 1-seeded; seed nearly white, hollow, adhering to the pericarp; odor aromatic, slightly empyreumatic; taste aromatic and very pungent. The powder is a mixture of blackish-brown fragments of the pericarp and nearly white fragments of the endosperm and embryo; starch grains spherical or somewhat angular, from 0.001 to 0.003 mm. in diameter, mostly in the polygonal cells of the endosperm; stone cells of the epicarp varying from nearly isodiametric or palisade-like to long tapering or somewhat irregular in shape, with thick porous walls and large lumina frequently containing a reddish-brown pigment; stone cells of the endocarp unevenly thickened, the outer walls being usually rather thin, and the lumina usually filled with a reddish-brown substance; oil cells with suberized walls and containing a yellowish oil, from which monoclinic prisms of piperine occasionally separate. Pepper yields not less than 6 per cent. of non-volatile extract, soluble in ether (see Part III, Test No. 13). It contains not less than 25 per cent. of starch. Pepper yields not more than 7 per cent. of ash. The amount of ash in Pepper, insoluble in diluted hydrochloric acid, does not exceed 2 per cent. of the weight of Pepper taken." *U. S.*

For information on the pharmacognosy of pepper, see Winton and Moeller in the "*Microscopy of Vegetable Foods;*" Winton and Bailey, *Ztchr. f. Unters. d. Nahr. u. Genussm.,* 1905, ix, p. 227; Spaeth, *Ibid.,* 1908, xv, p. 472; Kraemer and Sindall, *A. J. P.,* 1908, lxxx, p. 1; Collin in *Ann. des. Falsifications,* 1910, iii, p. 272.

They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar principle called *piperine* (see Part II), an acrid concrete oil or soft resin of a green color, a balsamic volatile oil, isomeric with oil of turpentine, a colored gummy substance, an extractive matter, like that found in leguminous plants capable of being precipitated by infusion of galls, starch, a portion of bassorin, tartaric and malic acids, lignin, and various salts. William Johnston (König's *Nahrungs- und Genussmittel,* 3d ed., Bd. i, 1046) finds that *piperidine,* $C_5H_{11}N$, is an invariable constituent of pepper in amounts varying from 0.21 to 0.77 per cent.

Piperidine is of great chemical interest as being a simple derivative of pyridine, which seems to underly the molecular structure of so many alkaloids. Piperidine is a hexalhydropyridine and can easily be obtained from pyridine by the action of tin and hydrochloric acid. Conversely piperidine can be changed into pyridine when sulphuric acid at 300° C. (572° F.) or gentle oxidizing agents act upon it. Coniine, it will be remembered, is a normal propylpyridine. Moore and Row (*J. P.,* 1898) have shown that piperidine resembles coniine in its physiological effects.

Heliotropin. (*Piperonal.*)—This interesting substance, although used almost exclusively in perfumery, has been recommended by Fraggani (*Ph. Centralh.,* xxviii, 253) as an antiseptic and antipyretic. It may be obtained by the oxidation of piperic acid. This piperonal is the aldehyde of piperonylic acid, $C_6H_3(CO\,OH)\begin{matrix}O\\O\end{matrix}>CH_2$, which, as the formula indicates, is the methylene ester of protocatechuic acid, $C_6H_3COOH(OH)_2$. See also *Schim. Rep.,* 1903, 133.

The taste and medicinal activity of pepper depend mainly on the concrete oil or resin, and on the volatile oil. The concrete oil is of a deep green color, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colorless, becoming yellow by age, of a strong odor, and of a taste less acrid than that of pepper itself. It consists of terpenes including dipentene, phellandrene, etc., and it forms a liquid but not a solid compound with hydrochloric acid. According to Weigle (*Ap. Ztg.,* 1893, 626), pepper contains, besides cellulose, starch, and coloring matter, (1) Volatile oil, smelling strongly of pepper, but without pungency; (2) a thick oil, tasteless and nearly odorless; (3) odorless piperine whose solutions possess the pungency of pepper. Weigle believes that in the fresh fruit the volatile oil acts as a solvent for the piperine and he thus accounts for their pungency.

For a paper on commercial peppers, by J. W. Gladhill, see *A. J. P.*, 1904, 71.

Adulterations.—On account of its extensive use as a condiment, pepper has been largely adulterated, especially when sold in the form of a powder. Chief of the adulterants are pepper-hulls, ground olive pits, wheat middlings, and roasted cereals. Among the other substances sometimes used have been ground beans or peas, corn starch, flaxseed, mustard hulls, and coffee hulls. The adulterated articles are usually fortified with the addition of Cayenne pepper. At the present time, by virtue of the National and state Food Laws, black pepper is seldom adulterated. Adulterations can be detected by the microscope with more or less ease (see *P. J.*, lxxi, 269; *P. J.*, June, 1890; *Bull. U. S. Dept. of Agriculture*, No. 13, Part II, pp. 183, 1887; *A. J. P.*, 1887, 146); but when pepper has been adulterated to the amount of 10 per cent. the discovery of the fraud is best made by determining the proportion of ash, of ether extract and of piperine present. The ash should never be above 6.5 per cent. for black and 3 per cent. for white pepper; the ether extract should be between 7.5 and 10 per cent. for black and 6 to 9 per cent. for white pepper, the U. S. standard being not less than 6 per cent. in which not less than 3.25 per cent. nitrogen shall be present. Piperine should be present in from 5.5 to 9 per cent. in good black pepper. The amount of oleoresin in any pepper can readily be determined by subtracting the weight of piperine from that of the mixture. Penang pepper is sometimes made to resemble the higher priced white peppers by coating the grains with an earthy matter (lime or clay). According to A. Mennechet, the fruits of *Myrsine africana* and of *Embelia Ribes* may sometimes be detected in the powder of pepper by extracting with ether and adding a little water, followed by a few drops of ammonia, when after shaking, a deep lilac-red color will appear in the aqueous layer. (*J. P. C.*, xiv, 587.)

Uses.—Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been used as a condiment and in medicine. Its chief medicinal application is to excite the languid stomach and correct *flatulence*. It was for years occasionally administered for the cure of *intermittents*, but its employment for this purpose had passed from the profession to the laity, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. Piperine has also been employed in the same disease, and has even been thought superior to quinine sulphate, but experience has not confirmed this favorable opinion. That, in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt, but it is not comparable to the preparations of cinchona, and is certaintly less active than the official oleoresin of pepper. In intermittent fever, pepper may be found a useful adjuvant to the more powerful febrifuge. It may be given whole or in powder, but is more energetic in the latter state.

Dose, of pepper, five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Confectio Piperis, *Br.;* Oleoresina Piperis, *U. S.;* Pulvis Opii Compositus, *Br.;* Tinctura Antiperiodica, *N. F.;* Tincture Antiperiodica sine Aloe, *N. F.*

PIX CARBONIS PRÆPARATA. Br.

PREPARED COAL TAR

(pĭx cär'bŏ-nĭs præ-pą-rā'tą)

"Prepared Coal Tar is obtained by maintaining commercial coal tar at a temperature of 50° C. (122° F.) in a shallow vessel for one hour, stirring frequently." *Br.* "The tar obtained as a by-product in the destructive distillation of coal in the manufacture of illuminating gas." *N. F.*

Pix Lithanthracis, *N. F.;* Coal Tar.

When bituminous coal is subjected to dry distillation, besides the incondensible gases which serve for lighting, and the charcoal left behind as coke, which is a valuable fuel, there are formed numerous other pyrogenic products, necessarily more or less varying in character and amount, not only according to the kind of coal used, but also with the varying circumstances of the decomposing process. Most of these newly formed bodies, all of which are volatile, are condensed into a dark thick liquid or semi-liquid substance called *coal tar*. Formerly this was considered as refuse matter, but from it are now prepared substances of great value in the arts and in medicine. We can give here only a brief review of the more important of these substances.

The composition of coal tar varies considerably with the temperature at which the distillation of the coal is effected, the yield of solid bodies and of gases being larger when the temperature is higher, while at a lower temperature the liquid portion of the tar is in increased amount. When coal tar is submitted to distillation and rectification, it yields the following products, solids, liquids, and gases, in variable proportion:

1. *Solids.*—Naphthalene, $C_{10}H_8$, methyl-naphthalene, $C_{11}H_{10}$, naphtha-ethylene and diphenyl, $C_{12}H_{10}$, fluorene, $C_{13}H_{10}$, anthracene and phenanthrene, $C_{14}H_{10}$, fluoranthene, $C_{15}H_{10}$, methyl-anthracene, $C_{15}H_{12}$, retene, $C_{18}H_{12}$, chrysene, $C_{18}H_{12}$, pyrene, $C_{16}H_{10}$, picene, $C_{22}H_{14}$, and carbazol, $C_{16}H_{11}N$.

2. *Liquids.*—These may be neutral hydrocarbons, acids, and ethers of the same, or bases. The *neutral hydrocarbons* are benzene, C_6H_6, toluene, C_7H_8, methyl-toluene, and iso-xylene, C_8H_{10}, pseudocumene, and mesitylene, C_9H_{12}, cymene, $C_{10}H_{14}$. The *acid constituents* are phenol, C_6H_6O, orthocresol, paracresol, and meta-

cresol, C_7H_8O, phlorol, $C_8H_{10}O$, rosolic acid, $C_{20}H_{16}O_3$, pyrocatechin, $C_6H_6O_2$, and creosote, consisting of the methyl ethers of pyrocatechin and its homologues, $C_7H_8O_2$, $C_8H_{10}O_2$, and $C_9H_{12}O_2$. There are also present, probably in combination with the ammonia of the ammoniacal liquor, acetic, butyric, carbonic, hydrocyanic, sulphocyanic, and hydrosulphuric acids. The *bases* are ammonia, NH_3, methylamine, $CH_3.NH_2$, ethylamine, $C_2H_5NH_2$, phenylamine, $C_6H_5.NH_2$, pyridine, C_5H_5N, picoline, C_6H_7N, lutidine, C_7H_9N, collidine, $C_8H_{11}N$, leucoline, C_9H_7N, iridoline, $C_{10}H_9N$, cryptidine, $C_{11}H_{11}N$, acridine, $C_{12}H_9N$, coridine, $C_{10}H_{15}N$, rubidine, $C_{11}H_{17}N$, and viridine, $C_{12}H_{19}N$.

3. *Gases.* (1) *Illuminating gases.*—Acetylene, C_2H_2, ethylene, C_2H_4, propylene, C_3H_6, butylene, C_4H_8, allylene, C_3H_4, crotonylene, C_4H_6, terene, C_5H_8, and vapors of benzene, C_6H_6, styrolene, C_8H_8, naphthalene, $C_{10}H_8$, methylnaphthalene, hexane, C_6H_{14}, heptane, C_7H_{16}, and octane, C_8H_{18}.

(2) *Heating and diluting gases.*—Hydrogen, H_2, marsh-gas (methane), CH_4, carbon monoxide, CO.

(3) *Impurities.—Carbon dioxide,* CO_2, ammonia, NH_3, cyanogen, $(CN)_2$, methyl cyanide, $CH_3.CN$, sulphocyanic acid, CN,SH, hydrogen sulphide, H_2S, carbon disulphide, CS_2, carbon oxysulphide, COS, and nitrogen, N_2.

For description of coal-tar colors and derivatives, see Part II.

Properties.—Prepared coal tar is "a nearly black, viscous liquid, brown in very thin layers; heavier than *water.* Strongly empyreumatic characteristic odor. Almost entirely soluble in *benzene* and in *chloroform;* partially soluble in *alcohol* (90 per cent.), and in *ether;* very slightly soluble in *water.*" *Br.*

"A nearly black, thick liquid or semi-solid, heavier than water and possessing a characteristic, naphthalene-like odor and a sharp burning taste. It is only slightly soluble in water, to which it imparts its characteristic odor and taste and a faintly alkaline reaction. It is but partially dissolved by alcohol, acetone, methyl alcohol, or purified petroleum benzin; almost entirely dissolved by ether; entirely dissolved by benzene, carbon disulphide, or chloroform. On ignition it burns with a reddish, luminous and very sooty flame and upon strong heating is almost entirely consumed, leaving not more than 2 per cent. of ash." *N. F.*

Uses.—Coal-tar is occasionally used as a substitute for wood-tar in external applications, and according to Dind (*An. de Derm. et de Syph.,* 1909), has advantages over wood-tar that it is less irritant and less likely to produce nephritis or other toxic conditions after absorption. It is employed locally to relieve *itching* and to combat inflammation in such diseases as *lichen ruber, prurigo, eczema,* etc. It should not be used where the skin is infected with pyogenic cocci. It is most frequently applied in solution combined with saponin. (See *Liquor Picis Carbonis.*)

Off. Prep.—Liquor Picis Carbonis *Br.*

PIX LIQUIDA. U. S., Br.

TAR Pix Liq. [Pine Tar]

(pĭx lĭq'uĭ-dȧ)

"A product obtained by the destructive distillation of the wood of *Pinus palustris* Miller, or of other species of *Pinus* (Fam. *Pinaceæ*)." *U. S.* "Tar is a bituminous liquid, obtained by destructive distillation from the wood of Pinus sylvestris, *Linn.,* and other species of Pinus. Known in commerce as Stockholm tar." *Br.*

Resina Empyreumatica Liquida; Goudron végétal, *Fr. Cod.;* Goudron, *Fr.;* Theer, *G.;* Pece liquida, *It.;* Brea de pino, Alquitran vegetal, *Sp.*

The tar used in this country is prepared from the wood of various species of pine, particularly *Pinus palustris,* or the long-leaved, yellow or Georgia pine, of the Southern States. (See *Terebinthina.*) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concreted in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile and then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the center, where a cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into a cavity in the center of the mound, and passes thence by the conduit into the ditch, whence it is transferred into barrels. Immense quantities of tar are thus prepared in North Carolina and the southeastern parts of Virginia, sufficient, after supplying our own consumption to afford a large surplus for exportation. Considerable quantities of tar have been prepared also in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Allegheny Mountains, from the *Pinus rigida,* or pitch pine, and perhaps from some other species.

Properties.—Tar has an acid reaction, a peculiar empyreumatic odor, a bitterish, resinous, somewhat acrid taste, a color almost black, and a tenacious consistence intermediate between that of a liquid and that of a solid; by age it becomes granular and opaque. It consists of resinous matter, united with acetic acid, oil of turpentine, and various volatile empyreumatic products, and colored with charcoal. By distillation it yields an acid liquor called *pyroligneous acid* (see *Acidum Aceticum*), and an empyreumatic oil called *oil of tar;* what is left behind is *pitch.* It is officially described in the United States Pharmacopœia as "semi-liquid, viscid, blackish-brown, non-crystalline, translucent in thin layers, becoming granular and opaque with age; odor empyreumatic, terebinthinate, taste sharp and empyreumatic. Tar is miscible with alcohol, ether, chloroform, glacial acetic acid, or fixed or volatile oils; it is heavier

than water and is slightly soluble in it, the solution being of a pale yellowish to yellowish-brown color and acid to litmus. The addition of a drop of ferric chloride T.S. to 10 mils of an aqueous solution of tar produces a greenish-brown color." *U. S.*

"Dark brown or nearly black; semi-liquid; empyreumatic characteristic odor; heavier than *water*. *Water* shaken with it acquires a pale-brown color, sharp empyreumatic taste, and acid reaction; very dilute *T. Sol. of ferric chloride* colors the solution red. Tar is completely soluble in ten times its volume of *alcohol* (90 per cent.)." *Br.*

The first examination of the empyreumatic oil was made by Reichenbach, of Moravia, who found a variety of substances, to which he gave the names of *paraffin, eupion, creosote, picamar, capnomor,* and *pittacal.* It has been found by more careful study of wood tar that it contains a great variety of compounds, including the hydrocarbons *toluene,* C_7H_8, *xylene,* C_8H_{10}, *mesitylene* and *pseudocumene,* C_9H_{12}; phenols like common *phenol,* C_6H_6O, *cresol,* C_7H_8O, *guaiacol,* $C_7H_8O_2$, *creosol,* $C_8H_{10}O_2$, *phlorol,* $C_8H_{10}O$, and *methylcreosol,* $C_9H_{12}O_2$, the last four constituting the mixture known as creosote; and, lastly, *paraffin* in variable quantity, depending upon the temperature of distillation, *naphthalene,* $C_{10}H_8$, *pyrene,* $C_{16}H_{10}$, *chrysene,* $C_{18}H_{12}$, and *retene,* $C_{18}H_{18}$. *Pyrocatechol,* $C_6H_4(OH)_2$, is also obtained, either in the pyroligneous acid, as it is soluble in water, or in the tarry mixture. It crystallizes readily, fuses at 104° C. (219.2° F.), and sublimes at a temperature slightly above this. Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water* (see below). Tar is dissolved by alcohol, ether, chloroform, and the volatile and fixed oils, and by a solution of potassium or sodium hydroxides. On spreading tar in a thin layer on a pane of glass it should present a homogeneous appearance. Those specimens which contain granular transparent masses should be rejected. These masses, which polarize brilliantly, are said to be *pyrocatechol.* Tar should have a specific gravity of 1.03 to 1.07; it should boil at from 250° to 400° C. (482°–752° F.). Its reaction should be acid. "*Steam refined tar*" is tar which has been simply heated in steam caldrons and strained to remove foreign impurities.

Hirschsohn has suggested the following plan for the identification of different varieties of tar. (1) *Completely soluble in 95 per cent. acetic acid. Pine Tar.*—French turpentine dissolves it completely. The petroleum ether extract of the tar is colored greenish when shaken with a dilute solution of cupric acetate (1 : 1000). Chloroform and absolute ether dissolve it completely. *Beech Tar.*—Turpentine oil dissolves it only partially. The petroleum ether extract is not colored by copper acetate solution. Chloroform and absolute ether do not entirely dissolve it. (2) *Not completely soluble in 95 per cent. acetic acid. Juniper Tar.*—Turpentine oil dissolves it completely. Aniline dissolves it completely. The aqueous extract (1 : 20) yields a red coloration with dilute solution of ferric chloride (1 : 1000). *Birch Tar.*—Turpentine oil dissolves it completely. Aniline does not dissolve it completely. The aqueous extract is colored greenish by ferric chloride. *Aspen Tar.*—Benzene, chloroform, absolute ether, and olive oil dissolve it only partially. (*Ph. Ztg.,* 97, 396; *Ph. Z. R.,* 97.)

The pitch left after the evaporation of tar was formerly official with the British Colleges, under the names of *Pix nigra, Pix arida,* or simply *Pix.* It has a shining fracture, softens and becomes adhesive with a moderate heat, melts in boiling water, and consists of the unaltered resin of the pine and of various empyreumatic resinous products which have received the name of *pyretin.* (Berzelius, *Traité de Chimie,* vi, 641, 680.) It has been used internally in *ichthyosis* and other cutaneous diseases, and in *piles.* The dose is from ten grains to a drachm (0.65–3.9 Gm.), given in pill. Pitch is also used externally in the form of ointment.

Uses.—Tar owes its medicinal virtues chiefly to the phenol-like bodies which it contains; its effects resemble closely those of creosote, but it is less active and less liable to irritate the digestion. It is occasionally employed as a urinary antiseptic, but its most important internal use is as a stimulating expectorant in subacute or chronic bronchitis. Externally it is widely employed as a stimulating and antiseptic application in various *skin diseases.* (See *Unguentum Picis Liquidæ.*)

In reference to the administration of tar, it has always been considered desirable to have it in a soluble state, so that it might be brought with facility into a liquid form if required. Besides, tar in the stomach will probably be found efficacious in proportion to its solubility. This desired end was attained when it was discovered that tar was capable of forming a definite, solid compound with sugar which was very soluble in water. Saccaharated tar contains 4 per cent. of pure tar, resembles sugar in appearance, having a sweet taste and the odor of tar, and may be given in substance or solution as deemed desirable. (*P. J.,* Sept., 1871.) (See *Syrupus Picis Liquidæ.*) But glycerin is a more convenient vehicle, and glycerite of tar was an official preparation in 1870. Its vapor, inhaled into the lungs, may be serviceable in *chronic bronchitis* and *phthisis.* Its effects are most conveniently obtained by placing tar or oil of tar in a tin dish containing hot water, and heating this; the fumes may be inhaled by inverting a funnel to which a rubber tube is attached, over the dish. Tar was formerly used to a considerable extent in the form of *tar water, Infusum Picis Liquidæ,* U. S., 1870. This was made by macerating one part of tar in four parts of water with frequent agitation and decanting the clear fluid. Tar water is "a pale yellowish-brown color and acid reaction, and yields with ferric chloride test solution a transient green color, and is colored brownish-red by

an equal volume of calcium hydrate test solution." Two or three fluidounces (59–89 mils) of this infusion may be given several times a day. Tar may also be administered mixed with sugar in the form of an electuary.

Pulverulent tar is prepared by Magnes-Lahens, by mixing, in an earthenware vessel, two parts of finely divided charcoal and one part of liquid tar. The resulting mixture resembles small grains of gunpowder, does not soil the vessel or the fingers, and yields readily to water the tar which it contains—the most favorable temperature for solution being about 20° C. (68° F.). Magnes-Lahens recommends a syrup prepared from the powder as follows. Take of pulverulent tar, 50 Gm., water, 180 Gm., granulated sugar, 320 Gm. Mix the tar and sugar in a mortar, then add the water, and heat the mixture by a water bath at 60° C. (140° F.). Then remove from the bath, shake until the sugar is all dissolved, and strain when hot, and afterwards again when cold. A tablespoonful of the syrup, added to a tumbler of water, yields a tar water resembling that of the French Codex. The pulverulent tar may also be used for pills. (*P. J.*, April, 1872, 850.)

Dose, five to twenty grains (0.32–1.3 Gm.).

PLUMBI ACETAS. U. S., Br.

LEAD ACETATE Plumb. Acet. [Sugar of Lead]

(plŭm'bī ă'cę-tăs)

"It contains not less than 85.31 per cent. nor more than 89.57 per cent. of anhydrous lead acetate, corresponding to not less than 99.5 per cent. of the crystallized salt [$Pb(C_2H_3O_2)_2 + 3H_2O = 379.20$]. Preserve it in well-closed containers." *U. S.* "Lead acetate may be obtained by dissolving lead oxide or lead carbonate in acetic acid. It contains not less than 99.5 per cent. of pure lead acetate, $Pb(C_2H_3O_2)_2,3H_2O$." *Br.*

Acetas Plumbicus, Saccharum Saturni, Cerussa Acetata; Acétate neutre de Plomb, Sucre de Plomb, Sel de Saturne, *Fr. Cod.;* Plumbum Aceticum, *P. G.;* Bleiacetat, Essigsaures Bleioxyd, Bleizucker, *G.;* Acetato neutro di plombo, Zucchero di Saturno, *It.;* Acetato plumbico neutro, Azucar de Saturno, *Sp.*

Preparation.—Lead acetate is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar, and these are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal, in the presence of the oxygen of the air, dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, in 60 per cent. acetic acid, in large wooden vats provided with mechanical stirrers. The acetic acid is heated to 60° C. (140° F.) and the litharge added by means of a distributing device. The oxide is quickly dissolved, and, when the acid has become saturated, the solution is permitted to clarify by subsidence in vessels provided with strips of lead which coming into contact with the solution remove small amounts of copper which may be present, and it is then transferred to other vessels to cool and crystallize. The crystals having formed, the mother waters are decanted, and, by evaporation, made to yield a new crop. These are generally yellow, but may be rendered white by repeated solutions and crystallizations.

Lead acetate is extensively manufactured in Germany, Holland, France and England, as well as in the United States. It is principally consumed in the arts of dyeing and calico printing, in which it is employed with alum, to form aluminum acetate, which acts as a mordant.

Properties.—"Lead Acetate occurs as colorless, shining, transparent, monoclinic prisms or plates, or as heavy, white, crystalline masses, or granular crystals, having a faintly acetous odor, and a sweetish, astringent, afterwards metallic taste; efflorescent, and absorbing carbon dioxide on exposure to the air. One Gm. of Lead Acetate dissolves in 1.4 mils of water, and in 38 mils of alcohol at 25° C. (77° F.); also in about 0.5 mil of boiling water; freely soluble in glycerin. When heated to 40° C. (104° F.) the salt loses its water of crystallization. When heated rapidly to 75° C. (167° F.) it fuses in its water of crystallization, and at a temperature above 280° C. (536° F.) it finally decomposes, leaving a residue of finely divided metallic lead mixed with lead oxide. An aqueous solution of Lead Acetate (1 in 10) is slightly alkaline to litmus and separate portions yield a black precipitate with hydrogen sulphide T.S., a yellow precipitate with potassium iodide T.S., and a white precipitate with diluted sulphuric acid. Add 0.1 Gm. of the salt to a mixture of 1 mil of sulphuric acid and 1 mil of alcohol and warm the mixture; ethyl acetate is formed, recognizable by its odor. A solution of the salt (1 in 10), prepared with distilled water which has been recently boiled, is clear, or only slightly opalescent (*carbonate*) and yields with potassium ferrocyanide T.S. a precipitate which is not perceptibly blue or red (*iron or copper*).

"**Assay.**—Dissolve about 5 Gm. of Lead Acetate, accurately weighed, in sufficient recently boiled distilled water to make exactly 100 mils of solution. Mix 10 mils of this solution with 50 mils of tenth-normal oxalic acid V.S. in a 200 mil measuring flask, agitate the mixture thoroughly for five minutes, then fill the flask to the mark with distilled water; filter, and titrate 100 mils of the filtrate (representing one-twentieth of the amount of Lead Acetate originally taken) with tenth-normal potassium permanganate V.S., the filtrate being previously acidulated with 10 mils of sulphuric acid and warmed to 80° C. (176° F.). It shows not less

than 85.31 per cent. nor more than 89.57 per cent. of $Pb(C_2H_3O_2)_2$.

"Each mil of tenth-normal oxalic acid V.S. used corresponds to 0.016257 Gm. of $Pb(C_2H_3O_2)_2$. Each gramme of Lead Acetate corresponds to not less than 52.5 mils nor more than 55.1 mils of tenth-normal oxalic acid V.S." *U. S.*

"Small, white, monoclinic prisms, or crystalline masses, slightly efflorescent. Acetous odor; taste sweet, astringent. Soluble in 2.5 parts of *water,* and in 30 parts of *alcohol* (90 per cent.). Aqueous solution slightly acid to *litmus,* clear, or with only a slight turbidity which disappears on the addition of *acetic acid.* Yields the *reactions* characteristic of lead and of acetates. Yields no characteristic *reactions* for silver, copper, arsenic, iron, zinc, calcium, chlorides, or nitrates. When 0.5 gramme is dissolved in *water* acidified with *acetic acid,* excess of *N/1 solution of oxalic acid* added, the precipitate collected, washed, transferred to a flask and decomposed with excess of *diluted sulphuric acid,* the mixture thus obtained, heated to 60° C. (140° F.), decolorises not less than 26.2 millilitres of *N/10 solution of potassium permanganate* (presence of not less than 99.5 per cent. of pure lead acetate, $Pb(C_2H_3O_2)_2,3H_2O$)." *Br.*

Exposed to the air, it effloresces slowly. In pure distilled water, free from carbon dioxide, it ought to dissolve entirely and form a clear solution. Commercial acetate is sometimes impure from the presence of lead sulphate and carbonate. In purchasing it large crystalline masses should be selected. Sulphuric acid, when added to a solution of lead acetate, produces instantly a precipitate of lead sulphate, and the disengaged acetic acid gives rise to vapors having the odor of vinegar. An important property of lead acetate is its power of dissolving a large quantity of lead monoxide. (See *Liquor Plumbi Subacetatis.*) It consists of one atom of lead, which has replaced the two hydrogen atoms furnished by two molecules of acetic acid, $C_2H_3O_2.H$, so that its formula becomes $Pb(C_2H_3O_2)_2$, and this in crystallizing takes $3H_2O$. Its molecular weight is therefore 376.15.

Incompatibles and Tests.—Lead acetate is decomposed by all acids, and by those soluble salts the acids of which produce with lead monoxide insoluble or sparingly soluble compounds. Acids of this character are sulphuric, hydrochloric, phosphoric, tannic, citric, and tartaric. It is also decomposed by lime water, and by ammonia, potassium and sodium hydroxides; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the calcium sulphate, carbonates and sodium chloride which such water usually contains.

Uses.—Lead acetate, in medicinal doses, is a powerful astringent and sedative; in overdoses, an irritant poison, which has in a number of cases caused death. Burning epigastric pain, vomiting of a white curdy matter (lead chloride), and diarrhea or constipation with black stools (lead sulphide), and finally collapse, are the characteristic symptoms. Its antidote is any soluble sulphate, common salt, soap, or an alkali.

In medicinal doses lead acetate is a powerful sedative astringent. It is especially useful in the treatment of *diarrheas,* and even of *dysentery,* when the discharges are excessive. At one time it was very much used for the relief of *gastric* or *intestinal hemorrhages,* but is rarely employed for this purpose to-day. In many cases of *chronic diarrhea* or in *diarrheas* occurring in exhaustive, uncontrollable disease, such as *phthisis,* lead acetate, combined with opium, may be a valuable palliative in checking discharges. Externally it has been applied in weeping *eczema,* in *pruritus vulvæ,* and similar conditions of irritation, but is less frequently employed than formerly. The prolonged medicinal use of acetate of lead may give rise to subacute or chronic lead poisoning.

Internally, lead acetate should always be given in the form of pill, and is often combined with opium. The solution for external use may be made by dissolving from two to three drachms in a pint of water, and, if it be wanted clear, a fluidrachm of vinegar or of diluted acetic acid may be added, which immediately dissolves the lead carbonate, to which its turbidity is owing. When the skin is denuded of the cuticle, the solution should be weaker. The usual strength of the solution as a collyrium is from one to two grains (0.065–0.13 Gm.) to the fluidounce (30 mils) of *distilled* water. In this case, acetic acid should not be used to clear up the solution, which should simply be filtered.

Dose, one to three grains (0.065–0.20 Gm.).

PLUMBI IODIDUM. Br.

LEAD IODIDE

(plŭm'bī ī-ŏd'ĭ-dŭm)

"Lead Iodide, PbI_2, may be obtained by the interaction of aqueous solutions of lead nitrate or acetate and potassium iodide." *Br.* "It contains not less than 99 per cent. of PbI_2 (460.94). Preserve it in well-closed containers, protected from light." *N. F.*

Plumbum Iodatum, Ioduretum Plumbicum, Iodure de Plomb, *Fr. Cod.;* Jodblei, *G.;* Yoduro plumbico, *Sp.*

"Take of Nitrate of Lead, Iodide of Potassium, each *four ounces* [avoirdupois]; Distilled Water *a sufficiency.* Dissolve the Nitrate of Lead, by the aid of heat, in a pint and a half, and the Iodide of Potassium in half a pint of the Water, and mix the solutions. Collect the precipitate on a filter, wash it with Distilled Water, and dry it in a warm place." *Br.,* 1885.

No process was given in the U. S. P. VIII nor Br. Ph., 1914, for lead iodide. The process of the U. S. P., 1870, was identical with that of the British Pharm., 1885, given above.

The lead nitrate gives up its metal to the iodine, receiving the potassium, the operation taking place between one molecule of the lead nitrate and two molecules of the potassium iodide. The potassium nitrate thus formed remains in solution, while the lead iodide is precipitated,

$$Pb(NO_3)_2 + 2KI = 2KNO_3 + PbI_2$$

The theoretical quantities of lead nitrate and potassium iodide are 331.12 of the former and 332.04 of the latter, or almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the potassium iodide, independently of the waste, has the disadvantage of holding a portion of the lead iodide in solution, while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble lead oxyiodide. By the use of equal quantities of the two salts these disadvantages are avoided. As lead iodide is slightly soluble in cold water, it is desirable to use as little of the solvent as will answer, and hence the comparatively small proportion of water employed.

In the former London process lead acetate was employed instead of the nitrate, but Depaire, of Brussels, ascertained that in this process a considerable amount of iodide remains in solution after the precipitation of the lead iodide. Boudet (*J. P. C.*, 3e sér., xi, 274) ascribes this result to the formation of a portion of soluble potassium and lead iodide, whenever lead iodide and potassium acetate are in contact. T. Huraut has found that of the two lead salts employed, the nitrate was to be preferred, and of the various iodides, though potassium iodide yielded a very handsome product, yet calcium iodide afforded one not inferior in quality, and somewhat greater in quantity. Upon a small scale, as the process is performed by the apothecary, the difference would be of little consequence, but it might be important to the manufacturer. (See *A. J. P.*, xxi.)

Properties.—As officially described, it is in the form of "a heavy, bright-yellow powder. Soluble in about 2000 parts of cold *water*, and in about 200 parts of boiling *water*, from which it is deposited in golden-yellow crystalline scales as the solution cools; entirely soluble in *solution of ammonium chloride*. Yields the *reactions* characteristic of lead and of iodides. Yields no characteristic *reactions* for nitrates or acetates." *Br.*

"Lead Iodide occurs as a heavy, bright yellow powder, without odor or taste; permanent in the air. One gramme dissolves in about 1300 mils of water at 25° C. (77° F.) and in about 200 mils of boiling water, separating from the latter solution on cooling in brilliant, golden-yellow crystalline laminæ; very slightly soluble in alcohol; soluble, without color, in solutions of the fixed alkalies, in concentrated solutions of the alkali acetates, of potassium iodide, and of sodium thiosulphate, and in a hot solution of ammonium chloride. When moderately heated, the salt fuses to a thick, reddish-brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed, with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide. Triturate 1 Gm. of the salt with 2 Gm. of ammonium chloride and 2 mils of distilled water; a nearly white mixture results. Transfer this to a test tube, and heat in a water bath for a few minutes; a clear, almost colorless solution is formed (*chromate and other insoluble foreign salts*). On cooling this solution, a solid mass of nearly colorless, fine, silky crystals is produced, and on adding water or diluted sulphuric acid to this mass, yellow Lead Iodide separates. Add 0.1 Gm. of the salt to 5 mils of distilled water, and heat the mixture until it boils; cool the liquid and filter it into a test tube of about 40 mils capacity, then add 5 mils of sodium hydroxide T.S. and about 0.2 Gm. of aluminum wire; insert in the upper portion of the test tube a pledget of purified cotton, and over the mouth place a piece of moistened red litmus paper and then heat the tube on a water bath during fifteen minutes; no blue coloration of the paper will be discernible (*nitrate*). Boil 1.5 Gm. of Lead Iodide for a few minutes with 15 mils of distilled water, cool and filter. To 5 mils of the filtrate add a slight excess of silver nitrate T.S., then a slight excess of hydrochloric acid and filter. Neutralize the filtrate with ammonia water and add a drop of ferric chloride T.S. No red color is produced (*acetate*). To another 5 mil portion of the filtrate add an excess of hydrogen sulphide T.S., filter, evaporate to dryness and ignite; not more than 0.002 Gm. of residue remains." *N. F.*

It is freely soluble in a concentrated solution of sodium acetate. (Donato Tommasi, *P. J.*, 3d series ii, 805). It should be kept excluded from the light. It is stated by Engelhardt that iodine is separated from lead iodide by ferric and cupric chlorides, while the other metallic chlorides have no such effect, producing compounds of iodides of the metal employed with lead chlorides.

Uses.—This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and is said to have been usefully employed in the discussion of *scrofulous tumors* and other indolent swellings, and in the cure of obstinate *ulcers*, both internally and locally. According to Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. It is more dangerous than useful. The plaster of lead iodide was dropped from the British Pharm., 1914, but the ointment was retained.

Dose, half a grain to four grains (0.032–0.26 Gm.).

Off. Prep.—Unguentum Plumbi Iodidi, *Br.*

PLUMBI OXIDUM. U. S., Br.

LEAD OXIDE Plumb. Oxid. [Litharge]

(plŭm'bī ŏx'ĭ-dŭm)

"It contains, when freshly ignited, not less than 96 per cent. of PbO (223.10). Preserve it in well-closed containers." *U. S.* "Lead Oxide, PbO, may be obtained by the action of air on melted lead." *Br.*

Oxide of Lead; Lithargyrum, Plumbum Oxydatum, Plumbi Oxidum Semivitreum; Oxide (proto) de Plomb fondu, Litharge, *Fr. Cod.*; Protoxide de Plomb, *Fr.*; Bleiglätte, Bleioxyd, *G.*; Litargirio, *It.*, *Sp.*

When lead oxide is rendered semi-crystalline by incomplete fusion it becomes the *semi-vitrified oxide*, or litharge. Almost all the litharge of commerce is obtained, as a secondary product, in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is placed upon an oval slightly concave dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone ash, formed into a paste with water, into a mould, the sides of which consist of an elliptical band of iron, and the bottom of strips of sheet iron, placed at short distances apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed and adjusted to the level of the floor. On one side of the test the fireplace is situated, and exactly opposite, the chimney, while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the test. The furnace is now lighted, and shortly afterwards the bellows are put in motion. The lead fuses and combines with oxygen, and the resulting oxide, melting also, forms a stratum which floats on the surface, and which is driven by the blast of the bellows along the gutter and through the vertical hole into a receiver below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and blown off the test, fresh portions are added so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test, and, the oxidation proceeding, a period at last arrives when the whole of the lead has been blown off as litharge, and the silver, known to be pure by it brilliant appearance in the fused state, alone remains. This is then removed, and the process repeated on a fresh portion of argentiferous lead. The yellow amorphous lead oxide as a paint color is known as *massicot*, and is prepared by careful heating of lead carbonate or nitrate to a point short of the fusion of the resulting oxide.

Properties.—It is officially described as "a heavy, yellowish or reddish-yellow powder, or in minute scales, without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide. Lead Oxide is almost insoluble in water, to which, however, it imparts a faintly alkaline reaction; insoluble in alcohol; dissolved by acetic or diluted nitric acid, and by warm solutions of the fixed alkali hydroxides. When heated, the Oxide becomes darker in color, but assumes its original color on cooling; it fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead. A solution of the Oxide in diluted nitric acid (1 in 10) is colorless, and, when nearly neutralized by ammonia water, separate portions yield with hydrogen sulphide T.S. a black precipitate, with potassium iodide T.S. a yellow precipitate, and with diluted sulphuric acid a white precipitate. Shake 5 Gm. of the Oxide in a small flask with 5 mils of distilled water, and add 20 mils of acetic acid. Boil the mixture for a few minutes, filter it, wash the insoluble residue well with diluted acetic acid, and dry it at 110° C. (230° F.); it weighs not more than 0.15 Gm. When strongly heated in a porcelain crucible, the Oxide loses not more than 4 per cent. of its weight (*carbonate and moisture*)." *U. S.*

"Heavy scales, or powder, of a pale yellowish-red color. Soluble in *diluted nitric acid* and in *acetic acid* with but slight effervescence, leaving not more than traces of insoluble residue. Yields the reactions characteristic of lead. Yields no characteristic *reactions* for copper, and not more than the slightest *reactions* for iron." *Br.*

It slowly attracts carbon dioxide from the air, and contains more of this acid the longer it has been exposed. It is on this account that it commonly effervesces slightly with the diluted acids. It has the property of decolorizing wines, when agitated with them. When heated with the fats and oils, in connection with water it saponifies them. (See *Emplastrum Plumbi.*) Heated with charcoal, it is reduced to the metallic state. In diluted nitric acid it should be almost entirely soluble; and the solution is affected by potassium hydroxide in the same manner as that of the carbonate. (See *Plumbi Carbonas.*) As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. It may be purified from iron and copper by digestion in diluted sulphuric acid. The English litharge is most esteemed, that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper and from fragments of vegetable matter. Copper is detected if upon adding potassium ferrocyanide to a nitric acid solution of the litharge a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their color, and dependent on differences in the process employed. Sometimes it has a pale yellow color and silvery appearance, and is then denominated *argyritis, silver litharge* or *yellow litharge*; at other times it is of a red color, and is known under the names of *crystitis, gold litharge* or *red litharge*. The latter was supposed to owe its color to the presence of a portion of red lead, but Leblanc has shown that the two varieties of litharge differ in color, structure, and density only, and not in chemical composition. In this respect litharge

is essentially identical with lead oxide. (See *Plumbum.*) The carbon dioxide which it contains is variable, but its average amount is about 4 per cent. Lead peroxide and red lead in litharge may be detected by heating it in a test tube with sodium chloride and potassium bisulphate and introducing a slip of paper colored blue by indigo. If either of these oxides be present, the paper will be bleached by the chlorine evolved.

"**Assay.**—Dissolve about 0.4 Gm. of freshly ignited Lead Oxide, accurately weighed, in 4 mils of acetic acid and 25 mils of recently boiled distilled water, in a 200 mil graduated flask, and mix the solution with 50 mils of tenth-normal oxalic acid V.S. Fill the flask to the mark with distilled water, mix well, filter through a dry filter into a dry flask, rejecting the first 20 mils of filtrate, and titrate 100 mils of the filtrate (representing one-half of the amount of Lead Oxide originally taken) with tenth-normal potassium permanganate V.S., the filtrate being previously acidulated with 20 mils of diluted sulphuric acid and warmed to 80° C. (176° F.). It shows not less than 96 per cent. of PbO.

"Each mil of tenth-normal oxalic acid V.S. corresponds to 0.011155 Gm. of PbO. Each gramme of Lead Oxide, after ignition, corresponds to not less than 86.1 mils of tenth-normal oxalic acid V.S." *U. S.*

Uses.—Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, used for abating inflammation, and for other purposes. In the arts it is employed in the glazing of pottery, in painting to increase the drying property of oils, and as an ingredient in flint glass.

PLUMBUM

LEAD

(plŭm'bŭm)

Plomb, *Fr.;* Blei, *G.;* Lood, *Dutch;* Piombo, *It.;* Plomo, *Sp.*

Lead is not official in its metallic state, but enters into a number of important medicinal preparations. It occurs in nature as an oxide, as a sulphide called *galena,* and in saline combinations, forming the native lead sulphate, phosphate, carbonate, chromate, molybdate, tungstate, and arsenate. The oxide is rare, but galena is exceedingly abundant, and is the ore from which nearly all the lead of commerce is extracted. The extraction is effected either by melting the ore in contact with charcoal, or, in the case of pure galenas, by what is termed the *air reduction* process. In this case the galena is first roasted, when it is in part changed into oxide, PbO, and sulphate, $PbSO_4$. The doors of the furnace are then closed, and the unchanged sulphide reacts with both the oxide and the sulphate as follows:

$$2PbO + PbS = 3Pb + SO_2$$
$$PbSO_4 + PbS = 2Pb + 2SO_2$$

whereby all the lead is obtained in the metallic state. Lead is also successfully obtained by electrolysis directly from the galena. This is reduced at the cathode of an electrolytic cell, while hydrogen sulphide is formed at the same time and may be collected or burned to form sulphur dioxide, which is then utilized. The process is now in operation at Niagara Falls. The richest and most extensive mines of galena are found in this country. The non-argentiferous lead region of the United States extends in length from Wisconsin in the north to the Red River of Arkansas in the south, and in breadth about one hundred and fifty miles, being chiefly in the State of Missouri, while Utah, Idaho, Montana, and Colorado furnish argentiferous galena. The total production of lead in the United States in 1915 was 615,253 tons, made up of 565,356 tons from domestic ores (317,463 from silver bearing lead ore and 247,893 from non-silver bearing), and 49,897 tons from imported ores.

Properties.—Lead is a soft, bluish-gray, and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar odor when rubbed. It undergoes but little change in the air, but is acted on by the combined influence of air and rain water, which gives rise to a hydrate, which is afterwards changed, in part, into carbonate, by absorbing carbon dioxide from the atmosphere, and if in water, the carbonate is imparted to it in the state of bicarbonate, which dissolves and renders the liquid poisonous. This chemical effect on the metal is greater in proportion as the water is purer. Aqueous vapor passed through leaden pipes has a similar corroding effect, which is greater as the lead is purer. Spring and river water act on lead differently, the lead becoming slowly oxidized, and covering itself with a black coating of suboxide, which adheres strongly to the metal, and thus in some measure protects the water. Hard water forms a protective coating of lead carbonate or lead sulphate on the inner surface of pipes through which it flows, but it is stated that this protective condition disappears in waters which have been treated with chlorine or hypochlorites for the purpose of purification. (Langlois, *J. P. C.*, 4e sér., ii, 29.) Stalmann has satisfied himself, by experiment, that an extremely minute quantity of ammonia or of nitric acid will very much promote the action of water upon lead—a millionth of ammonia being sufficient for the purpose. (*J. P. C.*, iv, 467.) Metallic lead seems to be liable to the attacks of certain insects, which bore into and sometimes through it, not using it as food, but apparently in search of secure places of retreat for future development. A knowl-

edge of this fact may sometimes be important. (*A. J. P.*, Jan., 1865, p. 72.) Its sp. gr. is 11.4, melting point 334° C. (633.2° F.), and atomic weight 207.10. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame throwing off dense yellow fumes. The best solvent of lead is nitric acid, but the presence of sulphuric acid destroys, and that of hydrochloric acid lessens, its solvent power, on account of the insolubility of the lead sulphate and chloride. Lead forms a suboxide, Pb_2O, a monoxide, PbO, a sesquioxide, Pb_2O_3, a dioxide, PbO_2, and a compound of the monoxide and the dioxide, which has a varying composition, but is usually Pb_3O_4. The *monoxide* is called in commerce *massicot*, or *litharge*.

On a large scale it is made by exposing melted lead to the action of the air. Its surface becomes encrusted with a gray pellicle, which, being scraped off, is quickly succeeded by another; and the whole of the metal, being in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of monoxide and metallic lead. This, on exposure to a moderate heat, absorbs more oxygen, and is converted wholly into monoxide. This oxide has a yellowish color, and is the only oxide capable of forming salts with the acids. It consists of one atom of lead and one of oxygen. *Litharge,* PbO, is very much used in pharmacy, and is official in all the Pharmacopœias. (See *Plumbi Oxidum.*) The *sesquioxide,* discovered by Winckelblech, is unimportant. The *dioxide,* PbO_2, called also *puce* oxide, from its flea-brown color, may be obtained by treating red lead with nitric acid. The acid takes up the monoxide and leaves the dioxide, which may be purified by washing with boiling water. A more productive process is to precipitate four parts of lead acetate by three of sodium carbonate, and then to pass into the thin pasty mass of lead carbonate a stream of chlorine, which converts the monoxide of the carbonate into the brown dioxide. (F. Wöhler.) Solution of chlorinated soda may be conveniently employed to furnish the necessary chlorine. Lead forms two classes of compounds in one of which it acts as a base (as illustrated by the official salts of lead), and in the other of which it is contained in the acid group forming a class of compounds known as *plumbates* and *plumbites;* Na_2PbO_2 and Na_2PbO_3, are examples of the sodium salts of this composition. Lead dioxide is a tasteless powder, of a dark brown color. When heated to redness it loses half its oxygen and becomes monoxide. It consists of one atom of lead and two atoms of oxygen. The *red oxide,* Pb_3O_4, called in commerce *minium,* or *red lead,* is described under another head. (See *Lead Oxide, Red,* Part II.) Lead combines with iodine, forming the official lead iodide. The acetate is also official.

The best tests for lead are hydrogen sulphide or a solution of potassium iodide. The former produces a black precipitate of lead sulphide, the latter a yellow one of lead iodide.

Poisoning.—In concentrated form and sufficient amount the soluble preparations of lead are violent irritant poisons. (See *Plumbi Acetas,* p. 873.) The insoluble preparations of lead are incapable of acting as acute irritant poisons, but are the common causes of a chronic poisoning. The most common form of the poisoning, the so-called *colica pictonum,* is very common among painters, makers of white lead, and other artisans who work in the metal. It is, however, also frequently seen in other persons, into whom the lead finds entrance in almost innumerable ways, especially with drinking water and food. Colica pictonum usually begins with dyspeptic symptoms and obstinate constipation, associated with violent pain of a twisting character, which seems to center round the umbilicus; the abdominal walls are spasmodically retracted.

Accompanying these symptoms there is loss of appetite, pallor, lassitude, and failure of the general health. The stools are whitish and usually constipated, although occasionally there is diarrhea. A characteristic symptom is a blue line situated upon the margin of the gums where they join the teeth, due to the deposit of the lead sulphide. This blue line, if present, is pathognomonic, but may be absent even in the most severe cases. Basophilic degeneration of the red blood cells can be found in the majority of cases, and if present is a very suggestive symptom. The pulse is usually slow and hard.

Various symptoms of disorder of the nervous system or of nutrition may occur later. Occasionally these nervous disturbances are the sole evidence of the intoxication, although more frequently they are either accompanied with, or preceded by, the typical lead colic. The most characteristic of the nervous phenomena is the double wrist drop due to paralysis of the extensors of the fore arm, and associated with wasting and degenerative changes in the muscles involved. Rarer manifestations are: paraplegia simulating anterior poliomyelitis; cerebritis with wild delirium and sometimes convulsions; occasionally arthritis very much like that of typical gout may be seen. Chronic lead poisoning in rare cases may take on many other forms; indeed, it has been said that lead poisoning may simulate any known nervous disease. For further information on chronic lead poisoning, see Hamilton (*J. A. M. A.*, 1911, lvi, p. 1240).

The diagnosis of chronic lead poisoning is of the utmost importance, but sometimes of great difficulty. The blue line upon the gums, if present, is practically pathognomonic, but its absence is of no negative value. Extensive degeneration of the blood corpuscles is also a symptom of great diagnostic importance, but may be absent in even severe cases. In doubtful cases a chemical examination of the urine for the presence of lead should be made. It must be remembered, however, that the presence of the metal does not prove that the case is one of lead poisoning; lead has been found in the urine of many persons in apparently normal health. As the elimination of lead through the kidneys is hastened by the administration of potassium iodide it is generally advisable to give

this salt two or three days before the collection of the sample for examination.

The treatment of chronic lead poisoning resolves itself into three divisions: to stop the ingestion of the poison, to hasten its elimination, and to relieve symptoms. The most important step in the first of these is to find the source. While in the majority of instances the disease is an occupational one, yet in some cases much ingenuity is required to trace its origin. It has been attributed in obscure cases to the use of various cosmetics containing lead, to lead-foil around chewing tobacco or confectionery, to biting of silk thread which has been weighted with lead, to the use of improperly glazed earthenware vessels, etc., but outside of workers in the metal it most commonly obtains entrance into the body with the drinking water. The daily use of magnesium sulphate serves the double purpose of keeping the bowels open and of precipitating any lead which may be eliminated into the intestinal tract. For the purpose of aiding in the excretion of the metal the most important single measure is the administration of potassium iodide which forms a soluble compound with the metal. The use of sweat baths containing sulphur has also been recommended.

Warm *sulphuretted baths* may be provided by dissolving four ounces of potassium sulphide in thirty gallons of water, in a wooden tub. These baths cause discoloration of the skin, from the formation of lead sulphide, and should be repeated every few days, until this effect ceases to be produced. After each bath the patient should be well washed with soap and water with the aid of a flesh brush, in order to remove the discoloration. By proceeding in this way, the lead on the skin, or in its pores, is rendered insoluble and inert, and at the same time removed.

The manifestations are so protean that it is impossible to consider here all the measures for relief of symptoms. For the colic the most generally useful drug is belladonna in full dose. If the pain is very severe morphine may be given which acts not only by its direct analgesic effect, but by relaxing the intestinal spasm.

We have seen life apparently saved in a violent attack of lead cerebritis by free venesection and the injection of physiological salt solution.

PODOPHYLLI INDICI RESINA. Br.

INDIAN PODOPHYLLUM RESIN [Podophyllum Emodi Resin]

(pŏd-o-phy'lī ĭn'dĭ-çī rĕ-sī'nă)

"Indian Podophyllum Resin is a powdered resin prepared by the same process as that described under 'Podophylli Resina,' employing Indian Podophyllum Rhizome in place of Podophyllum Rhizome. It possesses the characters and responds to the tests described under 'Podophylli Resina.'" *Br.*

(See *Podophylli Indici Rhizoma.*)

The rhizome of the Indian podophyllum has become a commercial article and appears to have been largely used in the making of podophyllin. The question as to the relative yield of the Indian and American plants is a matter of great importance to the manufacturer, it usually being stated that the Indian rhizome is twice as active. Some years since Dymock and Hooper obtained 12 per cent. of resin from *P. Emodi;* Umney, working with large quantities (*P. J.*, Sept., 1902), got out 11.4 per cent.; since then John Barclay (*P. J.*, 1903, lxx) was not able to obtain a greater yield than 6.69 per cent. Umney, commenting on this, believes that of late years the Indian plant gives a much smaller product than formerly, probably on account of the time of year in which it is now dug. In regard to the therapeutic interchangeability of the two resins it has been demonstrated by the researches of Dunstan and Henry and J. C. Umney that the active substances in true podophyllin are all present in the Indian resin, but it is not assured that the proportion of these active principles is the same in the two resins. At one time it was claimed that the resin from the Indian species was more active than that obtained from the American plant, but this appears not to be correct. In the present state of our knowledge, the manufacturer is certainly not justified in putting upon the market a resin made from the Indian plant unless it is plainly marked as the Indian podophyllin. Distinguishing between the two resins has become a question of importance. The presence of a yellowish-green color does not, as has been affirmed, prove that a podophyllin is impure or of Indian origin. The test of solubility is also uncertain. The Indian podophyllin, properly prepared, is freely soluble in alcohol. It is commonly stated that the true podophyllin will dissolve in ammonia (1 to 100). The Indian species is seemingly much less soluble in ammonia than this, but a properly prepared official resin does not always come up to this standard. E. J. Millard (*P. J.*, lx) states that the Indian resin strikes with strong sulphuric acid an orange to red color, the official resin yellow coloration, tending to brown, but especially commends the following test:

To six grains (0.4 Gm.) of the resin in a test tube add one fluidrachm (3.75 mils) of diluted alcohol sp. gr. 0.920, and eight or ten drops (0.4–0.5 mil) of solution potash, B. P.; shake gently by rotating the test tube. In case of the Indian resin, the mixture becomes in a few seconds a semi-solid gelatinous mass, so that the test tube can be safely inverted. If this does not occur quickly, the mixture should be heated until it just begins to boil, and when cold it will be found to have gelatinized. The official resin similarly treated gives a dark fluid that shows no signs of gelatinizing even after standing for days. The Indian Podophyllum Resin is used for the same purposes as the American. (See *Resina Podophylli.*)

Dose, one-fourth to one grain (0.016 to 0.065 mil); of the *tincture* (*Tinctura Podophylli Indici*), five to fifteen minims (0.3–0.9 mil).

PODOPHYLLI INDICI RHIZOMA. Br.

INDIAN PODOPHYLLUM RHIZOME [Podophyllum Emodi Rhizome]

(pŏd-o-phy̆l'lī ĭn'dĭ-çī rhī-zō'mą)

"Indian Podophyllum Rhizome is the dried rhizome and roots of Podophyllum Emodi, *Wall.*" *Br.*

Podophyllum Emodi (Fam. *Berberidaceæ*) is a perennial herb which is indigenous to Thibet and Afghanistan. It somewhat resembles our American Podophyllum. The stem rises to a height of six or twelve inches before the leaves, which attain a diameter of six to ten inches when fully expanded. The latter are curiously reflexed, droop umbrella-like and are often spotted. The plant produces in May a large sub-sessile pinkish-white flower which arises from the axil of one of the leaves, maturing before the latter are fully expanded. The fruit is about the size of a small lemon, of a bright orange color, being fully ripe in about August or September.

The contorted rhizome of *Podophyllum Emodi* is from six to eight mm. in thickness, crowded above with numerous buds or short branches, marked by depressed oval or circular scars, and giving off numerous simple rootlets from the whole of the under surface. The terminal bud is enclosed in whitish papery sheaths. The color is earthy-brown. The fracture is white, short, and mealy, or yellow and horny, exhibiting a circular arrangement of yellow vascular bundles, and bounded on the outside by a thin brown cortical layer.

"Rhizome cylindrical or flattened, contorted, earthy-brown; usually about ten millimetres thick; below with numerous root-scars, or with stout roots, and crowned with the short remains of aerial stems, bearing cup-shaped scars. In transverse section, pale-brown and starchy or horny, with a ring of radially elongated wood-bundles. Slight odor; taste bitter and acrid." *Br.*

It is used for the same purposes as podophyllum.

Off. Prep.—Podophylli Indici Resina, *Br.;* Tinctura Podophylli Indici (from Resin), *Br.*

PODOPHYLLUM. U. S. (Br.)

PODOPHYLLUM Podoph. [Mandrake, May Apple Rhizome]

(pŏd-o-phy̆l'lŭm)

"The dried rhizome and roots of *Podophyllum peltatum* Linné (Fam. *Berberidaceæ*), yielding not less than 3 per cent. of resin." *U. S.*
"Podophyllum Rhizome is the dried rhizome and roots of Podophyllum peltatum, *Linn.*" *Br.*

Podophylli Rhizoma, *Br.;* Podophyllum Root, Wild Mandrake, Devil's Apple, Umbrella Plant, Vegetable Calomel, *Mandrake,* American Mandrake, Wild Lemon, Ground Lemon, Hog Apple, Indian Apple, Raccoon Berry, Duck's Foot, Rhizome de Podophyllum, *Fr. Cod.;* Fussblattwurzel, *G.;* Podofillo, *It.;* Podofilo (Rizoma de), *Sp.*

Podophyllum peltatum (May-apple) is an indigenous herbaceous plant. The rhizome is perennial, creeping, usually several feet in length, about one-quarter of an inch thick, brown externally, smooth, jointed, and furnished with roots at the joints. The stem is about a foot high, erect, round, smooth. The basal leaves are centrally peltate, with six or seven wedge-shaped lobes, irregularly incised at their summits, yellowish-green on their upper surface, paler and slightly pubescent beneath. The flower-bearing stems bear from one to three similar leaves. The flower is nodding, and appears between two leaves at the apex of the stem or at the base of the upper leaf when three leaves are present. The calyx is composed of three oval, obtuse, concave, deciduous sepals. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong, yellow anthers, of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow color, diversified by round brownish spots. Two species of the genus Podophyllum are known as growing in China while *Podophyllum Emodi,* which inhabits the interior ranges of the Himalayas and is very abundant in Cashmere, is recognized in the Br.

The plant has been found on Mount Togakushi, in Japan, and is extensively diffused through the Eastern United States, growing luxuriantly in moist shady woods and in low marshy grounds from Canada to Minnesota and southward to Florida and Texas. It is propagated by its creeping rhizome, and is often found in large patches. The flowers appear about the end of May and the beginning of June, and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its color and shape, it is sometimes called *wild lemon.* The rhizome is the official portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

Properties.—The dried rhizome is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with roots of a similar but somewhat paler color. It was determined, by an experiment of Wm. Saunders, that these roots contain as much active matter as the rhizome itself. It is officially described as follows: "Rhizome horizontal, nearly cylindrical, jointed, compressed on the upper and lower surfaces, sometimes branched; in pieces from 3 to 20 cm. in length, the internodes from 2 to 9 mm. in diameter; externally dark brown, longitudinally wrinkled or nearly smooth with irregular, somewhat V-shaped scars of scale leaves,

nodes annulate, upper portion marked with large, circular, depressed stem-scars and sometimes with buds or stem-bases; at or near the nodes on the lower portion occur numerous root-scars or roots from 2 to 7 cm. in length and about 2 mm. in thickness; fracture short; internally, bark light brown, wood with small yellowish, vascular bundles, pith large and white; odor slight; taste sweetish, disagreeably bitter and acrid. Under the microscope, a transverse section of the rhizome of Podophyllum shows an outer layer of one or two rows of reddish-brown cells; parenchyma of cortex and pith with numerous single, spherical, polygonal, or 2- to 6-compound starch grains, or rosette aggregates of calcium oxalate; vascular bundles from 24 to 34, arranged in a circle between cortex and pith. The powder is light brown, with a pronounced and characteristic odor; starch grains numerous, spherical, polygonal or 2- to 6-compound, the individual grains from 0.003 to 0.015 mm. in diameter; calcium oxalate crystals few, in rosette aggregates from 0.05 to 0.08 mm. in diameter and occasionally in raphides from 0.03 to 0.09 mm. in length; tracheæ with simple pores or reticulate thickenings; fragments of starch-bearing parenchyma and reddish-brown cork cells. Podophyllum yields not more than 3 per cent. of ash.

"**Assay.**—Proceed as directed for the preparation of *Resina Podophylli* (see page 944), using 10 Gm. of Podophyllum in No. 60 powder. It shows not less than 3 per cent. of resin." *U. S.*

"Rhizome nearly cylindrical, of very variable length, usually about five millimetres thick; dark reddish-brown, smooth or only slightly wrinkled; enlarged at intervals of about five centimetres, the upper surface of each enlargement being marked by a depressed circular scar, below which, on the under surface, are rather stout, brittle, brown roots, or the scars corresponding to them. In transverse section, either nearly white and starchy, or pale yellowish-brown and horny. Characteristic odor; taste slightly bitter and acrid." *Br.*

The root in its aggregate state is nearly inodorous, but in powder has a sweetish not unpleasant odor. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. Both the decoction and the tincture are bitter, but alcohol is said to be the best solvent of the active matter. V. Podwyssotzki (*Ph. Z. R.*, Bd. xx, 777) announced the active principle to be solely a neutral crystalline principle, *picropodophyllin*. This principle is associated with an inactive resin-acid, *picropodophyllic acid*, and the combination of the two he named *podophyllotoxin*. Picropodophyllin is in colorless, silky, extremely delicate needles, very soluble in chloroform, readily soluble in 95 per cent. alcohol, but very slighty in 75 per cent. alcohol. It is soluble in ether, and crystallizes from a warm saturated solution on cooling. It is insoluble in water, turpentine, or benzin. Podophyllotoxin is a bitter, white, resinous powder, soluble in weak alcohol and hot water. It may be precipitated from its alcoholic solution by water in large quantity. (*P. J.*, 1882, 1011.) Podwyssotzki also obtained *podophylloquercetin*, the coloring principle, which is closely allied to quercetin and is the cause of the varying color of resin of podophyllum. His results have since been corrected and supplemented by R. Kürsten (*A. J. P.*, 1891, 485), who has obtained the several principles in a purer state. The results of Kürsten's investigation are as follows: The podophyllotoxin prepared by Podwyssotzki's method was not constant in composition, and its melting point varied from 100° to 125° C. (212°–257° F.); further, the podophyllic acid of that author is composed mainly of a crystallizable, active, but very impure substance.

Podophyllotoxin, $C_{22}H_{24}O_8$, is obtained by extracting the coarsely powdered rhizome with cold, light petroleum, until freed from fat; after drying in the air, the extraction is continued with chloroform, until the liquid comes away almost free from yellow color. As it is not possible to work with alcohol-free chloroform, too prolonged extraction with chloroform would yield a more impure extract. The chloroform extract is distilled and the residue is dried over a not too warm water bath, partially dissolved in benzene, filtered, and the filtrate allowed to remain from three to eight days, when a brownish-yellow mass of well-formed, thick, strongly refractive prisms is produced. This is purified by washing with a 50 per cent. alcohol, then with ether, recrystallizing first from boiling benzene, and finally from solution in hot 45 per cent. alcohol; the compound is thus obtained in long, well-formed prisms which melt at 94° C. (201.2° F.).

Podophyllotoxin, when oxidized in an alkaline solution in the cold by means of potassium permanganate, yielded, besides a little carbonic anhydride and a brown amorphous substance, principally two compounds, the more considerable of which was *podophyllic acid*, obtained as well-formed, colorless crystals from solution in a mixture of benzene and alcohol. The compound is without action on animals. It melts at from 158° to 160° C. (316.4°–320° F.). Its aqueous solution, neutralized with aqueous potassium hydroxide, gives no precipitate with gold, calcium, or barium chlorides; silver nitrate gives a white precipitate, soluble in much water; copper acetate gives a blue precipitate. The copper salt was prepared as beautiful light green prisms and analyzed.

Picropodophyllin results from the action of alkalies on podophyllotoxin; thus, on heating the latter with aqueous ammonia, a well-crystallized product is obtained, which at first was recrystallized from strong alcohol; but this was found to be unnecessary, as the melting point, 227° C. (440.6° F.), was not affected by it. Picropodophyllin has the same composition as podophyllotoxin, but they differ in melting point and in their action on polarized light,—the former inactive, the latter lævo-rotatory; the

former is less soluble in all liquids than the latter; the latter gives Millon's reaction, the former does not. By oxidation and reduction the two compounds yield the same products.

Dunstan and Henry (*Proc. Chem. Soc.*, March, 1898) find that the constituents of the Indian podophyllum (*Podophyllum Emodi*) and of the American podophyllum (*Podophyllum peltatum*) are identical. The chief constituent is the *podophyllotoxin* of Podwyssotzki and Kürsten. It is strongly lævorotatory, and acts as a powerful purgative and intestinal irritant. They found that when heated with alkalies, it is converted by hydration into the salt of an unstable gelatinous acid, *podophyllic acid*, $C_{15}H_{16}O_7$, of which several salts were obtained and analyzed. This acid very readily loses water, and furnishes the crystalline *picropodophyllin* of Podwyssotzki and Kürsten, which is isomeric with podophyllotoxin. It passes again into podophyllic acid when warmed with aqueous alkalies. Podophyllotoxin and picropodophyllin furnish identical decomposition products; when oxidized with nitric acid, oxalic acid is the principal product; when fused with alkalies, *orcinol* and acetic acid are produced. Both substances contain three methyl groups and no hydroxyl. It is likely that picropodophyllin is the lactone of podophyllic acid. Picropodophyllin is therapeutically inactive. The yellow coloring matter of podophyllum, called by Podwyssotzki *podophylloquercetin*, was proved by the authors to be identical with quercetin, the yellow coloring matter of quercitron bark. An uncrystallizable resin, *podophylloresin*, was also isolated and found to exert a purgative action. A fatty oil has been separated from the rhizome of podophyllum by Dohme and Engelhardt. (See *Proc. A. Ph. A.*, 1904, 340.) Gordin and Merrell (*Proc. A. Ph. A.*, 1902, 343) proposes to judge of the quality of resin of podophyllum by an assay based on the percentage of crude picropodophyllin and the following requirements: 1. Pure podophyllin must be completely soluble in about twice its weight of cold alcohol. 2. It should contain about 64 per cent. ether-soluble and about 74 per cent. chloroform-soluble matter. 3. It should yield about 22 per cent. crude picropodophyllin when assayed by the method described by them.

Manlius Smith recommended that the resin should be prepared by forming an alcoholic tincture of the root, evaporating the tincture until most of the alcohol is driven off, and throwing the residue into water, by which the resin is precipitated. The concentration should not be carried too far, as otherwise the resin separates in clots, which cannot be easily washed. According to Smith, the resin, when pure, is white, and purges actively. It has been called *podophyllin* for many years. (*A. J. P.*, xxiv. 306. See *Resina Podophylli.*) The proportion of resin contained in the root of the *P. peltatum* appears to vary very much, the variation possibly depending upon the season of the year at which the drug has been gathered. John Barclay (*P. J.*, 1903, Feb., 164) obtained a percentage of 1.6 to 3.86 per cent., stating that these figures were confirmed by the results of the manufacturers of podophyllin on a large scale, but J. C. Umney states that in five years' experience working with batches of 1000 pounds, the rhizome averaged a yield of 6.6 per cent. Both observers noticed that the Indian rhizome (*P. Emodi*) contains a much larger proportion of resin, the average according to Umney being 11.4 per cent. How far the proportion of podophyllotoxin varies in the different rhizomes does not seem to have been determined. (See B. D. Dott, *P. J.*, 1903, Mar. 460.) (*P. J.*, 1911, lxxxvii, p. 156.)

From the *leaves* of *P. peltatum* Thos. J. Husband, Jr., obtained berberine and a resin which was free from purgative properties, 8 grains producing no other effect than slight headache. (*A. J. P.*, 1869.)

B. F. Carter (*A. J. P.*, 1886, p. 449) also examined the leaves. He found tannin, uncrystallized sugar, coloring matter, and 6 per cent. of resin. This latter seems to be of twofold character, ether dissolving the soft resin, while the hard resin remains behind. The resin has a bitter taste and a much milder action than that of the rhizome. Fused with potassium hydroxide a small amount of protocatechuic acid seems to be formed.

A method of assay for Podophyllum has been proposed by W. M. Jenkins (*J. I. and E. C.*, 1914, p. 671) which is based upon a shaking out method using a mixture of chloroform and alcohol.

Uses.—Podophyllum is a slow but active and certain cathartic producing copious liquid discharges often with much griping. It has been attributed with cholagogic properties and is used in various forms of *hepatic torpor* but its virtues in this direction are probably no greater than that of other active purgatives. In small doses it is frequently used in *chronic constipation*, especially in conjunction with aloes or cascara.

In overdoses podophyllum acts as an irritant poison; an amount estimated at five grains of the resin caused death in a woman sixty years old (*N. Y. M. R.*, April, 1890); the symptoms were vomiting and purging, followed some hours after their cessation by coma, full soft pulse, slight elevation of temperature, and hæmoglobinuria.

Dose, five to ten grains (0.32–0.65 Gm.), but it is rarely exhibited in the crude form.

POTASSA SULPHURATA. U. S., Br.

SULPHURATED POTASSA Pot. Sulphurat.
[Liver of Sulphur]

(pŏ-tăs'są sŭl-phū-rā'tą)

"A mixture composed chiefly of potassium polysulphides and potassium thiosulphate and containing an amount of sulphides corresponding to not less than 12.8 per cent. of sulphur (S). Preserve it in well-closed containers." *U. S.* "Sulphurated Potash is a mixture of salts of potassium, chiefly sulphides." *Br.*

Sulphurated Potash, *Br.*, Hepar Sulphuris; Potassii Sulphuretum, *U. S.* 1870; Sulphuret of Potassium, Sulphurated Potash; Sulfure (tri) de Potassium solide, *Fr. Cod.*; Sulfure de Potasse, Foie de Soufre, *Fr.*; Kalium Sulfuratum, *P. G.*; Schwefelleber, Kalischwefelleber, *G.*; Sulfuro (tri) potasico hiposulfitado, *Sp.*

"Potassiuum Carbonate, in powder, 100 *grammes;* Sublimed Sulphur, 50 *grammes.* Mix the Potassium Carbonate, previously dried, with the Sulphur; heat in a covered crucible, at first gently, afterwards to dull redness, until effervescence ceases and the mass fuses; pour it on to a clean stone slab, and, after solidification, break it into fragments and transfer to a stoppered bottle." *Br.*

The U. S. P. IX gives no process; that of the U. S. P., 1890, is as follows: "Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Potassium Carbonate, dried, *two hundred grammes* [or 7 ounces av., 24 grains]. Mix the powdered and dried Potassium Carbonate thoroughly with the Sublimed Sulphur, and gradually heat the mixture, in a covered crucible, which should be only about half filled with it, until the mass ceases to foam and is in a state of perfect fusion. Then pour the fused mass on a cold marble slab, and, after it has cooled, break it into pieces, and keep it in a well-stoppered bottle."

These processes are essentially the same, except that a greater heat is used in the British process, which somewhat modifies the result. When potassium carbonate is melted with half its weight of sulphur, as in the U. S. P. 1890 process, the carbon dioxide is expelled. The composition varies with the heat employed. If the heat does not exceed 185° C. (365° F.), the resulting preparation will contain potassium thiosulphate; if above 300° C. (572° F.), potassium sulphate. (Fordos and Gélis.) The reaction for the preparation at the lower temperature is

$$3K_2CO_3 + 4S_2 = 2K_2S_3 + K_2S_2O_3 + 3CO_2$$

which at the higher temperature is changed as follows:

$$4K_2S_2O_3 = 3K_2SO_4 + K_2S_5$$

The potassium pentasulphide formed is decomposed at this high temperature into sulphur, which burns off, and K_2S_3. The U. S. preparation, therefore, which is made at the temperature of fusion, probably contains potassium thiosulphate, and may be represented by the formula $2K_2S_3 + K_2S_2O_3$, three molecules of CO_2 escaping, while the British, being prepared at a red heat, contains potassium sulphate, the reaction probably being

$$4K_2CO_3 + 5S_2 = K_2SO_4 + 3K_2S_3 + 4CO_2$$

Potassium carbonate from pearlash is usually employed by the manufacturer, but in the process of Henry, which is stated to be the best yet devised, the pure potassium carbonate is employed. His formula is as follows: Mix two parts of pure potassium carbonate with one of sulphur reduced to powder, and put the mixture into flat-bottomed flasks, which should be only two-thirds filled. These are placed on a sand bath, and the fire is applied so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the flasks do not become obstructed. The heat is continued until the matter is brought to a state of tranquil fusion, when it is allowed to cool. The mass obtained, which is compact, smooth, and of a fine yellow color, is broken into pieces, and preserved in well-stoppered bottles. W. Elborne (*Y. B. P.*, 1896, 331) states that when commercial potassium carbonate is used in making sulphurated potassa, a product is obtained which more closely approaches the official compound (Br. Pharm. 1885) than does one made from a pure potassium carbonate. He recommends that dried commercial carbonate containing not less than 90 per cent. K_2CO_3 be employed.

Properties.—Sulphurated potassa, when properly prepared, is a hard, brittle substance, having a nauseous, alkaline, and bitter taste. Its color is liver-brown, and hence its name of *hepar sulphuris,* or *liver of sulphur.* The color of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid odor when moist, owing to the extrication of a little hydrogen sulphide gas. It is soluble in water, forming an orange-yellow liquid, and exhaling the odor of hydrogen sulphide. It is described in the U. S. P. IX as follows: "Sulphurated Potassa is in the form of irregular pieces, liver-brown when freshly made, changing to greenish-yellow and finally to gray through absorption of moisture, oxygen, and carbon dioxide from the air. It has a strong odor of hydrogen sulphide and a bitter, acrid, and alkaline taste. Sulphurated Potassa is very soluble in water, usually leaving a slight residue. Alcohol dissolves only the sulphides. An aqueous solution of Sulphurated Potassa (1 in 10) is light brown in color and is strongly alkaline to litmus. The addition of an excess of acetic acid to this solution causes a brisk evolution of hydrogen sulphide and a precipitation of sulphur. In the liquid thus treated, after filtration, an excess of sodium bitartrate T.S. produces an abundant, white crystalline precipitate on standing.

"Assay.—Add a solution of 1 Gm. of crystallized copper sulphate in 15 mils of distilled water to a solution of 1 Gm. of Sulphurated

Potassa in 10 mils of distilled water, shake the mixture in a stoppered vessel for a few minutes and filter. The filtrate, acidulated with acetic acid and filtered if necessary, produces no black precipitate with an equal volume of hydrogen sulphide T.S., corresponding to not less than 12.8 per cent. of sulphur combined as sulphides." *U. S.*

"Solid fragments, externally greenish-yellow, internally pale liver-brown, rapidly changing to greenish-yellow on exposure to the air. Odor that of hydrogen sulphide; taste alkaline and acrid. Readily soluble in *water*. Aqueous solution yellowish, opalescent; deposits only a trace of sediment on standing; evolves hydrogen sulphide freely on the addition of excess of *hydrochloric acid*, sulphur being deposited; this acid liquid, boiled and filtered, gives a yellow precipitate with *solution of platinic chloride*. Sulphurated Potash contains not less than 42 and not more than 45 per cent. of sulphur as determined by the following process:—Dissolve 0.2 gramme in 10 millilitres of *water* in a small flask, add 5 millilitres of *solution of sodium hydroxide*, heat the liquid to boiling, and add slowly, the flask being constantly rotated, *solution of bromine As T.* until a clear solution is obtained and bromine is present in excess. Acidify with *hydrochloric acid*, boil until the excess of bromine is driven off, add excess of *solution of barium chloride*, collect the precipitate formed, wash, dry, ignite, and weigh. It weighs not less than 0.611 or more than 0.655 gramme." *Br.*

By exposure to the air it attracts oxygen, and the potassium sulphide is gradually changed into potassium sulphate, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which liberate hydrogen sulphide and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphides. When boiled with an excess of hydrochloric acid and filtered, it gives a yellow precipitate with platinic chloride, and a white one with barium chloride. The preparation of the Br. Pharmacopœia yields about one-half of its weight to alcohol (90 per cent.)—the portion dissolved being potassium sulphide, and the undissolved portion potassium sulphate.

This compound has been used as an ingredient in the preparation known as *Lotio Alba* (*Lotio Sulphurata*) of which the following is the correct formula, according to Otto Raubenheimer (*J. A. Ph. A.*, 1914, 692): Zinc sulphate, 5 Gm.; sulphurated potassa, 5 Gm.; distilled water, q.s. to make 125 mils. Dissolve each chemical in 60 mils of distilled water; filter the solutions separately and mix by slowly pouring the potassa solution into the zinc solution, then add sufficient distilled water to make 125 mils. Rose water may be used in place of distilled water. It is essential that the sulphurated potassa be fresh and free from iron compounds, as has been pointed out by J. C. and B. L. DeG. Peacock, *Proc. P. P. A.*, 1914, 256.

Uses.—Internally sulphurated potassa was formerly employed in *chronic rheumatism, skin diseases, asthma*, etc., but is to-day rarely used as an internal remedy. While if given in sufficient dose it may exercise the same effects upon the system as sulphur it is much more irritant to the stomach and has no advantages. It is, however, a valuable external agent in the treatment of various skin diseases. The alkaline sulphides exercise a solvent action upon the horny element of the skin and therefore sulphurated potassa is useful in *psoriasis* and other conditions in which there is excessive formation of scales. Because of the anti-parasitic action of the hydrogen sulphide which it liberates on contact with the skin, it is one of our most valuable remedies in the treatment of *scabies, ring-worm, tinea versicolor*, and other parasitic diseases. In *acne rosaceæ* and other skin diseases with sluggish circulation its local stimulating action tends to restore tone to the dilated blood vessel. It may be used either as a lotion, an ointment, or bath. As a lotion it is usually used in strengths of about 5 per cent. but in sluggish conditions may be employed up to 10 per cent. For an ointment one-half a drachm of sulphurated potassa (2 Gm.) may be rubbed up with one-half an ounce (15 Gm.) of lard. For a bath about one-half a drachm is employed for each gallon of water. The odor of sulphurated potassa is favorably modified whether in solution or ointment, by incorporating with it a little oil of anise.

Dose, from two to ten grains (0.13–0.65 Gm.).

POTASSII ACETAS. U. S., Br.

POTASSIUM ACETATE Pot. Acet

(pŏ-tăs'sĭ-ī ă'cē-tăs)

"It contains, when dried to constant weight at 150° C. (302° F.), not less than 99 per cent. of $KC_2H_3O_2$ (98.12). Preserve it in air-tight containers." *U. S.* "Potassium Acetate may be obtained by fusing the product of the interaction of acetic acid and potassium carbonate. It contains not less than 90 per cent. of pure potassium acetate, $KC_2H_3O_2$." *Br.*

Kali Aceticum, Sal Diureticum, Acetas Potassicus, s. Kalicus, Terra Foliata Tartari; Acetate of Potassium; Acetate of Potash (Potassa), Diuretic Salt; Acétate de Potasse sec, *Fr. Cod.*; Essigsaures Kali, *G.*; Acetato di potassio, *It.*; Acetato potasico, *Sp.*

As this salt is practically never prepared on a small scale, no process is given in either of the Pharmacopœias; that of the U. S. P., 1870, is as follows: "Take of Acetic Acid *a pint;* Bicarbonate of Potassium *a sufficient quantity*. Add the Bicarbonate gradually to the Acid until it is neutralized; then filter the solution, and evaporate cautiously, by means of a sand-bath, until a dry salt remains."

For drying the potassium acetate, Christison considers the temperature of a vapor bath too low, and that of a sand bath likely to become too high. He therefore recommends the use of a bath of calcium chloride when operating on a small scale. In conducting the evaporation, it

is best to have the solution always slightly acid, for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration. On account of the liability of discoloration, great care must be observed to avoid the contamination of iron. Some manufacturers use silver dishes.

Potassium acetate may also be obtained by double decomposition between lead acetate and potassium sulphate. When thus procured, it is very white and pure, but liable to the objection, for medicinal use, that it may possibly contain a little lead. Another method by double decomposition is between calcium acetate and potassium sulphate.

Properties.—It is officially described as "a white powder, or in crystalline masses of a satin-like luster; odorless, or with a faint, acetous odor, and having a warming, saline taste. It is very deliquescent on exposure to the air. One Gm. of Potassium Acetate dissolves in 0.5 mil of water and in 2.9 mils of alcohol at 25° C. (77° F.); also in about 0.2 mil of boiling water. An aqueous solution of the salt (1 in 20) is alkaline to litmus, but does not affect phenolphthalein T.S. When slightly heated, the salt fuses. On strong ignition it is decomposed with the evolution of inflammable empyreumatic vapors and leaves a black residue of potassium carbonate and carbon. This residue imparts to a non-luminous flame a violet color, is alkaline to litmus, and effervesces with acids. The addition of 5 mils of sodium bitartrate T.S. to 5 mils of an aqueous solution of the salt (1 in 5) causes a white, crystalline precipitate. Add 0.1 Gm. of the salt to 1 mil of sulphuric acid and 1 mil of alcohol and gently warm the mixture; ethyl acetate is formed, recognizable by its odor. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Dry the salt to constant weight at 150° C. (302° F.) and proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows, in the dried salt, not less than 99 per cent. of $KC_2H_3O_2$. Each mil of half-normal sulphuric acid V.S. used corresponds to 0.04906 Gm. of $KC_2H_3O_2$. Each gramme of Potassium Acetate, previously dried, corresponds to not less than 20.2 mils of half-normal sulphuric acid V.S." *U. S.*

"White foliaceous satiny masses, or in granules. Taste sharp, saline. Very deliquescent. Soluble in 0.5 part of *water*, and in 2 parts of *alcohol* (90 per cent.). Aqueous solution alkaline to *litmus*. Yields the *reactions* characteristic of potassium and of acetates. Yields no characteristic *reactions* for copper, iron, aluminum, calcium, magnesium, carbonates, or sulphides, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Loses not more than 10 per cent. of its weight when dried at 100° C. (212° F.). 1 gramme, heated to redness until gases cease to be evolved, leaves an alkaline residue which, when treated with *water*, filtered, and well washed, yields a clear solution requiring for neutralisation not less than 18.3 millilitres of *N/2 solution of sulphuric acid.*" *Br.*

Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subjected to adulteration. Potassium acetate is incompatible with the mineral acids, which expel the acetic acid; with sodium and magnesium sulphates; with corrosive sublimate and silver nitrate, and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees, and is the principal source of the potassium carbonate existing in the ashes of wood.

Uses.—The effects of potassium acetate upon the system are very similar to those of the citrate (see page 897), except that it is less likely to act upon the bowels. Like the citrate it is oxidized in the system and appears in the urine as a carbonate and therefore tends to render this secretion alkaline. It is usually less acceptable to the palate than the citrate. It is especially employed in the treatment of *rheumatic fever* and the *uric acid diatheses*. It is also sometimes used for its diuretic effect in *dropsies* and *nephritis*. J. A. Easton, of Glasgow, has found it useful in several skin diseases, such as *psoriasis* and *eczema*.

Dose, fifteen to sixty grains (1–3.9 Gm.).

Off. Prep.—Elixir Buchu et Potassii Acetatis, *N. F.*; Elixir Potassii Acetatis, *N. F.*; Elixir Potassii Acetatis et Juniperi, *N. F.*

POTASSII BICARBONAS. U. S., Br.

POTASSIUM BICARBONATE Pot. Bicarb.

(pŏ-tăs'sĭ-ĭ bī-căr'bŏ-năs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of $KHCO_3$ (100.11). Preserve it in well-closed containers." *U. S.* "Potassium Bicarbonate may be obtained by saturating a strong aqueous solution of potassium carbonate with carbon dioxide. It contains not less than 99 per cent. of pure potassium bicarbonate, $KHCO_3$." *Br.*

Bicarbonas Potassicus, s. Kalicus; Potassium Hydrogen Carbonate; Acid Carbonate of Potassium; Bicarbonate of Potash; Carbonate (bi) de Potasse, *Fr. Cod.*; Bicarbonate de Potasse, *Fr.*; Kalium Bicarbonicum, *P. G.*; Kaliumbicarbonat, Doppelt-Kohlensaures Kali, *G.*; Bicarbonato di potassio, *It.*; Bicarbonato potasico, *Sp.*

The process of the U. S. P. 1870, and also that of the British Pharmacopœia, for this salt were abandoned at former revisions.

The reaction by which it is produced from potassium carbonate by the action of carbon dioxide is as follows:

$$K_2CO_3 + H_2O + CO_2 = 2KHCO_3$$

Brande gives the following proportions for the preparation of potassium bicarbonate: "100 lbs. of purified potassium carbonate are dissolved in 17 gallons of water [Imperial meas-

ure], which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallized bicarbonate; 50 lbs. of potassium carbonate are then added to the mother-liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated." Wöhler states that charcoal, when mixed with the carbonate, facilitates by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus, he found that, when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbon dioxide, the gas was absorbed with great rapidity, and heated the mass so considerably as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of water at the temperature of from 29.4° to 37.7° C. (85°–100° F.), and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (See *A. J. P.*, x, 82.)

Behrens has proposed to obtain potassium bicarbonate by partially saturating the carbonate, dissolved in an equal weight of water, with acetic acid gradually added. Up to a certain point, no carbon dioxide is extricated, and a precipitate takes place of pure potassium bicarbonate, equal to half the weight of the carbonate employed. After the bicarbonate is separated, the saturation may be completed, and potassium acetate obtained. (*J. P. C.*, 3e sér., iv, 464.) L. Pesci dissolves purified potassium hydroxide in 80 per cent. alcohol, and passes a stream of carbon dioxide through the solution until it is saturated. The white precipitate is collected and washed with alcohol; it is free from chlorides and nitrates. (*Ber. d. Chem. Ges.*, 1876.)

According to Berzelius, the cheapest method of obtaining potassium bicarbonate is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask, over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbon dioxide, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers may prepare this salt with great facility by suspending the alkaline solution in the fermenting tun. The salt in powder called *potash sal aëratus*, made principally in New England, is prepared in this way. In composition it is between a carbonate and a bicarbonate and it is sometimes called a sesquicarbonate.

Properties.—Potassium bicarbonate is officially described as in "colorless, transparent, monoclinic prisms or as a white, granular powder, odorless, and having a saline and slightly alkaline taste. It is permanent in the air. One Gm. of Potassium Bicarbonate dissolves in 2.8 mils of water at 25° C. (77° F.); also in 2 mils of water at 50° C. (122° F.); almost insoluble in alcohol. An aqueous solution of Potassium Bicarbonate (1 in 10) is slightly alkaline to litmus but is neutral or slightly alkaline to phenolphthalein T.S., and effervesces with acids. When heated above 50° C. (122° F.) an aqueous solution of the salt rapidly loses carbon dioxide and water, and, at boiling heat, the salt is entirely converted into normal carbonate. The dry salt begins to lose carbon dioxide and water at 100° C. (212° F.) and this loss increases at a higher temperature, until at a red heat a residue of carbonate remains which imparts a violet color to a non-luminous flame. An aqueous solution of Potassium Bicarbonate (1 in 10) yields a white, crystalline precipitate of potassium bitartrate with excess of tartaric acid T.S. Add 2 mils of tenth-normal hydrochloric acid V.S. and 2 drops of phenolphthalein T.S. to 1 Gm. of the salt, dissolved without agitation in 20 mils of distilled water at a temperature not above 15° C. (59° F.); a red tint does not appear immediately (*carbonate*). An aqueous solution of the salt (1 in 50), mixed with a slight excess of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve about 4 Gm. of Potassium Bicarbonate, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 25 mils of distilled water and titrate with normal sulphuric acid V.S., methyl orange T.S. being used as indicator. It shows, in the dried salt not less than 99 per cent. of $KHCO_3$.

"Each mil of normal sulphuric acid V.S. used corresponds to 0.10011 Gm. of $KHCO_3$. Each gramme of Potassium Bicarbonate, previously dried, corresponds to not less than 9.9 mils of normal sulphuric acid V.S." *U. S.*

"Colorless, monoclinic, non-deliquescent prisms. Taste saline, feebly alkaline. Soluble in 4 parts of *water*, almost insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of bicarbonates. 1 gramme exposed to a low red heat leaves not less than 0.683 or more than 0.690 gramme of a white residue, which requires for neutralisation not less than 19.8 or more than 20 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, sulphates, or sodium, and not more than the slightest *reactions* for iron or chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million. 20 grammes of Potassium Bicarbonate are neutralised by 14 grammes of Citric Acid, and by 15 grammes of Tartaric Acid." *Br.*

When heated to redness it loses carbon dioxide and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method was adopted in the U. S. Pharmacopœia of 1870 for obtaining the pure carbonate. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of magnesium sulphate. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Christison, no precipitate will be occasioned even when 50 per cent. of this impurity is present. Potassium bicar-

bonate does not decompose calomel. When dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate; but if it contain so much as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (Christison.) Another way of detecting the presence of carbonate is to add pure glucose to a heated solution of the suspected bicarbonate. If any carbonate be present, the mixture will turn yellow or brown. (Chevallier.) The official test (Hirsch's) given above is, however, more reliable, and admits but traces of carbonate. Potassium bicarbonate consists of one atom of potassium and one of hydrogen, in combination with one carbonic acid group, CO_3.

Uses.—The medicinal properties of this salt are similar to those of the carbonate, to which it is preferable from its milder taste and its greater acceptability to the stomach. It is, however, much more disagreeable than the salts of potassium made from the fruit acids which are now universally used when a decided effect upon the system is desired, the bicarbonate and the carbonate being employed almost exclusively as gastric antacids.

Dose, ten grains to a drachm (0.65–3.9 Gm.).

POTASSII BICHROMAS. Br.

POTASSIUM BICHROMATE [Potassii Dichromas, U. S. 1890, Potassium Dichromate]

(pŏ-tăs'sĭ-ī bī-ĉhrō'măs)

"Potassium Bichromate may be obtained by roasting chrome ironstone with lime in the presence of air, and treating the resulting chromate with a potassium salt, and subsequently with an acid. It contains not less than 99 per cent. of pure potassium bichromate, $K_2Cr_2O_7$." *Br.*

Red Chromate of Potash (Potassa), Bichromate of Potash; Kali Bichromicum, Kali Chromicum Rubrum; Chromate (Bi) de Potasse, *Fr. Cod.;* Bichromate de Potasse, *Fr.;* Kalium dichromicum, *P. G.;* Kaliumdichromat, Zweifach Chromsaures Kali, Doppeltchromsaures Kali, *G.;* Bicromato di potassio, *It.;* Bicromato potasico, *Sp.*

Potassium dichromate was deleted from the U. S. P. IX list, but will be found among the reagents under *Potassium Dichromate, Purified.* (See Part III.)

This salt is most conveniently prepared from the neutral or yellow *potassium chromate,* by acidulating its solution with sulphuric acid and setting it aside for a day or two. In the action which follows we may suppose two reactions take place:

$$2K_2CrO_4 + H_2SO_4 = K_2SO_4 + 2KHCrO_4$$
$$2KHCrO_4 = K_2Cr_2O_7 + H_2O$$

Here the sulphuric acid, taking half the base from the two molecules of neutral chromate, changes them into two molecules of an acid chromate. This, however, is unstable, and the two molecules condense to form one of the dichromate with the elimination of one molecule of water. The yellow chromate is obtained by igniting four parts of powdered chrome-iron ore with one part of potassium nitrate, and lixiviating the resulting mass with water, or it may be produced by heating the chrome iron ore in a reverberatory furnace with access of air in the presence of potassium carbonate and lime. This reaction is as follows:

$$2FeOCr_2O_3 + 4K_2CO_3 + 4CaO + 7O = Fe_2O_3 + 4CaCO_3 + 4K_2CrO_4$$

The solution, by evaporation, yields the yellow salt in crystals. In this process, the nitric acid of the potassium nitrate furnishes oxygen to convert the chromium sesquioxide into chromium trioxide, which then unites with the potassium of the same salt. The iron, in the mean time, is sesquioxidized and rendered insoluble. Sometimes impure potassium carbonate (pearlash) is substituted for part of the potassium nitrate in the calcination. Omitting the potassium nitrate entirely, Stromeyer, of Norway, in performing the ignition, has used lime along with the pearlash, with economical results. When lime is employed, calcium chromate is formed, which is extracted by lixiviation and decomposed by a soluble potassium salt, such as sulphate or carbonate, either of which will carry the lime out of solution. When desired, the dichromate may be obtained directly from the solution of potassium chromate, derived from the treatment of the ore by acidulating it with sulphuric acid, without first crystallizing it. The production of chrome ore in the United States has practically ceased, as the California deposits are no longer worked. The manufacture of potassium and sodium dichromates is therefore carried on with imported ore brought chiefly from Asia Minor and New Caledonia.

Properties.—Potassium dichromate, according to the U. S. P. VIII, is in "large, orange-red, transparent, triclinic prisms, or four-sided tabular crystals, odorless, and having an acidulous, metallic taste. Permanent in the air. Soluble in about 9 parts of water at 25° C. (77° F.), and in 1.5 parts of boiling water; insoluble in alcohol. The salt fuses below a red heat, without loss of weight, forming a dark brown liquid. At a white heat it evolves oxygen and leaves a residue of neutral potassium chromate and green chromic oxide. The aqueous solution of Potassium Dichromate (1 in 20) has an acid reaction upon blue litmus paper. On mixing 4 Cc. of an aqueous solution (1 in 20) with 0.5 Cc. of alcohol, and then adding 1 Cc. of sulphuric acid, the liquid should assume a green color and emit the odor of aldehyde. Sodium cobaltic nitrite T.S. produces in an aqueous solution a copious yellow precipitate."

"In orange-red crystals. Soluble in 10 parts of *water.* Aqueous solution acid to *litmus;* gives a yellowish-white precipitate with *solution of barium chloride;* acquires an emerald-green color when warmed with *sulphuric acid* and *alcohol* (90 per cent.). When 0.1 gramme is dissolved in 20 millilitres of *water* acidified with 5 millilitres of *diluted sulphuric acid,* and then 2 grammes of *potassium iodide* added, the solu-

tion thus obtained, diluted with *water*, requires for decolorisation not less than 20.1 millilitres of *N/10 solution of sodium thiosulphate* (presence of not less than 99 per cent. of pure potassium bichromate, $K_2Cr_2O_7$)." *Br.*

The oxidizing action of potassium dichromate which is so especially marked in the presence of free sulphuric acid may be understood by the following reaction in which it will be seen that each molecule of the bichromate yields 3 atoms of nascent oxygen and a molecule of chrome alum.

$$K_2Cr_2O_7 + 4H_2SO_4 = 4H_2O + Cr_2(SO_4)_3.K_2SO_4 + 3O$$

Uses.—Potassium dichromate is an irritant caustic acting much like chromium trioxide *q. v.* It was used by Robin, in 1850, in the treatment of *syphilis*, but was entirely abandoned. Its use, has, however, been recently revived in this disease by Helbig. (*Aerzt. Runds.*, 1910, p. 157.) He administers one-sixth of a grain (0.01 Gm.) well diluted three times a day. Fenwick (*B. M. J.*, 1909) recommends in *cancer* the injection of eight to fifteen minims (0.5–0.9 mil) of a 10 per cent. solution into the tumor, and Gemmil (*B. M. J.*, 1909) has had good results from its local application in *rodent ulcer*.

In overdoses it operates as a violent irritative and corrosive poison, producing severe vomiting, frequent dark hemorrhagic dejections, violent abdominal pains, pronounced disturbances of the circulation, coma, heart failure, collapse, etc. Less than an ounce has caused unconsciousness in five minutes, with death thirty-five minutes later. (*B. M. J.*, ii, 1888.) Soap, an alkaline carbonate, or magnesia, is the antidote. Potassium dichromate is used largely in calico printing and for other technical purposes. The workmen engaged in making it are liable to painful ulcerations of the hands, and, in consequence of the acrid vapors evolved, violent irritation of the nostrils is apt to be experienced, with severe pricking sensations and excessive sneezing, followed in time by destruction of the mucous membrane and even of the septum itself. It is asserted that this result may be avoided by breathing through the mouth exclusively, the profuse secretion of saliva produced carrying off the poisonous particles. (*B. F. M. R.*, Oct., 1863.)

Mueller's Fluid is used for preserving anatomical specimens. It consists of from 2 to 2.5 parts of potassium dichromate, 1 part of sodium sulphate, and 100 parts of water.

Dose, one-fifth of a grain (0.012 Gm.).

POTASSII BITARTRAS. U. S. (Br.)

POTASSIUM BITARTRATE Pot. Bitart.
[Cream of Tartar]

(pŏ-tăs'sĭ-ī bī-tär'trăs)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99.5 per cent. of $KHC_4H_4O_6$ (188.14). Preserve it in well-closed containers." *U. S.* "Acid Potassium Tartrate may be obtained from the crude cream of tartar deposited during the fermentation of grape juice. It contains not less than 99 per cent. of pure potassium hydrogen tartrate, $KHC_4H_4O_6$." *Br.*

Potassii Tartras Acidus, *Br.*, Acid Potassium Tartrate, Crystals of Tartar; Purified Cream of Tartar; Tartrate de Potasse acide, Bitartrate de Potasse, Crème de Tartre, *Fr. Cod.*; Pierre de Vin, *Fr.*; Tartras depuratus, *P. G.*; Weinstein, Kali Bitartaricum, Bitartras Potassicus, s. Kalicus, Cremor Tartari, *G.*; Tartrato acido di potassio, Cremor di tartaro, *It.*; Tartrato (bi)potasico, Cremor de tartaro, *Sp.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited in the casks, forming a crystalline crust, called *crude tartar*, or *argol*. That deposited from red wines is of a reddish color, and called *red tartar*, while that derived from white wines is of a dirty-white color, and denominated *white tartar*. Both kinds consist of potassium, united with an excess of tartaric acid, forming acid potassium tartrate, rendered impure by calcium tartrate, more or less coloring matter, and other substances which are deposited during the clarification of the wine. The deposition of the tartar is thus explained. The acid tartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is gradually replaced by alcohol, in which the salt is insoluble. It is from argol that acid potassium tartrate is obtained by a process of purification. The importation of crude tartar, or argol, for the year 1914 was 29,793,011 lbs., valued at $3,228,674, and for 1915, 28,624,554 lbs., valued at $3,094,380. Although the amount of crude tartar produced in the United States is small, compared with the quantity imported from Europe, yet the amount from American wines is rapidly increasing. The process for purifying crude tartar is founded upon the greater solubility of acid potassium tartrate in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposits on cooling a crystalline layer, nearly free from color. This is redissolved in boiling water, and the solution, having been mixed with 4 or 5 per cent. of pipe clay, or egg albumin and animal charcoal, is evaporated until a pellicle forms. The clay precipitates with the coloring matter, and the clear solution, as it cools, deposits white crystals in crusts, which, upon being exposed to the air on linen for several days, acquire an increased degree of whiteness. These constitute the *crystals of tartar* of pharmacy. The salt, as met with in commerce, is generally, for greater convenience, in the form of powder, to which the name *cream of tartar* properly belongs. (See *Bull. Pharm.*, 1898, 405.) A more recent process is that of roasting the crude argols at a temperature (150° C. (302° F.)) which will decompose albumin and organic coloring matter, but not affect the cream of tartar. The roasted product is divided and treated with a small amount of hydrochloric

acid, which attacks the calcium tartrate and as cream of tartar is almost insoluble in the KCl formed a relatively pure potassium bitartrate separates out.

Properties.—Potassium bitartrate occurs in commerce in white crystalline crusts or masses of aggregated crystals, which are usually powdered before being sold to pharmacists. It is officially described as in "colorless or slightly opaque, rhombic crystals, or as a white, somewhat gritty powder; odorless, and having a pleasant, acidulous taste. It is permanent in the air. One Gm. of Potassium Bitartrate dissolves in 155 mils of water and in 8820 mils of alcohol at 25° C. (77° F.); also in 16 mils of boiling water. A saturated aqueous solution of the salt is acid to litmus. When the salt is heated it chars and emits inflammable vapors having the odor of burning sugar. At a higher temperature, with free access of air, the carbon of the black residue is consumed, and a white, fused mass of potassium carbonate remains, which has an alkaline reaction and effervesces strongly with acids. With sodium cobaltic nitrite T.S. a saturated aqueous solution of the salt yields a yellow precipitate. Neutralize a saturated aqueous solution of the salt with potassium hydroxide T.S., add silver nitrate T.S., then just sufficient ammonia water to dissolve the white precipitate and boil the solution; silver is deposited on the sides of the test tube, forming a mirror. When 0.5 Gm. of the salt is dissolved in 3 mils of ammonia water, no insoluble residue remains (*starch, kaolin, calcium phosphate, or other insoluble matter*). Ten mils of an aqueous solution of the salt (1 in 50), made with the aid of just sufficient hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Ammonia is not evolved on heating the salt with a slight excess of potassium hydroxide T.S. Mix 1 Gm. of Potassium Bitartrate, in a platinum crucible, with 0.5 mil of sulphuric acid and 1 mil of nitric acid, and heat the mixture until fumes of sulphur trioxide begin to be liberated. Cool the resulting mass and treat it with 10 mils of distilled water and filter. The filtrate, upon being made slightly alkaline with potassium hydroxide T.S., does not yield a gelatinous precipitate soluble in excess of the reagent (alum). Heat 10 Gm. of Potassium Bitartrate with 15 mils of distilled water and add hydrochloric acid until the salt is dissolved, then add 2 mils of sulphurous acid and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 mil of sodium cyanide T.S., and follow this immediately with stronger ammonia water until the precipitate first formed is redissolved and the solution has a slight odor of ammonia. When it is cold, transfer the solution to a glass-stoppered cylinder graduated to 50 mils, dilute it with sufficient distilled water to measure 50 mils, and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not greater than the color of a control solution prepared as follows: Dissolve 2 Gm. of ammonium chloride (see Reagents, Part III) in 20 mils of distilled water, add 4 mils of a solution containing 0.08 Gm. of lead nitrate in 1000 mils of distilled water, and then 1 mil of diluted hydrochloric acid. Treat this solution with the same quantity of hydrochloric acid, sulphurous acid, sodium cyanide T.S., and stronger ammonia water, as used above, transfer it to another 50 mil glass-stoppered cylinder, and then dilute it with sufficient distilled water to make 50 mils and add 3 drops of sodium sulphide T.S. (before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia and the two cylinders used must be matched, be of practically colorless glass and have the same internal diameter) (*lead*).

"**Assay.**—Dissolve about 6 Gm. of Potassium Bitartrate, previously dried to constant weight at 100° C. (212° F.) and accurately weighed, in 100 mils of boiling distilled water, and titrate with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. It shows, in the dried salt, not less than 99.5 per cent. of $KHC_4H_4O_6$. Each mil of normal potassium hydroxide V.S. used corresponds to 0.18814 Gm. of $KHC_4H_4O_6$. Each gramme of Potassium Bitartrate, previously dried, corresponds to not less than 5.29 mils of normal potassium hydroxide V.S." *U. S.*

"A gritty white powder, or fragments of crystalline cakes. Taste acid. Soluble in 220 parts of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of tartrates. 1 gramme requires for neutralisation not less than 10.5 millilitres of *N/2 solution of sodium hydroxide.* Yields no characteristic *reactions* for copper, or iron, and not more than the slightest *reactions* for calcium, magnesium, sodium, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 2 parts per million." *Br.*

With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral potassium tartrate, and the tartrate of the base added. Several of these are important medicines. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boric acid. *Soluble Tartar* (*Tartarus boraxatus, Kali tartaricum boraxatum, Cremor tartari solubilis.*) Borax, 2 parts; distilled water, 20 parts. Dissolve, and add 5 parts purified cream of tartar. Agitate to dissolve, filter, evaporate to dryness, and powder.

The cream of tartar of commerce is now nearly pure potassium bitartrate. It has been, however, found purposely mixed with various substances, such as sand, clay, gypsum, flour, chalk, alum, and potassium sulphate. Sand, clay, and gypsum may be detected by their insolubility in a hot solution of potassium hydroxide; flour, by its striking a blue color with iodine; chalk, by its effervescing with dilute acids; alum (an unlikely sophistication), by its astringency, and any soluble sulphate, by its

causing a precipitate with barium chloride, not entirely soluble in nitric acid. The action of the last-mentioned test is explained by the fact that the barium tartrate is soluble and the sulphate insoluble in nitric acid. The best security against fraud is to purchase the crystals and have them powdered. Geo. F. Payne examined commercial cream of tartar; of ten samples obtained from grocery stores, five contained no cream of tartar whatever. Some of the spurious samples were mainly composed of a mixture of dried alum and acid calcium phosphate. (*Proc. A. Ph. A.*, 1897, 695.) These adulterations have for the most part long since disappeared from the market product. The U. S. Pharmacopœia admits a slight impurity. It should contain 99 per cent. of pure potassium bitartrate, and there is no difficulty in obtaining it in commerce of this quality. Coupland gives in *P. J.*, 1901, 282, the results of an examination of commercial cream of tartar as follows: While in 1884 the assays of cream of tartar revealed from 8 to 14 per cent. of calcium tartrate, the quality has continuously improved and it contained in 1901, 4.6 per cent. But cream of tartar of greater purity is by no means an exceptional article, potassium bitartrate of a quality of 98 and 99 per cent. being common, the latter coming from America. The competition among makers of "baking powders," into which it enters, explains in part the improvement in the quality of cream of tartar.

Composition.—Cream of tartar consists of one molecule of tartaric acid, $C_4H_4O_6.H_2$, in which one of the two hydrogen atoms has been replaced by an atom of potassium, forming the acid tartrate, $KHC_4H_4O_6$.

Uses.—Potassium bitartrate is a very mild saline cathartic, and an active diuretic. In small doses it acts as a cooling aperient and in large ones as a hydragogue cathartic, producing copious watery stools. It is much used in *dropsy*. It is frequently prescribed in combination with senna, sulphur, or jalap. (See *Confectio Sulphuris* and *Pulvis Jalapæ Compositus*.) Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some *febrile affections*, and frequently employed as a domestic remedy. The beverage called *imperial* (*potus imperialis*) is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar and half an ounce of fresh lemon peel. *Cream of tartar whey* is prepared by adding about two drachms of the bitartrate to a pint of milk. It may be given in dropsical diseases.

As a diuretic, cream of tartar may be administered in the dose of a drachm and a half or two drachms (5.8–7.7 Gm.) several times a day. It is believed to escape from the system unchanged, and hence is not available when an alkaline influence upon the blood or renal secretion is desired. In pharmacy, cream of tartar is employed to obtain the neutral potassium tartrate (soluble tartar), potassium and sodium tartrate (Rochelle salt), antimony and potassium tartrate (tartar emetic), and iron and potassium tartrate (tartarized iron). Deflagrated with potassium nitrate, or incinerated alone, it is converted into a pure form of potassium carbonate, called salt of tartar. In the laboratory it is used to procure potassium hydroxide in a pure state, and for making black and white flux. *Black flux* is prepared by deflagrating cream of tartar with half its weight of potassium nitrate, and *white flux*, by deflagrating it with twice its weight of the same salt.

Dose, aperient, one to two drachms (3.9–7.7 Gm.); cathartic, half an ounce to one ounce (15.5–31 Gm.).

POTASSII BROMIDUM. U. S., Br.

POTASSIUM BROMIDE Pot. Brom.

(pŏ-tăs'sĭ-ī brō'mĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 98.5 per cent. of KBr (119.02). Preserve it in well-closed containers." *U. S.* "Potassium Bromide may be obtained by the interaction of ferrous bromide with potassium carbonate. When dried at 100° it contains not less than 98 per cent. of pure potassium bromide, KBr." *Br.*

Bromide of Potassium; Bromuretum Potassicum, s. Kalicum; Bromure de Potassium, *Fr. Cod.;* Kalium bromatum, *P. G.;* Bromkalium, Kaliumbromid, *G.;* Bromuro di potassio, *It.;* Bromuro potasico, *Sp.*

No process is given in recent Pharmacopœias but in the 1870 U. S. P. a solution of ferrous bromide was formed, and this, by the addition of the solution of potassium carbonate, was decomposed so as to produce ferrous carbonate, which precipitated, while *potassium bromide* remained in solution. By straining, the precipitated carbonate was separated, and from the strained liquor potassium bromide was obtained by due evaporation. The reactions are as follows:

$$Fe + Br_2 = FeBr_2$$

$$FeBr_2 + K_2CO_3 = FeCO_3 + 2KBr$$

By boiling the mixture produced by the last reaction the bulky $FeCO_3$ is converted into the denser Fe_2O_3, and the separation of the potassium bromide solution is facilitated. In the Br. Pharm. 1885, by reaction between potassium hydroxide and bromine, the potassium bromide and bromate are produced in solution, and, having been obtained dry by evaporation, are exposed with the powder of charcoal to a red heat, whereby the potassium bromate is converted into potassium bromide by the separa-

tion of its oxygen. The remainder of the process consists in obtaining the bromide in crystals by solution in boiling water, which deposits it on cooling.

The reactions for this method are as follows:

$$6KOH + 6Br = 5KBr + KBrO_3 + 3H_2O$$

$$KBrO_3 + 3C = KBr + 3CO$$

Properties.—Potassium bromide is in "colorless, or white, cubical crystals, or as a granular powder; odorless, and having a strongly saline taste. It is permanent in the air. One Gm. of Potassium Bromide dissolves in 1.5 mils of water, about 250 mils of alcohol, and in 4.6 mils of glycerin at 25° C. (77° F.); also in 1 mil of boiling water and in about 21 mils of boiling alcohol. Its aqueous solution (1 in 20) is neutral or faintly alkaline to litmus. When the salt is heated upon platinum foil it decrepitates; upon further heating it fuses without decomposition and at a bright red heat volatilizes, communicating a violet color to a non-luminous flame. The addition of 5 mils of sodium bitartrate T.S. to 5 mils of an aqueous solution of the salt (1 in 5) produces a white, crystalline precipitate. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 10) produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. Dissolve 1 Gm. of Potassium Bromide in 10 mils of distilled water and add 0.1 mil of tenth-normal sulphuric acid V.S.; no color is produced by the subsequent addition of a drop of phenolphthalein T.S., even after heating (*alkali*). Add a few drops of ferric chloride T.S. to 10 mils of an aqueous solution of the salt (1 in 20), shake the mixture, and add 1 mil of chloroform; the latter does not acquire a violet tint (*iodide*). Drop 1 mil of diluted sulphuric acid upon about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Separate portions of 10 mils each of an aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, are not immediately rendered turbid by the addition of 1 mil of potassium sulphate T.S. (*barium*), nor by 1 mil of barium chloride T.S. (*sulphate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dry the salt to constant weight at 100° C. (212° F.) and proceed as directed under the Assay for bromides (see Part III, Test No. 5). It shows, in the dried salt, not less than 98.5 per cent. of KBr. Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.011902 Gm. of KBr. Each gramme of Potassium Bromide, previously dried, corresponds to not less than 82.8 mils nor more than 84.8 mils of tenth-normal silver nitrate V.S." *U. S.*

"Colorless, cubical crystals. No odor; taste pungent and saline. Soluble in 2 parts of *water*, and in 200 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of bromides. Loses not more than 1 per cent. of its weight when dried at 100° C. (212° F.); 0.5 gramme of this dried salt requires for complete precipitation not less than 41.2 or more than 42.5 millilitres of *N/10 solution of silver nitrate.* Yields no characteristic *reactions* for copper, iron, barium, calcium, magnesium, carbonates, bromates, or iodates, and not more than the slightest *reactions* for iodides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

According to Chas. D. Chase, the commercial salt often is decidedly alkaline, and will precipitate the alkaloids from the solution of their salts; a serious mishap from such cause is very conceivable.

Tests.—To determine the percentage of chloride in an impure bromide the process of Baudrimont, as improved by Falières, may be used. It is founded upon the fact that chlorides precipitate more silver than the bromides, because of the lower atomic weight of chlorine as compared with bromine; for an explanation see *P. J.*, 1872, p. 542. Prepare a titrated solution of 0.852 gramme of silver nitrate in 100 cubic centimeters of distilled water. It is necessary, by means of ferric chloride, salts of barium, and strong sulphuric acid in excess, to insure that there are present no other salts, such as potassium iodide, carbonate, or sulphate, or sodium nitrate, which would interfere with the results. Then dissolve one gramme of the bromide in thirty or forty grammes of water in a stoppered bottle, and add 1.427 grammes of silver nitrate in solution. When the precipitate has subsided, add, drop by drop, from a Gay-Lussac burette the titrated solution. If the bromide be pure, no precipitate forms; otherwise the number of cubic centimeters required to completely precipitate it equals the percentage of the chloride. An iodide of alkaline metal may be detected by adding to the solution of the bromide, palladium chloride, which will precipitate all the iodine in the form of palladium iodide, while the bromide of that metal will remain in solution. According to Bobieure and Herbelin, potassium bromide containing iodide may be purified by boiling with bromine water and evaporating, the liberated iodine and the excess of bromine being driven off during the evaporation. (*J. P. C.*, 4e sér., x, 166.)

Uses.—The effects of potassium bromide on the system are due chiefly to the bromine ion, although under certain conditions they may be more or less modified by the potassium. The bromides in sufficient concentration are depressants apparently to all forms of nervous tissue but show a marked selective action for certain centers. In the frog the most susceptible part is the sensory side of the spinal cord and it is possible in these animals to produce a condition of almost complete anesthesia and loss of reflex activity, with the voluntary motion well preserved. In man, however, the first effect seems to be upon the motor area of the brain and while these centers are not com-

pletely paralyzed there is a great reduction in the irritability of the psychomotor tract from doses insufficient to cause any marked diminution of the reflexes or distinct loss of sensation. With sufficient doses, however, both of these evidences of depression of the sensory cells of the cord may be apparent even in human beings. While after toxic quantities or in certain specially susceptible individuals there may be marked disturbances of intellection, this psychical depression is usually a late phenomenon. As far as the circulatory apparatus and other vital functions are concerned the bromides are practically inert. The old belief that the bromides were depressant to the heart was based upon experiments made with the potassium salt and it has been shown by Greene and Kruse (*J. A. M. A.*, 1913, lxi, p. 271), that the depressant action of this salt is due to its potassium rather than to its bromine. When used continuously over long periods of time the bromides exert a profound influence upon the nutritive processes which, however, is not clearly understood. Schultz (*Z. B.*, 1883, xix, p. 301), has found an increase in the quantity of nitrogen eliminated but a diminution in the output of phosphorus.

As the drug is eliminated very slowly, when used continuously it tends to accumulate in the system and in sufficient dose may give rise to the phenomena known as *bromism*. The symptoms are muscular weakness, general mental and bodily sluggishness, loss of memory, often marked sleepiness, depression of spirits deepening into complete apathy, lowering of temperature, and finally a universal depression of function, the patient lying in bed scarcely more than a feeble automaton. Fetor of breath is usually well marked, and an eruption of acne may be the first indication of the constitutional action of the drug. In some cases the effects of the drug upon the skin are most marked, and the pustules, under its continuous exhibition, become furuncular or go on to ulceration. A remarkable thing about bromism is the rapidity and completeness with which the symptoms clear up on ceasing the use of the drug even without any treatment. Despite the fact that it leaves the system through practically all the excretory organs, having been found in the sweat, saliva, urine, and intestinal mucus, it is eliminated very slowly and has been found in the urine as much as a month after the last dose.

The bromides are used in medicine to check *convulsions*, alleviate *pain*, to promote sleep, and to allay general nervous excitation. In *epilepsy* the bromides are the most potent remedial agents that we possess. Their influence, however, is that of a suppressant and rarely, if ever, do they produce a true cure; while under their use the patient may remain free from seizures for months and even years, their withdrawal is generally followed by a return of symptoms. In *tetanus* the fact that they can be given in almost unlimited quantity without serious depression of the circulation renders them of peculiar value for the control of the convulsions. In *strychnine poisoning*, although theoretically important, their action is generally too slow to be of much practical utility. As analgesics the bromides when given by themselves are of only secondary power, but they greatly enhance the anodyne effects of other drugs such as morphine or acetanilid. In *insomnia* they have been greatly abused. They differ sharply from the true somnifacients, such as chloral, in the fact that in ordinary quantity they have almost no depressant action upon the intellectual centers. Their value in promoting sleep is due rather to the obtunding of the general sensibilities so that those distractions, such as noise and bodily discomforts, which may act as contributing causes to the wakefulness, are less potent. They have been used very freely in all forms of functional disorders of the nervous system for some of which they are very useful, but for others entirely unsuited. In *hysteria* they are almost habitually prescribed, but it is extremely doubtful whether they have any effect which cannot be ascribed to the mere effect of taking medicine, at least as far as the immediate relief of symptoms. In *neurasthenia* their analgesic properties often make them useful and there is reason to believe that at times they may exercise a favorable influence upon the metabolism of the nerve centers. In *vomiting* of reflex origin, as that of pregnancy, at times they are of service. Among other conditions in which they are frequently employed may be mentioned *alcoholism, delirium tremens, various* forms of *sexual excitement*, as *nymphomania, urethral fever*, etc.

The dose of potassium bromide varies much according to the purpose for which it is administered and the length of time over which it is employed. In conditions like epilepsy in which the use of the drug is continued, once the system has come under its influence relatively small doses are required to maintain the beneficial impression. Thus, while in the beginning of the treatment 1 or 2 drachms (3.9–7.7 Gm.) a day may be required, after the action of the bromide has once been well established their influence may often be continued by 8 or 10 grains (0.5–0.65 Gm.) three times a day. In tetanus it is essential that large quantities be exhibited; as much as from one-half to one ounce (15.5–31 Gm.) should be administered in the twenty-four hours. When only one dose is given very large quantities may be safely administered, thus for the relief of pain a drachm is generally required and in severe strychnine poisoning one-half ounce (15.5 Gm.), properly diluted, may be exhibited at once.

Dose, ten to forty-five grains (0.65–3.0 Gm.).

POTASSII CARBONAS. U. S., Br.

POTASSIUM CARBONATE Pot. Carb. [Salt of Tartar]

(pŏ-tăs'sĭ-ī căr'bŏ-năs)

"It contains, when dried to constant weight at 180° C. (356° F.), not less than 99 per cent. of K_2CO_3 (138.20). It contains not more than 15 per cent. of moisture. Preserve it in air-tight containers." *U. S.* "Potassium Carbonate may be obtained by the interaction of potassium sulphate and calcium carbonate. It contains not less than 81.5 per cent. of pure potassium carbonate, K_2CO_3." *Br.*

Carbonate of Potassa from Pearlash; Potassii Carbonas Purus, Sal Tartari; Kali Carbonicum, Carbonas Potassicus, s. Kalicus; Carbonate de Potasse pur, Sel de Tartre, *Fr. Cod.*; Kalium Carbonicum, *P. G.*; Kohlensaures kali, Kaliumcarbonat, *G.*; Carbonato di potassio, *It.*; Carbonato potasico, *Sp.*

The present U. S. Pharmacopœia does not give a process for this salt.

The object of the process (formerly official) is to purify the impure *potassium carbonate*, or pearlash. This generally contains certain insoluble impurities, as well as small portions of potassium sulphate, silicate, and chloride, as explained under another head. (See *Potassii Carbonas Impura.*) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are disposed of, as well as the greater part of the foreign salts, which, being much less soluble than the potassium carbonate, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of *cold water*, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor obtained by decantation or filtration is then evaporated to dryness. The former official process was conducted very much in this way, cold water being employed, and about equal weights of alkali and water being used. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, formerly ordered by the Dublin College, were useful directions. In no case should the undissolved residue be washed with a fresh portion of water, as by such a proceeding the foreign salts, which it is the object of the process to separate, would be dissolved. Iron vessels are directed, because this metal is not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better, when the solution is brought nearly to dryness, to keep it on the fire at a reduced heat until the process is finished, than to remove it the moment it thickens. According to Berzelius, a more productive process for purifying pearlash, though the resulting salt is not so pure as when obtained in the way just described, is to dissolve the pearlash in more than its weight of water, to evaporate the solution until it has the sp. gr. 1.52, and then to put it in a cool place, that the foreign salts, principally potassium sulphate and chloride, may crystallize. The solution is then decanted, and evaporated to dryness. To get rid of the silica, Rieckher proposes to evaporate the solution, exempt from sulphate, to dryness, to moisten the residue with solution of ammonium carbonate, and again evaporate. The silica separates, and passes into the insoluble state at the temperature necessary for evaporation. By again dissolving and evaporating, the carbonate is obtained free from this impurity. (*Chem. Cb.*, 1863, p. 158.)

"Take of Impure Carbonate of Potassium [pearlash] *thirty-six troyounces;* Water *two pints and a half.* Dissolve the Impure Carbonate in the Water, and filter the solution; then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula so as to form a granular salt." *U. S.* 1870.

Impure Potassium Carbonate was official in 1870. It is commonly known as *Pearlash, Pearlashes, Impure Potassa; Potasse du Commerce,* Fr.; *Rohe Pottasche,* G. The alkali called potassa is the hydroxide of the metal potassium. (See *Potassium.*) It exists in various states of purity admixed with carbonate. In its most impure state, it is the common potash or *potashes* of commerce. This, subjected to calcination, is rendered purer, and is then called *pearlash,* the form of the alkali which was formerly recognized as *Potassii Carbonas Impura.*

Natural State and Preparation.—Potash and pearlash of commerce were formerly procured largely from the ashes of wood by lixiviation, and the subsequent evaporation of the solution obtained. The alkali exists in the wood in combination with various organic acids, and is left behind after the incineration, principally in the form of carbonate according to the following reaction, taking the acetate as an example:

$$2KC_2H_3O_2 + O_4 = K_2CO_3 + CO_2 + 3H_2O$$

The wood is burned on the ground, in a place sheltered from the wind. The ashes consist of a soluble and an insoluble portion. The soluble part is made up of potassium carbonate, together with potassium sulphate, phosphate, and silicate, and potassium and sodium chlorides; the insoluble portion, of calcium, and aluminum salts, oxidized iron and manganese carbonate and phosphate, and a little carbonaceous matter that has escaped combustion. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in large iron kettles, which for several days are kept constantly full. The evaporation is continued until the mass has become of a black color and of the consistence of brown sugar. It is now subjected to as powerful a heat as can be produced by the best wood fire for a number of hours, by which it is fused. During the fusion the combustible impurities are for the most part burnt out, and a gaseous matter is emitted, which agitates the more fluid part. When the fusion is complete, the liquid becomes quiescent, and looks like

melted iron. It is now transferred, by means of large iron ladles, to iron pots, where it congeals in cakes. These are broken up and packed in tight barrels, and constitute the *potash* of commerce. If it is intended to make *pearlash*, the process is varied. In this case the black matter of the consistence of brown sugar, called *black salts* by our manufacturers, instead of being fused, is transferred from the kettles to a large oven-shaped furnace so constructed that the flame may play over the alkaline mass, which in the meantime is stirred by means of an iron rod. The ignition is in this way continued until the combustible impurities are burnt out, and the mass, from being black, becomes of a bluish-white color. The extraction from wood ashes is no longer practised in the United States, but is still carried out, to some extent in Canada and the northern countries of Europe, especially Russia.

Within recent years the residues of beet root molasses, after fermentation of the sugar and distillation of the spirit, have served as a source of potash. The molasses contains 40 to 50 per cent. of sugar and 3 to 4 per cent. of potassium salts. The *suint* of sheep's wool constitutes another source of potashes. The potassium in this case being combined with fatty substances. Potassium sulphate, either the crude salt from Stassfurt deposits or that obtained from the crude potassiuum chloride of the same locality, is also converted into carbonate by a process analogous to Leblanc's soda process. The principle of the ammonia soda process can also be applied to the crude potassium chloride of Stassfurt, with this difference in the practical operation, that, because of the ready solubility of the acid potassium carbonate, trimethylamine is used instead of ammonia, as the chloride of this base is much more soluble than is ammonium chloride.

A review of the recent effort to develop a potash industry in the United States will be found in the article by F. M. de Beers in *Metallurgical and Chem. Engineering*, November 1, 1916. (See also under *Potassii Nitras*, p. 906.)

Crude potash is now prepared in large amount from the "abraum" salts of the German rock salt deposits, in a manner analogous to the preparation of sodium carbonate from sodium chloride. The mixture of magnesium and potassium chlorides found so abundantly in these deposits may also be saturated with carbon dioxide, when an insoluble double salt separates out.

$$3MgCO_3 + 2KCl + CO_2 + 9H_2O = 2(MgCO_3.KHCO_3.4H_2O) + MgCl_2$$

By heating this with water under pressure it decomposes into insoluble magnesium carbonate and soluble potassium carbonate, which remains in solution and is obtained therefrom by evaporation.

$$2MgCO_3.KHCO_3.4H_2O = K_2CO_3 + 2MgCO_3 + 5H_2O + CO_2$$

Other minerals have also become the source of potassium salts, especially a deposit of mixed potassium and magnesium chlorides, overlying a bed of common salt, at Stassfurt, near Madgeburg, in Prussia.

Potassium carbonate may be produced from crude potassium sulphate by the following reaction:

$$K_2SO_4 + CaCO_3 + K_2CO_3 + CaSO_4$$

Feldspar, marl and other minerals, rich in potassium compounds, are now being utilized for the production of potassium carbonate and other salts of the element.

In round figures the importations into the United States of Stassfurt minerals in recent years are: potassium chloride (80 per cent.), 250,000 tons; potassium sulphate (90 per cent.), 50,000 tons; manure salts (20–38 per cent.), 200,000 tons; kainite (12–15 per cent.), 500,000 tons.

Properties.—Potash is in the form of fused masses, of a stony appearance and hardness, and a caustic burning taste. Its color is variegated, but reddish and dark brown are the predominant hues. When exposed to the air, it absorbs moisture and deliquesces, and, if sufficiently long exposed, finally becomes liquid. Pearlash is of a white color, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire, hard, concrete mass. In commerce it is found in coarse powder, intermingled with lumps as dug out of the casks, presenting an opaque granular appearance, like table salt or common sugar. It is deliquescent, and has a burning alkaline taste. It is soluble in water, with the exception of impurities. It differs from potash principally in containing fewer combustible impurities and in being less caustic and deliquescent. The coloring matter of both these forms of alkali is derived from carbonaceous impurities and small portions of iron and manganese.

Composition.—The basis of both potash and pearlash is potassium carbonate, but this is associated with certain salts and with insoluble impurities. Several varieties of potash found in commerce were analyzed by Vauquelin, whose principal results are contained in the table below. The quantity examined of each kind was 1152 parts.

These results, calculated for 100 parts, show that the American potash contains 74 per cent. of pure alkali hydroxide and the Russian 67 per cent. Pearlash, it is seen, is more rich in carbonic acid than potash, and this result of analysis corresponds with the qualities of the two substances as prepared in the United States—potash being known to be far more caustic than pearlash. Besides the impurities shown by the table, potassium phosphate and silicate and sodium chloride are present. J. U. Lloyd, in the *Proc. A. Ph. A.*, 1892, p. 190, gives the results of an examination of American commercial potashes; he found that what was sold

in the market as "first sorts" was largely adulterated with common salt, this addition made to the melted potash in the kettle tending to whiten the crude potash and give it increased value in the eyes of those consumers who judge merely by appearance and do not take the trouble to assay it. According to Stevenson Macadam, the potashes of commerce contain iodine and a trace of bromine, which shows that the forest trees from which the alkali is obtained must contain a very minute proportion of these non-metallic elements.

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it is important to possess an easy method of ascertaining its quality in that respect. (See *Potassii Hydroxidum.*)

Pearlash, from its impurity, is never used as a medicine. Purified to a certain extent, it takes the name of potassium carbonate.

Inasmuch as potassium carbonate is now largely made electrolytically from the chloride, the presence of potassium chlorate as an impurity has been reported in the commercial carbonate.

Properties.—It is officially described as "a white, granular powder; odorless, and having a strongly alkaline taste; very deliquescent. One Gm. of Potassium Carbonate dissolves in 0.9 mil of water at 25° C. (77° F.); also in 0.7 mil of boiling water; insoluble in alcohol. An aqueous solution of Potassium Carbonate (1 in 20) is strongly alkaline to litmus and phenolphthalein T.S., and effervesces with acids. When heated to 180° C. (356° F.), the salt loses all the water which it may have retained or absorbed; at a bright red heat it melts, and at a white heat it volatilizes, communicating to a non-luminous flame a violet color with not more than a transient yellow tinge. An aqueous solution of the salt (1 in 10) yields with an excess of tartaric acid T.S. a white crystalline precipitate of potassium bitartrate. No residue is left on dissolving 1 Gm. of the salt in 20 mils of distilled water (*earthy impurities*). An aqueous solution of Potassium Carbonate (1 in 50), mixed with a slight excess of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Take about 3 Gm. of Potassium Carbonate, weigh accurately, and dry to constant weight in an air bath at 180° C. (356° F.); it loses not more than 15 per cent. in weight.

"Assay.—Dissolve about 3 Gm. of Potassium Carbonate, previously dried to constant weight at 180° C. (356° F.), and accurately weighed in a stoppered weighing-bottle, in 25 mils of distilled water and titrate with normal sulphuric acid V.S., methyl orange T.S. being used as indicator. It shows, in the dried salt, not less than 99 per cent. of K_2CO_3. Each mil of normal sulphuric acid V.S. used corresponds to 0.06910 Gm. of K_2CO_3. Each gramme of Potassium Carbonate, previously dried, corresponds to not less than 14.33 mils of normal sulphuric acid V.S." *U. S.*

"A white crystalline powder, very deliquescent. Taste alkaline and caustic. Soluble in 1 part of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of carbonates. 1 gramme requires for neutralisation not less than 11.8 millilitres of *H/1 solution of sulphuric acid.* Loses not more than 18.5 per cent. of its weight when exposed to a red heat. Yields no characteristic *reactions* for copper, aluminum, calcium, magnesium, sodium, cyanides, nitrates, sulphates, sulphides, or thiosulphates, not more than the slightest *reactions* for iron, and no strongly marked *reactions* for chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million." *Br.*

The official test permits the presence of 1 per cent. of impurities. It is incompatible with acids and acidulous salts, ammonium chloride and acetate, lime water, calcium chloride, magnesium sulphate, alum, tartar emetic, silver nitrate, ammoniated copper and ammoniated iron, ferrous sulphate, tincture of ferric chloride, calomel and corrosive sublimate, lead acetate and subacetate, and zinc sulphate. It is not decomposed by iron and potassium tartrate.

A solution of the salt, on exposure to the air, or on addition of an acid, deposits flocculi consisting of hydrated silica, resulting from the decomposition of potassium silicate, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbon dioxide.

Composition.—Potassium carbonate, after exposure to a red heat, is anhydrous. Obtained by the usual processes, it contains two molecules of potassium carbonate and three of water. When exposed to the air, potassium carbonate absorbs sufficient water, before losing its solid form, to give it three molecules; with more it begins to deliquesce. *Potassium percarbonate,* $K_2C_2O_6$, was made by Constans and von Hansen by electrolyzing a saturated solution of potassium carbonate, and gradually lowering the temperature. It is a bluish amorphous powder, hygroscopic and decomposing water at ordinary temperatures, bicarbonate being formed. (*Chem. News,* 1897, 170; 1898, 65.)

Uses.—Potassium carbonate is occasionally used as an antacid in *dyspepsia,* a diuretic in *dropsy,* and an antilithic in *uric acid gravel,* but the purpose to which it was most commonly applied in former years was the formation of the *neutral mixture* and the *effervescing draught.* It should always be administered in dilute solution. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours; three ounces in very concentrated solution have been recovered from by an adult female. (Espagne, *A. G. M.,* Fèv. 1867.) The antidotes are the fixed oils and the vegetable acids. As a local remedy in *cutaneous affections,* potassium carbonate is used in the form of bath, lotion, and ointment. From eight to sixteen ounces may be used for a single bath, the quantity being gradually in-

creased. Lotions may be made by dissolving two or three drachms in a pint of water; and ointments, by rubbing from ten grains to a drachm with an ounce of lard.

Dose, five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Mistura Carminativa, *N. F.;* Unguentum Sulphuris Alkalinum, *N. F.*

POTASSII CHLORAS. U. S., Br.

POTASSIUM CHLORATE Pot. Chloras

(pŏ-tăs'sĭ-ī ĉhlō'răs)

"It contains not less than 99 per cent. of $KClO_3$ (122.56). Preserve it in well-closed containers. *Great caution should be observed in handling* it, as dangerous explosions are liable to occur when it is heated or subjected to concussion or trituration with organic substances (cork, tannic acid, dust, sugar, etc.), or with sulphur, sulphides, hypophosphites, or other easily oxidizable substances." *U. S.* "Potassium Chlorate, $KClO_3$, may be obtained by passing chlorine into water holding lime or magnesia in suspension, treating the clarified liquid with potassium chloride, and subsequently crystallising out the potassium chlorate." *Br.*

Chlorate of Potash; Kali Oxymuriaticum, Kali Muriaticum Oxygenatum, Chloras Potassicus, s. Kalicus; Hyperoxymuriate of Potassa; Chlorate de Potasse, *Fr. Cod.;* Kalium Chloricum, *P. G.;* Kaliumchlorat, Chlorsaures Kali, *G.;* Clorato di potassio, *It.*

In the U. S. and Br. Pharmacopœias no processes are given for potassium chlorate.

Preparation.—The salt may be obtained by the process of Graham, which consists in mixing potassium carbonate with an equivalent quantity of calcium hydroxide before submitting it to the action of chlorine. The gas is absorbed with avidity, and the mass becomes hot, while water is given off. The lime converts the carbonate into potassium hydroxide, and the reaction then takes place between six molecules of potassium hydroxide and six atoms of chlorine, with the result of forming five molecules of potassium chloride and one of potassium chlorate, while three molecules of water are eliminated, the reaction being analogous to the first one given under the milk of lime method (see below).

The products are, therefore, calcium carbonate, potassium chloride, and potassium chlorate. The chloride and chlorate are separated from the carbonate by solution in hot water, and the chlorate from the chloride by priority of crystallization; a large proportion of the potassium hydroxide is lost by being converted into potassium chloride. In the process which has been generally employed for the commercial manufacture of potassium chlorate this is obviated, as follows. Chlorine is passed into a solution of milk of lime having a specific gravity of 1.04 until the liquid is nearly saturated. The clear solution is evaporated until it has a specific gravity of 1.18, and then potassium chloride added, and the mixture boiled down until a specific gravity of 1.28 is attained. On cooling, crystals of potassium chlorate separate out. The reactions here are

$$6Ca(OH)_2 + 6Cl_2 = 5CaCl_2 + Ca(ClO_3)_2 + 6H_2O$$
$$Ca(ClO_3)_2 + 2KCl = CaCl_2 + 2KClO_3$$

Pechiney's improvement on this process is to separate the greater part of the calcium *chloride* from the calcium *chlorate* before adding the potassium chloride. For details, see *N. R.,* Feb., 1882.

The potassium chlorate of commerce is also prepared by the reaction of solutions of potassium chloride and calcium hypochlorite, with the assistance of heat. The potassium chlorate crystallizes during the refrigeration of the liquor, and calcium chloride remains in solution:

$$2KCl + 3Ca(OCl)_2.CaCl_2 = 2KClO_2 + 6CaCl_2$$

This process has been further improved in Muspratt and Eschellmann's English patents (*J. Soc. Chem. Ind.,* iii, pp. 349 and 445) by substituting magnesia for lime, as potassium chlorate is much less soluble in magnesium chloride solutions than in those of calcium chloride, and consequently much less chlorate is left in solution. The process is said to increase the production of chlorate by from 15 to 20 per cent. It may also be produced by the simple heating of solution of potassium hypochlorite:

$$3KClO = KClO_3 + 2KCl$$

Potassium chlorate is now made commercially, in increasing amounts by the electrolysis of potassium chloride solution at Niagara Falls, and elsewhere, in this country and in various places in Europe. The potassium chloride, on electrolysis in a cell without diaphragm, yields first potassium hypochlorite, but as the temperature of the bath is kept above 50° C. (122° F.), it is changed to a mixture of chlorate and chloride, from which, on cooling, the former crystallizes out.

Properties.—Potassium chlorate is in "colorless, lustrous, monoclinic prisms or plates, or as a white granular powder; odorless, and having a saline taste. It is permanent in the air. One Gm. of Potassium Chlorate dissolves in 11.5 mils of water at 25° C. (77° F.); also in 1.8 mils of boiling water; almost insoluble in alcohol; soluble in glycerin. An aqueous solution of the salt (1 in 20) is neutral to litmus. When heated the salt melts, gives off oxygen, and finally leaves a residue of potassium chloride, readily soluble in water and yielding with silver nitrate T.S. a white precipitate, insoluble in nitric acid, but readily soluble in ammonia water. To a non-luminous flame it imparts a violet color. With an excess of tartaric acid T.S. a solution of the salt (1 in 20) slowly yields a scant, white, crystalline precipitate; with platinic chloride T.S., a similar solution yields a yellow

crystalline precipitate. Add about 0.2 Gm. of the salt to 1 mil of hydrochloric acid; the liquid assumes a deep greenish-yellow color, and chlorine and oxides of chlorine are evolved. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3)." *U. S.*

"Colorless monoclinic crystals. Taste cool, saline. Soluble in 16 parts of *water.* Moistened with *hydrochloric acid* it evolves a yellow gas with an odor of chlorine. Yields no characteristic *reactions* for iron, calcium, magnesium, sodium, ammonium, or nitrates, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Assay.—"Transfer to a 250 mil flask about 0.1 Gm. of Potassium Chlorate, accurately weighed, and dissolve it in 10 mils of distilled water, then add 25 mils of acidulated ferrous sulphate T.S. to the solution. Prepare a valve stopper by taking a piece of rubber tubing of convenient diameter and about 5 cm. in length, placing a piece of glass rod in one end and slipping the other end over a glass tube which passes through a perforated stopper of a size convenient to fit the flask used. Cut a longitudinal slit about 15 mm. long in one side of the rubber tube about half way up. Insert this stopper in the flask and boil the mixture for ten minutes. Now cool the mixture, add 10 mils of manganous sulphate T.S. and titrate the excess of ferrous sulphate with tenth-normal potassium permanganate V.S. At the same time conduct a parallel experiment with another portion of 25 mils of acidulated ferrous sulphate T.S. and subtract the result of the former titration from that of the latter. It shows not less than 99 per cent. of $KClO_3$. Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.0020427 Gm. of $KClO_3$. Each gramme of Potassium Chlorate corresponds to not less than 484.7 mils of tenth-normal potassium permanganate V.S." *U. S.*

Frank X. Moerk (*J. A. P. A.*, 1913, p. 155), reviews various methods for the determination of chlorates and recommends the following: Place 0.1 Gm. of the salt in a glass-stoppered bottle and add 10 mils of distilled water and 15 mils 10 per cent. potassium bromide solution, and 20 mils HCl (sp. gr. 1.20) and allow to stand 40 minutes tightly stoppered. Cool by immersing in water, add 20 mils potassium iodide solution (10 per cent.), carefully rinsing the stopper and neck of the bottle, and titrate with tenth-normal sodium thiosulphate V.S. A blank test should be made with the reagents to prove that no iodine is liberated by them alone.

Potassium chlorate is characterized also by becoming first yellow and then red by admixture with a little sulphuric acid, and by the action of that acid evolving chlorine tetroxide (Cl_2O_4), known by its yellow color, and its explosive property when heated; by its bleaching power when mixed with hydrochloric acid and then with water, and by its property of exploding violently when triturated with a small portion of sulphur or phosphorus or kermes mineral. Potassium chlorate consists of one atom of potassium in combination with the chloric acid group. This salt is an excellent test of manganese existing in organic matter. If a small portion of such matter, containing even a trace of manganese, be thrown on the surface of the *pure* melted salt in a test-glass, after the combustion has ceased the cooled saline mass will be found to have a rose or pinkish tint, caused by the formation of potassium permanganate. (*Neues Repert.*, vi, 247.) A similar discoloration of the salt, produced by the use of pure charcoal in the same manner, will evince the presence of manganese in the chlorate as an impurity.

Uses.—In the belief that potassium chlorate yielded oxygen in the system, it was formerly used in the treatment of various infectious diseases as well as a local disinfectant, but as decomposition of the salt takes place only in highly acid media this liberation in the body cannot occur. As a local antiseptic it is extremely feeble. According to the experiments of Sternberg a 4 per cent. solution—which is almost saturation at ordinary temperatures—is without germicidal power. It is used at present solely as a local remedy in *stomatitis, pharyngitis, vaginitis,* and other forms of *catarrh* as well as in *hemorrhoids* and *indolent ulcers.* Its beneficial influence in these conditions is due to its stimulant saline properties combined with a mild astringent effect. On the theory that it would be eliminated through the salivary glands and keep the mouth constantly bathed with a solution, it has been recommended to administer the drug internally in mercurial *ptyalism* and other inflammatory conditions of the buccal cavity, but as the larger portion of the drug is excreted through the kidneys this use does not commend itself to the thinking physician.

In overdose potassium chlorate is an active poison, four drachms of it having caused death in the adult. The symptoms produced are violent vomiting, profuse diarrhea, excessive dyspnea, great failure of the heart's action, and marked cyanosis. The urine is lessened in quantity, albuminous, often of a dark reddish-brown or blackish color, and containing tube casts and the débris of blood corpuscles. In some cases there have been marked nervous symptoms, such as cramps, delirium, coma, etc. The lesions found after death are those of gastro-enteritis and acute nephritis, with alteration in the character of the blood due to the development in it of methæmoglobin. On account of their irritant action on the kidneys, large doses are especially dangerous in *diphtheria.*

Dose, from five to fifteen grains (0.32–1.0 Gm.).

POTASSII CITRAS. U. S., Br.

POTASSIUM CITRATE Pot. Cit.

(pŏ-tăs'sĭ-ī cī'trăs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of $K_3C_6H_5O_7 + H_2O$ (324.36). Preserve it in well-closed containers." *U. S.*
"Potassium Citrate may be obtained by the interaction of citric acid and potassium carbonate. It contains not less than 99 per cent. of pure potassium citrate, $K_3C_6H_5O_7,H_2O$." *Br.*

Kalium Citricum, Citras Potassicus, s. Kalicus; Citrate of Potash; Citrate de Potasse, *Fr.*; Kaliumcitrat, Citronsaures Kali, *G.*

Potassium citrate was known formerly by the name of *salt of Riverius.* In the U. S. formula of 1870, mutually saturating proportions of the acid and bicarbonate were intended to be employed, the latter ingredient being preferred to the carbonate on account of its greater purity. The potassium of the bicarbonate unites with the citric acid to form the potassium citrate, and the carbon dioxide escapes, producing effervescence.

$$3KHCO_3 + H_3C_6H_5O_7 = K_3C_6H_5O_7 + 3CO_2 + 3H_2O$$

The resulting solution is directed to be evaporated to dryness, as affording the most convenient form for use. The granulation ordered has a tendency to retard the deliquescence of the citrate. The British 1885 process differed only in the use of the carbonate instead of the bicarbonate, and in providing more carefully for an exact neutralization.

Properties.—Potassium citrate is crystallizable, but, as usually seen, is in the form of a granular powder. The U. S. P. recognizes both forms, and describes it "as transparent, prismatic crystals, or as a white, granular powder; odorless, and having a cooling, saline taste. It is deliquescent when exposed to moist air. One Gm. of Potassium Citrate dissolves in 0.6 mil of water at 25° C. (77° F.); almost insoluble in alcohol; freely soluble in glycerin. An aqueous solution of the salt (1 in 20) is alkaline to litmus but is not reddened by one drop of phenolphthalein T.S. When heated above 100° C. (212° F.), the salt begins to lose water and at about 200° C. (392° F.) the water of crystallization is completely lost. At a higher temperature the salt begins to decompose, turns brown, and upon further heating carbonizes and emits inflammable gases which have a very pungent, acrid odor. At a red heat a residue remains, which has an alkaline reaction and strongly effervesces with acids. An aqueous solution of Potassium Citrate (1 in 10) yields a white, crystalline precipitate with sodium bitartrate T.S. Mix 10 mils of an aqueous solution of the salt (1 in 20) with 10 mils of calcium chloride T.S.; the liquid remains clear until it is boiled, when a white, granular precipitate is produced. A solution of 1 Gm. of Potassium Citrate in 1 mil of distilled water does not deposit any precipitate on the addition of 1 mil of acetic acid (*tartrate*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of the salt meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Dry the salt to constant weight in a desiccator over sulphuric acid, and proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows, in the dried salt, not less than 99 per cent. of $K_3C_6H_5O_7 + H_2O$. Each mil of half-normal sulphuric acid V.S. used corresponds to 0.05406 Gm. of $K_3C_6H_5O_7 + H_2O$. Each gramme of Potassium Citrate, previously dried, corresponds to 18.3 mils of half-normal sulphuric acid V.S." *U. S.*

The British Pharmacopœia gives the following tests of its character:

"A white, granular, or crystalline powder. Taste saline, feebly acid. Soluble in 1 part of *water.* Yields the *reactions* characteristic of potassium and of citrates. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 13.3 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for iron, calcium, magnesium, sodium, carbonates, or tartrates, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million." *Br.*

As citric acid is tribasic, this salt consists of three atoms of potassium combined with the citric acid radical $C_6H_5O_7$, and with this one molecule of water, its formula being $K_3C_6H_5O_7 + H_2O$.

Uses.—Potassium citrate is a type of those drugs which increase various secretions by what is known as their salt action. This group of drugs, which includes most of the non-toxic crystalloids, act by increasing the saline concentration of the blood, disturbing the osmotic balance between this fluid and the surrounding tissues thereby attracting water into the vessels and tending towards the production of a hydremic state. This tendency towards an increase in the volume of the blood is counteracted by greater activity on the part of the glandular structures. Not only is the secretion of urine greater, but there is also an increase in the bronchial, sweat, and other glands. The therapeutic uses of potassium citrate, however, are not due alone to this action. The citrates being oxidized in the body into carbonates, the salt tends to correct any systemic hyperacidity; and the potassium apparently increases the completeness of bodily combustion. This combination of actions makes the drug of peculiar value in those forms of metabolic disturbances accompanied with the over-production of uric acid, such as *acute* or *chronic rheumatism* and *gout.* It is, however, a valuable drug in a large variety of other condi-

tions, thus in certain types of *nephritis*, especially when there is diminution in the elimination of solid matters, it is of much service as a diuretic; it is valuable in cases of *cystitis* with hyperacidity of the urine. In *fevers* it is often useful, either for its diuretic or diaphoretic effect, and is especially grateful in forms of the *neutral mixture* or *effervescing draught*. In the early stages of *acute bronchitis* or *tracheitis* by increasing the secretion of the mucous glands it indirectly exercises a sedative action on the inflammatory mucous membrane. It may be most pleasantly exhibited in conjunction with lemon juice which in no way lessens the alkalizing effect.

Dose, of the citrate, from twenty to forty grains (1.3–2.6 Gm.). When a decided effect upon the system is desired, as much as an ounce (31 Gm.) of it may be given in twenty-four hours.

Off. Prep.—Potassii Citras Effervescens, *U. S.*

POTASSII CITRAS EFFERVESCENS. U. S.

EFFERVESCENT POTASSIUM CITRATE Pot. Cit. Eff.

(pŏ-tăs'sĭ-ī cī'trăs ĕf-fẹr-vĕs'cĕnṣ)

"Potassium Citrate, *two hundred grammes* [or 7 ounces av., 24 grains]; Sodium Bicarbonate, dried and powdered, *four hundred and seventy-seven grammes* [or 16 ounces av., 361 grains]; Tartaric Acid, dried and powdered, *two hundred and fifty-two grammes* [or 8 ounces av., 389 grains]; Citric Acid, unefflorescd crystals, *one hundred and sixty-two grammes* [or 5 ounces av., 313 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Dry the potassium citrate on a water bath until it ceases to lose weight; after powdering the dried salt, mix it intimately with the powdered citric acid and tartaric acid, then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.). Manipulate the mixture carefully with a wooden spatula, and, when it has become moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Immediately transfer the salt to suitable containers and seal them tightly. Care must be taken to prevent the salt from coming in contact with air containing moisture." *U. S.*

The process of the U. S. P. IX is identical with that of the U. S. P. VIII, but differs from that formerly official, mainly in the absence of sugar which has a tendency to discolor and the use of potassium citrate instead of potassium bicarbonate and citric acid.

This official effervescent salt affords an agreeable mode of administering potassium citrate. It is more prone to exert a laxative effect because of the sodium tartrate formed.

Dose, from one to two drachms (3.9–7.7 Gm.).

POTASSII ET SODII TARTRAS. U. S. (Br.)

POTASSIUM AND SODIUM TARTRATE Pot. et Sod. Tart. [Rochelle Salt]

(pọ-tăs'sĭ-ī ĕt sō'dĭ-ī tär'trăs)

"It contains not less than 73.72 per cent. nor more than 77.39 per cent. of anhydrous potassium and sodium tartrate, corresponding to not less than 99 per cent. of the crystallized salt [$KNaC_4H_4O_6 + 4H_2O = 282.20$]. Preserve it in well-closed containers." *U. S.* "Sodium Potassium Tartrate may be obtained by neutralising Acid Potassium Tartrate with Sodium Carbonate. It contains not less than 98 per cent. of pure sodium potassium tartrate, $NaKC_4H_4O_6,4H_2O$." *Br.*

Sodii et Potassii Tartras, *Br.;* Sodium Potassium Tartrate; Tartrate of Potassium and Sodium; Soda Tartarata; Sodæ et Potassæ Tartras, *Br.* 1864, *U. S.* 1850; Sodæ Potassiotartras, Natro-kali Tartaricum; Tartarated Soda; Sal Polychrestum Seignetti, Tartras Potassico sodicus; Tartrate de Potasse et de Soude, *Fr. Cod.;* Sel de Seignette, Soude Tartarisée, *Fr.;* Tartarus Natronatus, *P. G.;* Seignettesalz, Kaliumnatriumtartrat, *G.;* Tartrate sodico-potassico, *It.;* Tartrato sodico-potasico, *Sp.*

This salt cannot be made profitably on the small scale (for U. S. process, 1870, see the *U. S. Dispensatory*, 19th edition, page 1000); it is a double salt, consisting of a molecule of tartaric acid, $C_4H_4O_6.H_2$, in which one of the basic hydrogen atoms is replaced by potassium and the other by sodium. The theory of its formation is very simple, being merely the replacement of the hydrogen in the potassium bitartrate by the sodium of the sodium carbonate, the carbon dioxide of which escapes with effervescence. The quantities of the materials for mutual saturation are 1224.02 parts of monohydrated carbonate and 376.28 of bitartrate, or one molecule of monohydrated sodium carbonate to two molecules of the acid tartrate.

$$2KHC_4H_4O_6 + Na_2CO_3H_2O = 2KNaC_4H_4O_6 + CO_2 + 2H_2O$$

Properties.—Potassium and sodium tartrate is in the form of "colorless, transparent, rhombic prisms, or as a white powder; odorless, and having a cooling, saline taste. The crystals slightly effloresce in dry air. One Gm. of Potassium and Sodium Tartrate dissolves in 0.9 ml of water at 25° C. (77° F.); almost insoluble in alcohol. An aqueous solution of the salt (1 in 20) is alkaline to litmus, but is not reddened by a drop of phenolphthalein T.S. When heated to about 74° C. (165.2° F.), the salt fuses to a colorless liquid, which at a higher temperature froths, becomes brown, and gradually carbonizes, while inflammable vapors are emitted, having the odor of burning sugar. Finally, a black residue is left, consisting of potassium and sodium carbonates with carbon. To a non-luminous flame this residue imparts an intensely yellow color. An aqueous solution of the salt (1 in 10) yields a white, crystalline precipitate with an equal volume of acetic acid. An aqueous solution of the salt (1 in 10) yields with silver nitrate T.S. a white precipitate which

becomes black on boiling. An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3). Five mils of an aqueous solution of the salt (1 in 10), when heated with potassium hydroxide T.S., does not evolve *ammonia*. Dissolve 10 Gm. of Potassium and Sodium Tartrate in 20 mils of distilled water, add 2 mils of sulphurous acid and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 mil of sodium cyanide T.S. and follow this immediately with stronger ammonia water until the precipitate formed is redissolved and the solution has a slight odor of ammonia. When cold, transfer the solution to a glass-stoppered cylinder, graduated to 50 mils, dilute it with sufficient distilled water to measure 50 mils and add 3 drops of sodium sulphide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface, is not greater than the color of a control solution prepared as follows: Dissolve 2 Gm. of ammonium chloride (see Reagents, Part III) in 20 mils of distilled water, add 4 mils of a solution containing 0.08 Gm. of lead nitrate in 1000 mils of distilled water, and then 1 mil of diluted hydrochloric acid. Treat this solution with the same quantity of hydrochloric acid, sulphurous acid, sodium cyanide T.S. and stronger ammonia water, as used above, transfer it to another 50 mil glass-stoppered cylinder, and then dilute it with sufficient distilled water to make 50 mils and add 3 drops of sodium sulphide T.S. (before adding the sodium sulphide T.S., the liquid must possess a distinct odor of ammonia, and the two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter) (*lead*).

"**Assay.**—Proceed as directed under the Assay for alkali salts of organic acids (see Part III, Test No. 6). It shows not less than 73.72 per cent. nor more than 77.39 per cent. of $KNaC_4H_4O_6$.

"Each mil of half-normal sulphuric acid V.S. used corresponds to 0.05253 Gm. of $KNaC_4H_4O_6$. Each gramme of Potassium and Sodium Tartrate corresponds to not less than 14.03 mils nor more than 14.73 mils of half-normal sulphuric acid V.S." *U. S.*

"Trimetric prisms with hemihedral facets. Taste saline, cooling. Soluble in 1.5 parts of *water;* aqueous solution neutral to *litmus*. Yields the reactions characteristic of potassium, of sodium, and of tartrates. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 13.9 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, iron, calcium, ammonium, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 2 parts per million." *Br.*

When the salt is exposed to a very strong heat, it becomes blackened, and gives out inflammable gases with the odor of burnt sugar, the tartaric acid being destroyed, and a mixture of potassium and sodium carbonates left. It sometimes contains calcium tartrate, which may be removed by solution and crystallization, but when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with nearly all acid salts except potassium bitartrate. It is also decomposed by lead acetate and subacetate, silver nitrate, and by the soluble calcium and barium salts unless the solution of the tartrate be considerably diluted.

The way in which the acids act in decomposing potassium and sodium tartrate is by combining with the sodium, and throwing down potassium bitartrate as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle, and hence is frequently called *Seignette's salts* or *Rochelle salt.*

Uses.—This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the mildest and least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders. (See *Pulvis Effervescens Compositus.*) When given in small and repeated doses it usually does not act as a purgative, but is absorbed and renders the urine alkaline. (Millon and Laveran, *J. P. C.,* 3e sér., vii, 222.)

Potassium and magnesium tartrate, formed by saturating cream of tartar with magnesium carbonate, has been proposed by Maillier for use as a safe, pleasant purgative.

Dose, as a purge, from half an ounce to an ounce (15.5–31 Gm.).

Off. Prep.—Pulvis Effervescens Compositus, *U. S.* (*Br.*).

POTASSII HYDROXIDUM. U. S. (Br.)

POTASSIUM HYDROXIDE Pot. Hydrox. [Potassium Hydrate, Caustic Potash, Potassa, U. S. 1890]

(pŏ-tăs'sĭ-ī hȳ-drŏx'ĭ-dŭm)

"It contains not less than 85 per cent. of KOH (56.11). Preserve it in well-closed containers. If bottles are used they must be made of hard glass." *U. S.* "Potassium Hydroxide may be obtained by the interaction of potassium carbonate and calcium hydroxide. It contains not less than 85 per cent. of pure potassium hydroxide, KOH." *Br.*

"Take of Solution of Potash, *two pints* [Imperial measure]. Boil down the Solution of Potash rapidly in a [clean] silver vessel, until there remains a [clear] fluid of oily consistence, a drop of which when removed on a warm glass rod solidifies on cooling. Pour this into proper moulds, and when it has solidified, and while it is still warm, put it into stoppered bottles." *Br.,*

1885. A process for potassium hydroxide is no longer in the U. S. Pharmacopœia; that of 1870 is identical with the British (1885).

The solid alkali obtained from these processes is potassium hydroxide, sufficiently pure for medicinal purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula (see *Liquor Potassii Hydroxidi*), the formation of the present salt requires merely the evaporation of this solution until nearly the whole of its uncombined water is driven off. The evaporation must be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali, and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb carbon dioxide from the atmosphere. When poured out on a metallic plate or dish, the cake, just as it solidifies, may be marked with a knife in the direction in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the former U. S. and British formulas. These should be made of silver or iron and have a cylindrical shape, which is the most convenient form of the alkali for surgical use. Green glass bottles with rubber stoppers are best adapted for preserving this preparation, as white flint glass is attacked by the alkali. Potassium hydroxide is now prepared at Niagara Falls, N. Y., by the electrolysis of strong potassium chloride solution. The metal at the cathode acts with water to form potassium hydroxide and free hydrogen, while chlorine is liberated at the anode, and is used in making bleaching powder which is thus prepared simultaneously.

Properties.—It is officially described as in "dry, white, or nearly white, fused masses, or sticks, hard and brittle, showing a crystalline fracture; odorless. *Great caution is necessary in handling it,* as it rapidly destroys organic tissues. When exposed to the air, it readily absorbs carbon dioxide and moisture, and deliquesces. One Gm. of Potassium Hydroxide dissolves in 0.9 mil of water, about 3 mils of alcohol, and in 2.5 mils of glycerin at 25° C. (77° F.); also in 0.6 mil of boiling water; very soluble in boiling alcohol. An aqueous solution of Potassium Hydroxide even when greatly diluted is strongly alkaline to litmus. When introduced into a non-luminous flame, it imparts to it a violet color. An aqueous solution of Potassium Hydroxide (1 in 20) is clear and colorless (*organic matter or insoluble impurities*). An aqueous solution of Potassium Hydroxide (1 in 10), when added to an excess of tartaric acid T.S., produces a white, crystalline precipitate, which redissolves when the Potassium Hydroxide is added in excess. An aqueous solution of Potassium Hydroxide (1 in 50), slightly acidulated with hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dissolve in a 500 mil graduated flask about 10 Gm. of Potassium Hydroxide, accurately weighed in a glass-stoppered weighing-bottle, in 250 mils of distilled water, which has previously been boiled and cooled, and add 30 mils of barium chloride T.S. Now fill the flask to the mark with distilled water, which has previously been boiled and cooled, and thoroughly agitate the liquid. Then filter the liquid in the flask through a dry filter into a dry flask, rejecting the first 20 mils, and titrate 200 mils of the clear filtrate with normal hydrochloric acid V.S., using phenolphthalein T.S. as indicator. It shows not less than 85 per cent. of KOH when calculated to the amount originally taken.

"Each mil of normal hydrochloric acid V.S. used corresponds to 0.05611 Gm. of KOH. Each gramme of Potassium Hydroxide corresponds to not less than 15.15 mils of normal hydrochloric acid V.S." *U. S.*

"In hard white pencils or cakes, very deliquescent, very alkaline and corrosive. Soluble in 0.5 part of *water,* and in 3 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium. 1 gramme dissolved in *water* or in *alcohol* (90 per cent.) leaves only a slight sediment; the solution requires for neutralisation not less than 15.1 millilitres of *N/1 solution of sulphuric acid.* Yields no characteristic *reactions* for lead, copper, or arsenic." *Br.*

It is important that the requirements of the Pharmacopœia be complied with, and that it should contain not less than 85 per cent. of pure potassium hydroxide.

The *white stick caustic potassa* as found in commerce usually contains from 15 to 28 per cent. of water, which seems to be a necessary impurity, for if a certain quantity of water is not present it is impossible to mould the stick. By heating this so as to drive off the water a purified hydroxide in cakes may be obtained. On account of its deliquescent property, and its strong attraction for carbon dioxide, potassium hydroxide requires to be kept in very accurately stoppered bottles. Official potassium hydroxide may be rendered nearly pure by digestion in alcohol, which takes up only the alkaline hydroxide, evaporating the solution to dryness, and fusing the dry mass obtained. *Potassium hydroxide,* when thus procured, is called *potash by alcohol.* It is generally in flat white pieces, which are dry, hard, brittle, and extremely caustic. Its other properties are similar to those of the impure hydroxide above described. According to H. Wurtz, of New York, commercial potash by alcohol usually contains a trace of potassium silicate, which appears to be taken up by the alcohol. The source of this is the potassium carbonate employed, which may be freed from this impurity by evaporating its aqueous solution, in a sheet iron dish, to dryness, and adding, from time to time, lumps of ammonium carbonate. The silicate is thus converted into the carbonate, and on dissolving the residue the silica appears in flakes, which may be separated by filtration. Potassium hydroxide may be distinguished from the other fixed alkalies (soda and lithia) by its affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric

acid, and a yellow one with platinic chloride. Potassium hydroxide imparts to the flame of burning alcohol in which it is dissolved a lilac tint; sodium hydroxide colors it yellow even in the presence of potassium hydroxide; and thus a method is afforded of detecting an admixture of the latter with the former alkali. According to Bunsen, when the flame is viewed through a glass having a cobalt-blue color, only the color imparted by potassium is seen, the yellow color of the sodium flame being absorbed by the blue glass. (*J. P. C.*, Oct., 1860, p. 319.) Potassium hydroxide, KOH, is composed of one atom of potassium, united with one hydroxyl group, OH.

Uses.—Probably because of its powerful effect in dissolving the bodily tissues potassium hydroxide is a very potent escharotic. It is the old *causticum commune acerrimum* or *strongest common caustic.* (For description of potassa with lime which was formerly official, see *U. S. Dispensatory,* 19th edition, page 1004.) Its action is not only very thorough, but it penetrates more deeply than either silver nitrate or nitric acid. It is also powerfully germicidal; although Sternberg found that it required a ten per cent. solution to destroy pus cocci in two hours, most authorities agree that one per cent. is sufficient to kill all vegetating bacteria. Because of difficulty of controlling its action it is not commonly employed for the destruction of benign growths as *warts,* but in *poisoned bites,* especially by *rabid animals,* the thoroughness of its action is an advantage.

The most convenient mode of employing the caustic for the formation of an issue is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its center corresponding with the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end. The application is to be continued until the life of the part is destroyed, when the caustic should be carefully washed off with a wet sponge, or wet towl, or neutralized by vinegar. In forming from it solutions of potassium hydroxide of definite strength, whether for medicinal or for pharmaceutical use, an allowance should be made for the percentage of water it always contains. (See *Liquor Potassii Hydroxidi.*)

Off. Prep.—Liquor Potassii Hydroxidi, *U. S.* (*Br.*); Liquor Picis Alkalinus, *N. F.*; Potassa cum Calce, *N. F.*

POTASSII HYPOPHOSPHIS. U. S.

POTASSIUM HYPOPHOSPHITE Pot. Hypophos.

(pŏ-tā'sĭ-ī hī-pŏ-phŏs'phĭs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 98 per cent. of KPH_2O_2 (104.16). Preserve it in well-closed containers in a dry place. Caution should be observed in dispensing Potassium Hypophosphite, as an explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents." *U. S.*

Kali Hypophosphorosum, Hypophosphis Potassicus, s. Kalicus; Hypophosphite de Potasse, *Fr.*; Unterphosphorigsaures Kali, *G.*

This salt is prepared by mixing solutions of calcium hypophosphite and granulated potassium carbonate, in the proportion of 6 ounces of the former dissolved in four pints of water to 5.75 ounces of the latter in half a pint. As a result of double decomposition between the two salts, calcium carbonate and *potassium hypophosphite* are formed, the former being precipitated, and the latter held in solution.

$$Ca(H_2PO_2)_2 + K_2CO_3 = CaCO_3 + 2KH_2PO_2$$

The calcium carbonate is removed by filtration, and the clear solution is evaporated until a pellicle forms, after which it is constantly stirred, with continuance of the heat, until the salt granulates. The heat employed in the evaporation should be kept considerably below 100° C. (212° F.), for fear of explosion. If the salt be required pure, it should be dissolved in the granulated state, in official alcohol, and the solution evaporated to a syrupy consistence and then set aside to crystallize. The calcium hypophosphite may be prepared by a formula given under the head of *Calcii Hypophosphis.*

Properties.—"Potassium Hypophosphite occurs as white, opaque, hexagonal plates, or crystalline masses, or as a granular powder; odorless, and having a pungent, saline taste; very deliquescent. One Gm. of Potassium Hypophosphite dissolves in 0.6 mil of water and in 9 mils of alcohol at 25° C. (77° F.); also in 0.4 mil of boiling water and in 5 mils of boiling alcohol. An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus and yields with sodium bitartrate T.S. a white, crystalline precipitate. When heated in a dry test tube spontaneously inflammable hydrogen phosphide is evolved which burns with a bright yellow flame. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added drop by drop with agitation to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Potassium Hypophosphite, the precipitate becomes gray from reduction to metallic mercury. A solution of 1 Gm. of the salt in about 10 mils of distilled water requires not more than 1.5 mils of tenth-normal hydrochloric acid V.S. for neutralization, methyl orange T.S. being used as indicator. Heat 5 mils of an aqueous solution of the salt (1 in 5) with 0.5 mil of diluted hydrochloric acid in a test tube on a water bath for thirty minutes; no offensive odor is developed. Measure 5 mils of an aqueous solution of Potassium Hypophosphite (1 in 25) into a beaker containing 3 mils of nitric acid diluted with about 10 mils of distilled water, and evaporate the mixture to dryness on a water bath; the residue meets the requirements

of the Test for arsenic (see Part III, Test No. 1). Add magnesia mixture T.S. to 10 mils of an aqueous solution of the salt (1 in 20) made alkaline with ammonia water; it is not affected within one minute (*phosphates*).

"**Assay.**—Dissolve about 1 Gm. of Potassium Hypophosphite, dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 10 mils of distilled water, add 10 mils of nitric acid and evaporate it to dryness on a water bath. Then add 5 mils of nitric acid and again evaporate it to dryness on a water bath. Dissolve the residue in 20 mils of distilled water, add a drop of phenolphthalein T.S. and sufficient special potassium hydroxide T.S. (see page 545) to produce a pink color, and then dilute it to exactly 100 mils with distilled water. Transfer 10 mils of this solution to a 100 mil graduated flask, add 50 mils of tenth-normal silver nitrate V.S. and proceed from this point as directed in the assay under *Sodii Phosphas* (see page 1036). When calculated to the amount originally taken, it shows, in the dried salt, not less than 98 per cent. of KPH_2O_2.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.003472 Gm. of KPH_2O_2. Each gramme of Potassium Hypophosphite, previously dried, corresponds to not less than 282.3 mils of tenth-normal silver nitrate V.S." *U. S.*

Uses.—This salt was introduced along with the other hypophosphites because of the claims made by Churchill of their curative value in *phthisis* (see *Acidum hypophosphorosum*), but has no therapeutic virtues justifying its continued recognition by the Pharmacopœia.

Dose, ten to thirty grains (0.65–2.0 Gm.).

POTASSII IODIDUM. U. S., Br.

POTASSIUM IODIDE Pot. Iod.

(pŏ-tăs'sĭ-ī ī-ŏd'ĭ-dŭm)

"It contains, when dried to constant weight at 100° C. (212° F.), not less than 99 per cent. of KI (166.02). Preserve it in well-closed containers." *U. S.* "Potassium Iodide may be obtained by adding a slight excess of iodine to a strong solution of potassium hydroxide, evaporating to dryness, fusing with charcoal, and purifying by crystallisation. When dried at 100° C. (212° F.) it contains not less than 99 per cent. of pure potassium iodide, KI." *Br.*

Iodide of Potassium; Potassii Hydriodas; Kali Hydriodicum, Ioduretum Potassicum, s. Kalicum; Iodure de Potassium, *Fr. Cod.;* Kalium Jodatum, *P. G.;* Kaliumjodid, Jodkalium, *G.;* Joduro di potassio, *It.;* Yoduro potasico, *Sp.*

No process is given in the U. S. or Br. Pharmacopœias. That of the U. S. P., 1870, did not differ essentially from the British, 1885. (See *U. S. Dispensatory,* 19th edition, page 1005.)

An aqueous solution of potassium hydroxide is treated with iodine in slight excess. The result of thus saturating potassium hydroxide with iodine is the formation of two salts, *potassium iodide and iodate.* Six atoms of iodine react with six molecules of potassium hydroxide, and there are formed five molecules of potassium iodide and one of potassium iodate,

$$6KOH + 3I_2 = 5KI + KIO_3 + 3H_2O$$

By evaporating the solution to dryness the mixed salts are obtained, and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide, thus removing this impurity from the iodide. In the formula the mixed salts, towards the close of their evaporation to dryness, are directed to be mixed with powdered charcoal, according to the plan of Scanlon, which facilitates the deoxidation of the iodate.

$$KIO_3 + 3C = KI + 3CO$$

This being accomplished by a dull red heat, the potassium iodide is dissolved out of the mass, and the solution is set aside to crystallize.

In the older processes the first step was to form ferrous iodide in solution, precisely as is done in the formula for that compound, and the second to decompose it by potassium carbonate, which gave rise to potassium iodide in solution, and a precipitate of ferrous carbonate. The solution of potassium iodide was separated by filtration and washing from the precipitated carbonate, and evaporated to dryness. The dry salt was then freed from iron and other impurities by solution in boiling water or alcohol, filtration, and crystallization. This method is analogous to that described under potassium bromide, which see. An improvement on this process is to add enough iodine to the ferrous iodide solution first formed to produce ferrous-ferric iodide, $Fe_3I_8(2FeI_3 + FeI_2)$. This solution is now treated with an equivalent quantity of potassium carbonate and boiled when ferrous-ferric oxide precipitates, carbon dioxide escapes, and all the iodine goes into solution as iodide, the reaction being:

$$Fe_3I_8 + 4K_2CO_3 = Fe_3O_4 + 8KI + 4CO_2$$

According to the method of E. Sonstadt, potassium iodide is prepared directly from the mother liquors of kelp by converting the alkaline iodides into iodates by means of chlorine or potassium permanganate, precipitating the iodic acid by a soluble barium salt, heating the precipitate with solution of potassium sulphate, evaporating the resulting potassium iodate solution to dryness, and crystallizing from its solution the potassium iodide thus obtained. (*Chem. News,* xxvi, 182.) Or, these mother liquors are evaporated to dryness, the mass gently roasted to oxidize sulphides, and then extracted with water, evaporated again to dryness and extracted with alcohol, whereby sodium and potassium iodide go into solution. This is treated

with potassium carbonate to change the sodium iodide into potassium iodide, and a stream of CO_2 led through to precipitate the sodium bicarbonate. The remaining solution contains potassium iodide with a little sodium bicarbonate. (Flückiger, *Pharm. Chem.*, 2d ed., 1888, p. 341.) Large quantities are now manufactured from the cuprous iodide coming from the South American sodium nitrate works. The cuprous iodide is suspended in water acidified with hydrochloric acid, and a stream of hydrogen sulphide gas let in, whereby hydrogen iodide enters into solution. This solution is filtered, neutralized with potassium carbonate, and evaporated to crystallization.

$$CuI_2 + H_2S = CuS + 2HI$$
$$2HI + K_2CO_3 = 2KI + H_2O + CO_2$$

Properties.—Potassium iodide, sometimes incorrectly called *hydriodate of potassa*, is in "cubical crystals either transparent and colorless or more or less opaque and white, or as a white, granular powder, having a pungent, saline, afterwards bitter taste. Permanent in dry air, and but slightly deliquescent in moist air. One Gm. of Potassium Iodide dissolves in 0.7 mil of water, 22 mils of alcohol, and in 2 mils of glycerin at 25° C. (77° F.); also in 0.5 mil of boiling water and in 8 mils of boiling alcohol. An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus. When heated, the salt decrepitates. At a low red heat it fuses, and at a bright red heat it is volatilized without decomposition. Five mils of an aqueous solution of Potassium Iodide (1 in 20) yields a white, crystalline precipitate with 5 mils of sodium bitartrate T.S. Add 1 mil of ferric chloride T.S., diluted with an equal volume of distilled water, to 5 mils of an aqueous solution of the salt (1 in 20), and shake the mixture with 5 mils of chloroform; the latter acquires a violet color. Dissolve 1 Gm. of the salt in 10 mils of distilled water and add 0.1 mil of tenth-normal sulphuric acid V.S.; no color is produced by the subsequent addition of a drop of phenolphthalein T.S. (*alkali*). Add 2 drops of diluted sulphuric acid (free from sulphurous and nitrous acids) to 0.5 Gm. of the salt dissolved in 10 mils of distilled water, which has previously been boiled and cooled; no distinct yellow color appears within half a minute (*iodate*), and no turbidity occurs (*thiosulphate*). Acidulate 10 mils of an aqueous solution of the salt (1 in 20) with hydrochloric acid; it is not rendered turbid by the addition of 1 mil of potassium sulphate T.S. (*barium*); another 10 mil portion of an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is not rendered more than slightly turbid by a few drops of barium chloride T.S. (*sulphate*). Heat gently 5 mils of an aqueous solution of the salt (1 in 10) with one drop of ferrous sulphate T.S. and 0.5 mil of potassium hydroxide T.S.; no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*). An aqueous solution of the salt does not respond to the Test for heavy metals (see Part III, Test No. 3).

"**Assay.**—Dry the salt to constant weight and proceed as directed under the Assay for iodides (see Part III, Test No. 5). It shows, in the dried salt, not less than 99 per cent. of KI.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.016602 Gm. of KI. Each gramme of Potassium Iodide, previously dried, corresponds to not less than 59.6 mils nor more than 61.0 mils of tenth-normal silver nitrate V.S." *U. S.*

"Colorless, generally opaque, cubic crystals. Taste saline, slightly bitter. Soluble in less than 1 part of *water*, and in 12 parts of *alcohol* (90 per cent.). Usually slightly alkaline to *litmus*. Yields the *reactions* characteristic of potassium and of iodides. Loses not more than 1 per cent. of its weight when dried at 100° C. (212° F.); 0.5 gramme of this dried salt requires for complete precipitation not less than 29.8 nor more than 30.5 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for copper, iron, aluminium, calcium, magnesium, bromates, cyanides, or nitrates, and not more than the slightest reactions for bromides, iodates, carbonates, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

According to T. and H. Smith, of Edinburgh, it is not at all deliquescent when perfectly pure. It generally crystallizes in cubes. If solution of potassium iodide be mixed with solution of starch, and a minute quantity of solution of chlorine be added, a blue color will be produced, the chlorine combining with the potassium liberating the iodine, which forms a blue compound with starch.

R. Van Vorst has pointed out (*Ph. Ztg.*, 1914, p. 342) that the red spots seen sometimes upon crystals of potassium iodide are not always due to free iodine, as in a case which he investigated the salt dissolved to a colorless solution leaving an insoluble red precipitate, which upon closer investigation was found to be the cell structure of a microscopic form of mold.

Its solution is quickly decomposed by the addition of a few drops of sulphuric acid, hydriodic acid being generated, which speedily undergoes decomposition, with evolution of iodine, and, if starch be added after the lapse of a few minutes, a blue color will be produced. The starch test will not give the characteristic blue color immediately, if added simultaneously with the acid, unless the potassium iodide contains potassium iodate, which impurity causes an immediate liberation of iodine. The blue color being produced by the starch and acid, if simultaneously added, is, therefore, a sign of impurity. Hydrogen dioxide solution may be used in this test as it causes the liberation of free iodine from soluble iodides. A very delicate test for potassium iodide and other soluble iodides is that of Grange. It consists in pouring a little of the liquid to be examined into a test tube, adding a few drops of solution of starch, and passing through the mixture a few

bubbles of fuming nitrous acid. The liquid immediately assumes a pale rose color, inclining to violet, if containing 1-200,000th of its weight of the iodide, and a bright blue color if 1-100,000th is present. (See page 591.) When tartaric acid is freely added to a strong solution of the iodide, it occasions a white crystalline precipitate, and the supernatant liquid, if mixed with starch, becomes first purple, and finally blue. The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid of a deep brown color.

Payen has noticed a curious effect produced by potassium iodide. In saturated solution, this salt causes in starch added to it an enlargement of its granules to twenty-five or thirty times their original volume, dissolving the interior substance of the granules, and enormously distending the exterior layer. Potassium bromide produces the same effect, but the alkaline chlorides cause neither the enlargement referred to, nor a solution of the amylaceous substance, and if the saturated solution of the iodide be diluted with three and a half volumes of water or more, it is inert in reference to starch in the cold. (*J. P. C.*, 4e sér., ii, 373.) Ferières found that ether added to a solution of potassium iodide decomposes it, but it was stated by the researches of de Vrij and of Magnes-Lahens that this does not happen with pure ether, but is due to the acetic acid which is developed by sunlight in ether. (*J. P. C.*, 4e sér., xvi, 107, 468; xvii, 116.) This change is now known to be due to minute amounts of peroxide which are present in ether which has been exposed to air.

Exposed to a dull red heat, potassium iodide fuses, and on cooling concretes into a crystalline pearly mass, without loss of weight; but at a full red heat it is slowly volatilized without decomposition. The most usual impurities contained in this salt are potassium and sodium chlorides, potassium bromide, and potassium carbonate and iodate. Potassium iodide, to conform to the U. S. P. IX, must contain 99 per cent. of the pure salt.

The low price of potassium bromide, compared with that of the iodide, has caused the former to be used for the adulteration of the latter. When potassium bromide is sold for the iodide, the fraud may be detected by the fact that the addition of sulphuric acid produces copious reddish fumes, instead of the purple ones arising from the iodide. A very delicate test for bromide in iodide is based upon the different actions of iodide and bromide with lead dioxide. This reagent will liberate iodine from iodide on boiling, but will not decompose any bromine by boiling. Therefore, after the suspected sample has been boiled with the lead dioxide until all the iodine is driven off, and then filtered, the filtrate may be treated with fresh dioxide and a little acetic acid, when any bromine present is decomposed, and the free bromine will color carbon disulphide or answer other tests. (Flückiger, *Pharm. Chem.*, 2d ed., 1888, p. 350.)

In order to detect bromine, Personne first precipitated from an aqueous solution of the suspected iodide the whole of the iodine as cuprous iodide, by successively adding, in excess, a solution of copper sulphate and aqueous sulphurous acid, and then treats the filtered liquid with ether and chlorine water, the whole being shaken together and left at rest. If bromine be present, the ether which rises to the surface will be tinged of a reddish-yellow color. Fresenius's test of gold chloride is, according to J. H. Bill, of the U. S. Army, very delicate. The iodine having been separated by palladium, and the excess of palladium by hydrogen sulphide, the solution supposed to contain bromine, if treated first with a drop of hydrochloric acid, and then with a drop of solution of gold chloride, will, if bromine be present, exhibit a decided yellowness, which will appear more obviously if the solution be compared with pure water or a weak solution of a chloride. (See *A. J. P.*, 1868, 272.) Potassium carbonate may be detected by lime water, which causes a milkiness (calcium carbonate), and by tincture of iodine, the color of which is destroyed. The iodate may be detected by adding a solution of tartaric acid to a solution of the suspected iodide. Potassium bitartrate will be precipitated, and, if the iodide be pure, a yellow color will, *after a short time,* be developed by the action of the air on the liberated hydriodic acid; but if any iodate be present the test will give rise to both iodic and hydriodic acids, which, by their mutual action, will *instantly* develop iodine.

According to Payen, a saturated solution of potassium iodide, which will evince signs of decomposition by becoming orange-yellow, in the presence of atmospheric air, on the addition of small quantities of acetic, nitric, oxalic, and probably many other acids, remains unaffected by these additions if atmospheric air be excluded. It was first pointed out by Loew (*A. J. P.*, xlii, 80), and afterwards confirmed by Vidau in an elaborate series of experiments, that iodine is liberated from a solution of potassium iodide by direct sunlight; the more concentrated the solution the more energetic is the action. (*J. P. C.*, 4e sér., xx, 351.)

Potassium iodide is incompatible with a few alkaloids, calomel, mercurous and mercuric oxides, turpeth mineral, white precipitate, blue mass, and metallic mercury. Melsens observed that potassium iodide given in connection with the insoluble preparations of mercury rendered them soluble and much more active. (See *A. J. P.*, xxvi, 222.) With nitrous ether potassium iodide reacts, yielding, among other products, ethyl iodide and a little ordinary ether. (Juncadella, *C. R. A. S.*, Fév., 1859, p. 345.) At ordinary temperatures potassium iodide is slowly decomposed, with evolution of iodine, by ammonium nitrate or boric acid, and at high temperatures, in a glass test tube, with escape of violet vapors, not only by the two substances just named, but also by ammonium sulphate, oxalate, carbonate, and chloride, sodium sulphate, phosphate, nitrate, and borate, potassium and magnesium sulphates, calcium nitrate,

sodium, potassium, and calcium chlorides, and silicic acid. (Ubaldini, *J. P. C.*, Oct., 1859, p. 292.) Melsens has noticed another very important fact in relation to the operation of potassium iodide. When this salt and potassium chlorate are mixed in solution, no change takes place at ordinary temperatures; but if a certain amount of a mineral acid be added to the solution of the mixed salts, a reaction occurs, attended with the escape of iodine, and evidences are presented of the existence of iodic acid in the solution. Now, Melsens has ascertained by experiments on dogs that neither of these salts, if given separately and at different times, produces an evil effect, while if given together, so as to be in the system at the same time, they act as a poison, and may cause death in a few days. Seven grammes (108 grains) of a mixture of potassium iodide and potassium chlorate, in equivalent proportions, given daily to a dog of medium size, uniformly proved fatal in less than a month, and often as early as the fifth day. Melsens ascribed the result to the production of potassium iodate, which he has shown to be a poisonous salt. (*A. J. P.*, Nov., 1866, p. 521; from *Bull. Soc. Chim.*) With certain alkaloids potassium iodide is incompatible, partly on account of the fact that it is permitted to contain a little alkaline carbonate to retard discoloration, and partly because with some alkaloids insoluble iodides are formed, and fatal results have been caused by the strychnine iodide crystallizing out of a prescription, so that the whole of it was taken at a single dose.

Uses.—The general therapeutic properties of potassium iodide are the same as those of iodine. (See page 591.) Like the other salts of this element, potassium iodide is useful especially in *syphilis, chronic fibrinous inflammations,* and certain *metallic poisons.* With corrosive sublimate it forms a soluble potassio-mercuric iodide which is the basis of the so-called *mixed treatment* for *syphilis.* When it is administered in large repeated doses it produces evidences of systemic affection, known as *iodism.* The most usual indication of its constitutional action is a pain over the brow, with coryza; in some cases a mild ptyalism, with fetor of the breath and slight swelling of the gums, is produced. In a number of cases it causes an eruption, sometimes simply of macula, but usually of acne and occasionally bullous or hemorrhagic. In unusual conditions of the system these skin affections may become very severe and ulcerations result. Knowles (*J. A. M. A.*, 1910, lv, p. 100) gives an extensive bibliography of the literature of this subject.

The dose of potassium iodide varies enormously, many persons will show symptoms of iodism from twenty grains (1.3 Gm.) a day, but other cases as much as one or two drachms (3.9–7.7 Gm.) have been given three times a day without toxic symptoms. Many clinicians believe that syphilitics are abnormally tolerant of the drug.

Potassium iodide is eliminated through the urine unchanged and may be detected by acidulating with nitric acid which causes the liberation of the free iodine, and by testing with starch.

Potassium iodide is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodi.*)

Dose, five to twenty grains (0.32–1.3 Gm.); in special cases much larger doses may be exhibited.

POTASSII NITRAS. U. S., Br.

POTASSIUM NITRATE Pot. Nit.
[Nitre Saltpetre]

(pŏ-tăs'sĭ-ī nī'trās)

"In contains, when dried to constant weight at 100° C. (212° F.), not less than 99 per cent. of KNO_3 (101.11). Preserve it in well-closed containers." *U. S.* "Potassium Nitrate, KNO_3, may be obtained by the interaction of sodium nitrate and potassium chloride." *Br.*

Potassæ Nitras; Nitrum Depuratum, Sal Petræ, s. Nitri, Nitras Potassicus, s. Kalicus; Nitrate of Potash, Nitre; Nitrate de Potasse, Azotate de Potasse, *Fr. Cod.;* Nitre prismatique, Salpêtre, *Fr.;* Kalium Nitricum, *P. G.;* Kaliumnitrat, Salpetersaures Kali, Salpeter, Kalisalpeter, *G.;* Nitrato di potassio, Nitro, *It.;* Nitrato potasico, *Sp.*

Potassium nitrate or *nitre,* is both a natural and an artificial product. It occurs in many countries, existing in the soil, on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in South Africa, in Egypt, and in Chili, Peru and Bolivia, but the country in which it has been most largely produced is India. In the United States it has been found in caverns situated in limestone rock, called saltpetre caves, where it is associated with calcium nitrate. A large proportion of the potassium nitrate consumed in the South, during the Civil War was obtained from such caves in Kentucky. Considerable deposits also occur in San Bernadino County in California, but have not been developed as yet (1916). At present it is chiefly obtained from deposits in India, or by acting on sodium nitrate with potassium chloride. Potassium nitrate exists also in the vegetable kingdom, having been found in tobacco, borage, bugloss, parietaria, hemlock, and the sunflower. The artificial sources are certain mixtures of animal and vegetable substances with wood ashes and calcareous matter, called nitre-beds, and certain materials impregnated with saltpetre, consisting principally of plaster rubbish, derived from the demolition of old buildings. The ashes of tobacco stems, consisting almost exclusively of potassium carbonate and chloride, have been proposed by Commaille as an artificial source of potassium

nitrate by adding them to the ordinary nitre-beds. (*J. P. C.*, Fév., 1856.)

The nitrifying bacteria, usually *B. nitrificans*, so common in nature, acting over a period of one or two years, which is necessary for these artificial nitre beds, form calcium nitrate first, which then reacts with the potassium carbonate of the wood ashes to form potassium nitrate, according to the following reaction:

$$Ca(NO_3)_2 + K_2CO_3 = 2KNO_3 + CaCO_3$$

Preparation from its Natural Sources.—In India the saline earth, which contains about seven parts of potassium nitrate in a thousand, is lixiviated in large mud filters lined with stiff clay, and furnished with false bottoms of bamboo, covered with grass mats, on which wood ashes are laid. The filters being then filled with the saline earth, water is added, and the solution filters through the wood ashes, with the effect of converting the calcium nitrate present, amounting to nearly 1 per cent., into potassium nitrate. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure potassium nitrate thus obtained contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized, and thrown into commerce under the name of crude saltpetre. Besides the nitre obtained in India by the filtration of the soil deposited during the overflow of the Ganges, it appears, from the report of J. W. Palmer, that much of the crude salt is procured, in the northwestern provinces of Hindostan, from the saline incrustations formed in and around the mud walls surrounding the dwellings of the natives. The scrapings from these sources are lixiviated, and the impure solution allowed to evaporate in shallow pans exposed to the sun. The impure nitre extracted from the earthy matters crystallizes out, while from 1 to 9 per cent. of sodium chloride remains in the mother liquor, and is recovered by evaporation. (*A. J. P.*, 1868, 436.) *Juar*, a plant used in India as fodder, contains in its stems during dry seasons a large quantity of potassium nitrate (17 per cent.); when in this condition it is poisonous to animals. (*P. J.*, 1896, 380.)

Within recent years potassium nitrate has been most largely manufactured from the native potassium chloride of Stassfurt and the native sodium nitrate of Chili, two cheap and abundant crude materials, which by their reaction yield potassium nitrate. For this purpose equal molecular quantities of the two salts are dissolved in water with the aid of heat until the specific gravity of the liquor reaches 1.5. The resulting sodium chloride, being less soluble in hot water, is precipitated, and the solution on cooling and agitation deposits the saltpetre as a fine powder. This so-called "conversion saltpetre" can be produced 99.9 per cent. pure nitrate.

Artificial Preparation.—Since the importations from Germany have been interrupted in 1914, the search for new sources of supply in the United States has been pushed actively. The chief sources so far developed are: the sea kelp from the Pacific coast, containing as much as 2.45 per cent. of K_2O; *alumite*, a natural hydrated double sulphate of potassium and aluminum found in southern Utah; certain lakes in Nebraska containing salines relatively rich in potassium chloride; flue dust from cement works and from blast furnaces, both of which yield soluble potash salts. *Artificial nitre beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter the mixture from the rain, while the sides are left open, to admit the free access of air. The mixture is disposed in little rangse or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by reacting with the potassium compounds existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown color, and contains chiefly potassium nitrate, but at the same time more or less of calcium and magnesium nitrates and of sodium chloride. The earthy nitrates are then decomposed by a solution from wood ashes, the potassium carbonate of which converts them into nitre and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The solution is then allowed to cool, and the nitrate crystallizes in dirty-white crystals, called crude nitre. Calcium nitrate may be converted into nitre by adding it to a solution of potassium sulphate. Calcium sulphate is precipitated, and potassium nitrate remains in solution.

Theory of Nitrification.—The continuous formation of nitre in nitre earths and in artificial nitre beds result from the oxidation of the nitrogen of ammonia, thus generating nitric acid, the formation of which is facilitated by the presence of alkaline and earthy bases, with which the acid unites, but in reality depends upon the presence of nitrifying micro-organisms (*Bacillus nitrificans*), so that nitrification is not strictly an oxidation process, as was at one time supposed. The ammonia is derived, for the most part, from the organic remains in the nitre earths, and from the animal matter which is an essential ingredient in the artificial mixtures. According to Schoenbein, whose statement has been confirmed by Goppelsröder, the formation of the nitric acid is always preceded by that of nitrous acid.

Purification.—Potassium nitrate, as first obtained, either from natural or from artificial

sources, is called in commerce crude saltpetre, and requires to be purified before it can be used in medicine or in most of the arts. The process, which is founded principally on the fact that nitre is more soluble than common salt in hot water, is conducted in France as follows: Thirty parts of saltpetre are boiled with six parts of water, and the portion which remains undissolved or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added, at intervals, until the whole, including that previously added, amounts to ten parts. The clear solution is now transferred to large, shallow copper coolers, where it is agitated with wooden instruments to hasten the cooling and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper with holes in the bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, after which it is permitted to drain off by taking out the pegs. The salt is now dried, and takes the name of purified nitre.

Properties.—Potassium nitrate occurs "as colorless, transparent, six-sided rhombic prisms, or a white, crystalline powder; odorless, having a saline taste and producing a cooling sensation in the mouth. Slightly hygroscopic in moist air. One Gm. of Potassium Nitrate dissolves in 2.8 mils of water and in 620 mils of alcohol at 25° C. (77° F.); also in 0.5 mil of boiling water; soluble in glycerin. Its aqueous solution (1 in 10) is neutral to litmus. When strongly heated, the salt melts without decomposition. At higher temperatures it evolves oxygen and is partly reduced to nitrite. When Potassium Nitrate is heated with charcoal, the mixture deflagrates. With sodium bitartrate T.S. an aqueous solution of the salt (1 in 20) yields a white crystalline precipitate. Mix an aqueous solution of Potassium Nitrate (1 in 10) in a test tube with a drop of diphenylamine T.S. and slowly add sulphuric acid so as to form a separate layer; a deep blue color appears at the line of contact. An aqueous solution of Potassium Nitrate does not respond to the Test for heavy metals (see Part III, Test No. 3). No yellow color appears when 0.1 Gm. of the dry salt is sprinkled upon 1 mil of concentrated sulphuric acid (*chlorate or perchlorate*).

"**Assay.**—Dissolve about 0.4 Gm. of Potassium Nitrate, previously dried to constant weight at 100° C. (212° F.) and accurately weighed, in 10 mils of hydrochloric acid in a small dish, and evaporate the solution to dryness on a water bath. Dissolve the residue in 10 mils of hydrochloric acid and again evaporate it to dryness on a water bath, continuing the heat until the residue, when redissolved in distilled water, is neutral to litmus. Transfer the residue with the aid of 25 mils of distilled water to a flask and proceed as directed under the Assay for chlorides (see Part III, Test No. 5), deducting from the amount of tenth-normal silver nitrate V.S. consumed, the amount which would be consumed by the chlorides present in an equivalent weight of the salt originally taken, and previously estimated by taking about 1 Gm. of the salt, accurately weighed, and proceeding as directed under the Assay for chlorides (see Part III, Test No. 5). It shows, in the dried salt, not less than 99 per cent. of KNO_3. Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.010111 Gm. of KNO_3. Each gramme of Potassium Nitrate, previously dried, corresponds to not less than 97.9 mils of tenth-normal silver nitrate V.S." *U. S.*

"White crystalline masses, or colorless fragments of six-sided rhombic prisms. Taste cool, saline. Soluble in 4 parts of *water*. Yields the *reactions* characteristic of potassium and of nitrates. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, calcium, magnesium, sodium, ammonium, chlorides, iodides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

It is devoid of water of crystallization, but is apt to contain a portion of liquid mechanically lodged within the substance of the crystals. This is particularly the case with the large crystals, and, according to Berzelius, is a source of impurity, as the liquid in question is a portion of the mother water in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be stirred during crystallization, so as to cause it to shoot into small crystals. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of nitre found in commerce under the name of *crystal mineral* or *sal prunelle*. If the heat is increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of nitrite, which, in powder, emits orange-colored fumes of hyponitric acid, and nitrous oxide on the addition of sulphuric acid. Upon a further continuance of the heat, the nitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. On account of the large proportion of oxygen which it affords, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coal, it deflagrates with bright scintillations. In the reaction of nitre with charcoal, carbon dioxide is produced, and never carbon monoxide, and the nitric acid is variously decomposed into nitrous oxide, nitrogen dioxide, or nitrogen, according to the proportion of the charcoal and to the heat employed. (A. Vogel, Jr.)

Potassium nitrate may be very readily recognized by its effect in increasing the combustion of live coals when thrown upon them, and by evolving white or reddish vapors on the addition of sulphuric acid. If the residue in this case weighs less than the amount calculated for potassium sulphate, part of it is probably

sodium sulphate, and the nitre tested may be assumed to have contained sodium nitrate. The most usual impurity is sodium chloride, which is seldom entirely absent, and which injures it for the manufacture of gunpowder. The refined or purified saltpetre of commerce is sufficiently pure for medicinal use. Potassium nitrate is composed of one atom of potassium in combination with one nitric acid group, which latter is monobasic.

Uses.—Potassium nitrate, when in sufficient concentration, acts upon a raw surface or a mucous membrane as a violent irritant, and taken internally in concentrated form produces violent burning pain, vomiting, purging, and other evidences of gastro-enteritis, which may end in collapse and death. Inflammation and ulceration of the mucous membrane are commonly found at the autopsies.

Potassium nitrate was formerly used extensively, and still is to a lesser extent, as a diuretic in *dropsy* and chronic *nephritis;* it has, however, no advantage over the vegetable salts and is much more prone to unduly irritate the kidney.

At one time potassium nitrate was used in very large doses in acute *rheumatism*, but the practice has passed out of vogue. An ounce taken in a little water has produced death, while recovery has been known from a dilute solution of several ounces. According to Lauter Brunton potassium nitrate has the same effect on the vascular system as the nitrite except that it is slower in its action. He recommends its use in the early stages of *arterio-capillary fibrosis* and other conditions of high arterial tension.

As a local remedy the nitrate is similar in its action to potassium chlorate, but it is probably less efficient, and certainly has been largely replaced by the chlorate in the treatment of *stomatitis, angina,* and local inflammations. In *asthma,* nitrous fumigation is often useful, performed by inhaling the fumes from burning torch paper, prepared by dipping blotting paper in a saturated solution of nitre and afterwards drying it. Such paper was official in the U. S. P. 1890. (See *Charta Potassii Nitratis,* Part III.) Vohl has examined the vapor resulting from the burning paper thus impregnated, and found it to consist of carbon dioxide and oxide, cyanogen, ammonia, nitrogen, aqueous vapor, and potassium carbonate and nitrite, and he ascribes the beneficial results of its inhalation to the ammonia and potassium nitrite. It is habitually added to stramonium leaves in the preparation of so-called asthmatic powders, but it is used under these circumstances more for its oxidizing effect in encouraging the combustion than for its own therapeutic action.

In pharmacy, potassium nitrate was formerly employed to form crocus of antimony, to procure nitric acid, and sometimes in the preparation of spirit of nitrous ether. In the laboratory it is used to make black and white flux, as an oxidizing agent, and to yield oxygen at a red heat. It was formerly employed in the production of aqua fortis (common nitric acid) and in the manufacture of sulphuric acid, and is yet employed in the fabrication of gunpowder. The Br. Pharmacopœia 1885 used it in the purification of bismuth.

Dose, five to ten grains (0.32–0.65 Gm.).

POTASSII PERMANGANAS. U. S., Br.

POTASSIUM PERMANGANATE Pot. Permang.

(pŏ-tăs'sĭ-ī pĕr-măn'gą-năs)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of $KMnO_4$ (158.03). Preserve it in glass-stoppered bottles. Potassium Permanganate when in solution or in the dry condition must not be brought into contact with organic or other readily oxidizable substances." *U. S.*

"Potassium Permanganate may be obtained by the interaction of potassium chlorate, potassium hydroxide, and manganese dioxide. It contains not less than 99 per cent. of pure potassium permanganate, $KMnO_4$." *Br.*

Potassæ Permanganas; Kali Hypermanganicum Crystallisatum; Hypermanganas Potassicus, s. Kalicus; Permanganate of Potash; Permanganate de Potasse, *Fr. Cod.;* Kalium permanganicum, *P. G.;* Kaliumpermanganat, Chamäleon, Uebermangansaures Kali, *G.;* Permanganato di potassio, *It.;* Permanganato potasico, *Sp.*

The British Pharmacopœia 1885 furnished a detailed process for this salt. (See *U. S. D.,* 19th edition, page 1013.)

By the British process potassium chlorate yields oxygen to manganese dioxide, converting it into manganic acid, which unites with the potassium hydroxide to form the manganate, potassium chloride being formed at the same time; the reaction being

$$3MnO_2 + 6KOH + KClO_3 = 3K_2MnO_4 + KCl + 3H_2O$$

When this solution is boiled, the green potassium manganate which is sometimes called *chameleon mineral,* reacts with the water and yields potassium permanganate, according to the reaction

$$3K_2MnO_4 + 3H_2O = K_2Mn_2O_8 + H_2MnO_3 + 4KOH$$

the hydrated peroxide separating out. Hence, when exhausted by water, the solution requires the saturation of the free alkali with carbon dioxide, as stated in the process above. At best, the product is small and uncertain in amount. A cheaper commercial preparation, consisting of a mixture more or less pure of sodium manganate and permanganate, is manufactured on a large scale for disinfecting purposes. It is obtained by mixing the sodium hydroxide obtained from 1500 kilogrammes of soda ash with 350 kilogrammes of finely divided manganese dioxide in a flat vessel, and heating this mixture for forty-eight hours to dull redness. The product is then lixiviated with water, and the solution either boiled down to the requisite

degree of strength or evaporated to dryness. Potassium permanganate has also been made by the electrolysis of the manganate, the products being permanganate, potassium hydroxide, and hydrogen. A still more interesting result of electrolysis is the production of potassium permanganate by the electrolysis of potassium hydroxide, in which the negative electrode is of porous copper oxide and the positive electrode a piece of manganese or ferro-manganese held immersed by a loop of platinum wire. A process for the complete conversion of manganate into permanganate has been patented in Germany. The crude manganate obtained in the usual way by melting manganese dioxide and alkali under access of air, is exhausted with water and a current of *ozonized* air is passed into and through the alkaline solution. The conversion of the manganate into permanganate is complete and rapid, whereas when ordinary oxygen is thus introduced the formation is slow and incomplete. (*Ph. Ztg.*, 1901, 517.)

Properties.—It is officially described as in "slender, monoclinic prisms, of a dark purple color, almost opaque by transmitted light, and of a blue, metallic luster by reflected light; odorless, and having (in solution) a taste at first sweet, but afterwards disagreeable and astringent. Permanent in the air. One Gm. of Potassium Permanganate dissolves in 13.5 mils of water at 25° C. (77° F.); also in 3.5 mils of boiling water; it is decomposed by alcohol. When heated, the salt decrepitates, and at about 240° C. (464° F.) it decomposes, yielding oxygen, potassium manganate, and manganese dioxide. An aqueous solution of the salt is of a deep violet-red color when concentrated, and of a rose color when highly diluted. The color is discharged by hydrogen sulphide, ferrous sulphate, oxalic acid, alcohol, and many other substances, especially if the solution is first rendered acid by sulphuric acid.

"**Assay.**—Dissolve about 0.15 Gm. of Potassium Permanganate, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, in 25 mils of distilled water, mix the solution with 1 mil of sulphuric acid and 50 mils of tenth-normal oxalic acid V.S. and warm the mixture to about 80° C. (176° F.). The residual titration with tenth-normal potassium permanganate V.S. shows, in the dried salt, not less than 99 per cent. of $KMnO_4$.

"Each mil of tenth-normal oxalic acid V.S. used corresponds to 0.0031606 Gm. of $KMnO_4$. Each gramme of Potassium Permanganate, previously dried, corresponds to not less than 313.2 mils of tenth-normal oxalic acid V.S." *U. S.*

"Dark purple, slender, prismatic, iridescent crystals. Taste sweet, astringent. Soluble in 20 parts of *water*. Aqueous solution neutral to *litmus*. The crystals heated to redness decrepitate, evolve oxygen, and leave a black residue from which *water* extracts potassium hydroxide, the resulting solution yielding the *reactions* characteristic of potassium. Yields no characteristic *reactions* for lead, arsenic, iron, sodium, ammonium, chlorides, nitrates, or sulphates. 1 gramme dissolved in *water*, acidified with 5 millilitres of *diluted sulphuric acid*, and heated to about 60° C. (140° F.), requires for complete decolorisation not less than 31.3 millilitres of *N/1 solution of oxalic acid.*" *Br.*

If the solution be evaporated to dryness, the salt has the form of an intensely black powder. If suddenly heated, the crystals detonate, evolving oxygen, and leaving a black residue, which yields potassium hydroxide to water, recognized by its alkaline reaction, and by giving, when acidulated with hydrochloric acid, a yellow precipitate with platinic chloride.

Moderately heated, the crystals are partially volatilized, giving out violet vapors of a disagreeable metallic odor. The salt, in consequence of the facility with which it parts with oxygen, is one of the most powerful oxidizing agents known. It causes the combustion of certain inflammable bodies, imparts oxygen to almost all organic substances, and in chemistry is employed to bring various compounds to a higher degree of oxidation. The readiness with which it yields oxygen in the nascent state is sufficient to account for its oxidizing power. It may be kept indefinitely if pure, and carefully secured from contact with organic substances, or other decomposing agents. In reference to the metals, mercury is quickly oxidized at the expense of the salt, a mixture of mercurous oxide and manganese oxide being deposited as a brown powder, and potassium hydroxide remaining in solution. Zinc remains unchanged indefinitely in a solution of the permanganate, silver is little affected, and copper not at all, even at 100° C. (212° F.). (Giles, *J. P. C.*, Mai, 1868, p. 397.)

H. B. Condy introduced (*J. Soc. Chem. Ind.*, 1885, p. 567) a permanganate disinfectant, which is commonly called *Condy's Fluid*, which contains also aluminum sulphate, which is said to increase the oxidizing effect of the permanganic acid. He asserts that in this disinfectant solution all the available oxygen of the permanganic acid is utilized, whereas only 60 per cent. of this amount is utilized with the simple alkaline permanganate.

Uses.—Potassium permanganate was brought to the notice of the profession by Condy in 1857, who recommended it as a powerful disinfectant. The findings of bacteriologists concerning the germicidal powers of this substance have varied most extraordinarily. These discrepancies have been due not solely to variations in the susceptibility of different species of bacteria but probably in greater degree, as pointed out by Sternberg, to the difference in conditions of test. In the absence of organic matter it is distinctly superior in power to phenol but it is so readily decomposed that in the presence of any considerable amount of pus or other albuminous matters it is almost inert. It appears to be especially poisonous towards *staphylococcus pyogenes*, Sternberg having shown that one part

in 833 is sufficient to destroy these bacteria in the absence of organic matter. Because of its activity as an oxidizant it is useful as a cleanser of *wounds* and the more so because of its deodorizing properties. One great disadvantage is its strong staining powers of the skin, clothes, etc. The stain may be removed with oxalic acid in places where the use of this substance is permissible. It is used in the treatment of *fetid* and *gangrenous ulcers, hospital gangrene, abscesses, carbuncles,* and *wounds* of all kinds, of fetid discharges from the mucous membrane, as in *ozena, otorrhea, gonorrhea,* and *leucorrhea,* and of *diphtheritic affections;* and it has proved serviceable even in *cancerous ulcers.* As a local stimulant it has also been used in *chronic* and *indolent ulcers.* In all these cases it is applied to the diseased surface in solution of various strengths, according to the effect desired. In concentrated solution it is capable of acting as a caustic and therefore requires caution. With the view to its caustic action, it may be sprinkled on the diseased surface by means of a pepper-box, or applied in saturated solution.

As an external disinfectant it is generally employed in strengths of from 1 to 5 per cent., but for application to mucous surfaces its strength must be greatly reduced and may be employed in strengths of from 1 part in 2000 and upwards.

Probably through its oxidizing influence potassium permanganate destroys many poisons and is a useful chemical antidote in *morphine* and *strychnine poisoning,* but especially in *snake bite.* The use of potassium permanganate as an antidote to snake poison was first suggested by Fayrer in 1869 and confirmed by Lauter Brunton in 1878. Rogers, of the Indian Medical Service (*C. D.,* June 18, 1904, and *Indian Medical Gazette,* December, 1912, xlvii), recommends the use of potassium permanganate crystals and has devised a special lancet. The instrument consists of a small lancet about half an inch long with a hollow wooden handle, in which crystals of permanganate are contained. The way in which it is proposed to apply the permanganate is that any one bitten by a snake should at once tear a strip from a turban, shirt, or any other article of clothing, and tie it as quickly as possible above the bite. A cut should then be made with the lancet over the site of the bite so as to convert the puncture made by the snake's tooth into a small wound. Into this the crystals of permanganate, moistened with saliva if necessary, are to be rubbed. This method of treatment he found to be highly successful in experimental poisoning of lower animals, but Bannerman (*Indian Journal of Medical Research,* 1913) concludes that a dog bitten by a cobra cannot be saved by the local application of powdered potassium permanganate rubbed in after free incision of the bitten place; nor by a similar application of a solution of the powder. It may be saved, however, by the immediate subcutaneous injection of 10 mils of a 5 per cent. solution of potassium permanganate; but this solution is so strong that gangrene of all the tissues of the foot is produced. If this treatment be delayed for even two minutes, a fatal result cannot be averted.

It is evident that like any other chemical antidote potassium permanganate must come in direct contact with the poison and since it is immediately decomposed by the tissues of the body, contrary to the statements occasionally made, it is useless after the absorption of the drug.

It is also recommended as a local hemostatic. Voerner (*M. M. W.,* 1905) recommends a mixture of one part of infusorial earth and two parts of potassium permanganate made up into a paste with one-third their bulk of petrolatum. Internally it was at one time employed in various *infectious diseases,* but its use for this purpose has entirely ceased. It is occasionally administered in *atonic amenorrhea.*

In overdose potassium permanganate may give rise to serious poisoning. Rubin and Dorner (*D. A. K. M.,* 1910, xcviii, p. 267), report a fatal case in which an unknown quantity was taken with suicidal intent. The symptoms were violent vomiting, profuse salivation with brownish masses of mucus, rapid respiration, albuminuria, and death fifty hours later. At autopsy there was found a bronchial pneumonia and punctiform hemorrhages in the pericardium.

Dose, from one to two grains (0.065–0.13 Gm.).

POTASSII SULPHAS. Br.

POTASSIUM SULPHATE

(pŏ-tăs'sĭ-ī sŭl'phās)

"Potassium Sulphate may be obtained by the interaction of sulphuric acid and potassium chloride or certain other potassium salts. It contains not less than 99 per cent. of pure potassium sulphate, K_2SO_4." *Br.* "It contains, when dried to constant weight at 100° C. (212° F.), not less than 99 per cent. of K_2SO_4 (174.27)." *N. F.*

Potassæ Sulphas; Sulfas Potassicus, s. Kalicus, Tartarum Vitriolatum, Arcanum Duplicatum, Sal Duobus, Sal Polychrestum Glaseri; Sulphate of Potash, Vitriolated Tartar; Sulfate de Potasse, *Fr. Cod.;* Potasse vitriolée, *Fr.;* Kalium Sulfuricum, *P. G.;* Kaliumsulfat, Schwefelsaures Kali, *G.;* Solfato di Potassio, *It.;* Sulfato potasico, *Sp.*

Potassium sulphate was deleted from the U. S. P. IX, but was introduced into the N. F. IV.

Potassium sulphate is naturally present in sea water, in some mineral waters, and in some other naturally occurring sources.

Several chemical processes give rise to potassium sulphate as a secondary product. Thus, it is produced in the distillation of nitric acid from a mixture of potassium nitrate and sulphuric acid; in the decomposition of magnesium sulphate by potassium carbonate, in one of the processes for preparing magnesium carbonate; in the manufacture of sulphuric acid; in the manufacture of potassium dichromate; and in the decomposition of potassium tartrate by cal-

cium sulphate. When nitric acid is obtained by calcining a mixture of nitre and ferrous sulphate, the residue consists of ferric oxide and potassium sulphate, the latter of which, being alone soluble, is separated by means of water, and crystallized from its solution. The impure potassium sulphate with sulphur, forming the residue of the combustion of sulphur and nitre in making sulphuric acid, is employed in the manufacture of alum. The *kainite* of the Stassfurt salt beds is a native double potassium and magnesium sulphate, combined with magnesium chloride, and the *schœnite,* a double potassium and magnesium sulphate, with 6 molecules of water. To obtain potassium sulphate, the former mineral is exposed to the air; it deliquesces, and as soon as the soluble magnesium chloride has been run off, the remaining salt is partially decomposed by boiling water, so that on cooling the difficultly soluble sulphate separates out.

According to the directions of the former Br. Pharmacopœia, the acid sulphate which remains after the distillation of nitric acid is brought to the neutral state by saturation, in boiling solution, with slaked lime. The solution is then filtered, to separate the calcium sulphate, and potassium carbonate is added at the boiling temperature, to remove lime and calcium sulphate. It is again filtered, then either neutralized or rendered slightly acid with diluted sulphuric acid, and finally, having been evaporated to a pellicle, is set aside for twenty-four hours to crystallize. The manufacturer of tartaric acid who avails himself of calcium sulphate to decompose potassium tartrate forms potassium sulphate as a collateral product. For the manner in which the latter salt may be economically crystallized for use, see *A. J. P.,* xxiii, 343.

Properties.—As officially described, it is in "colorless, hard rhombic prisms terminated by six-sided pyramids. Taste saline, slightly bitter. Decrepitates strongly when heated. Soluble in 10 parts of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of sulphates. 1 gramme dissolved in water acidified with *hydrochloric acid* gives, with *solution of barium chloride,* a white precipitate, which, when washed and dried, weighs not less than 1.326 grammes. Yields no characteristic *reactions* for copper, iron, calcium, magnesium, sodium, ammonium, or nitrates, and not more than the slightest *reactions* for chlorides. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Aqueous solution neutral to *litmus* (absence of acid potassium sulphate)." *Br.*

This salt was introduced into the National Formulary IV. It is an ingredient in *Sal Carolinum Factitium* or *Artificial Carlsbad Salt,* and *Sal Carolinum Factitium Effervescens or Effervescent Artificial Carlsbad Salt.* It is described as follows: "Potassium Sulphate occurs as hard, colorless, translucent, six-sided, rhombic prisms terminated by pyramids, or as a white powder; permanent in the air. Odorless; taste saline, somewhat bitter. One gramme dissolves in 10 mils of water at 25° C. (77° F.), and in 4 mils of boiling water; insoluble in alcohol. When heated the crystals decrepitate. At a bright red heat the salt fuses, and at a white heat partial decomposition occurs. An aqueous solution of the salt (1 in 20) is neutral to litmus. A saturated aqueous solution of the salt yields a white, crystalline precipitate with an excess of sodium bitartrate T.S. An aqueous solution of the salt (1 in 20) yields with barium chloride T.S. a heavy white precipitate, insoluble in hydrochloric acid. An aqueous solution of Potassium Sulphate does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirement of the Test for arsenic. (See Part III, U. S. P. Test No. 1.)

"**Assay.**—Dissolve about 0.6 Gm. of Potassium Sulphate, previously dried to constant weight at 100° C. (212° F.), and accurately weighed, in 100 mils of distilled water, acidulate the solution with hydrochloric acid and heat it to boiling. Gradually add an excess of barium chloride T.S., and heat for thirty minutes on a water bath; collect the precipitate of barium sulphate on a filter and wash it with distilled water until silver nitrate T.S. fails to produce an opalescence in 2 mils of the filtrate, previously acidulated with nitric acid. Dry the precipitate, ignite and weigh the residue. It corresponds to not less than 99 per cent. of K_2SO_4. Each gramme of Potassium Sulphate corresponds to not less than 1.326 Gm. of $BaSO_4$." *N. F.*

It consists of two atoms of potassium combined with the dyad group, SO_4, characteristic of sulphuric acid.

The *plate-sulphate of potassa,* described by Penny, of Glasgow, is, when pure, the double potassium and sodium sulphate, having the formula $3K_2SO_4 + Na_2SO_4$. It is so called from the circumstance of being crystallized in hard thick cakes, or slabs, consisting of successive crops of crystals. It is a technical product from kelp, and may be formed by allowing successive quantities of concentrated kelp-lye to run into coolers, there to crystallize in successive layers, the mother liquor being drawn off by a siphon after the deposit of each layer. Potassium acid sulphate $KHSO_4$, when subjected to electrolysis, yields potassium persulphate $K_2S_2O_8$, which is a powerful oxidizing agent sometimes used in bleaching. For the mode of preparing and using *Sal Polychrestum, Potassii Sulphas cum Sulphure,* or *Sulphate of Potassa with Sulphur,* see U. S. D., 15th ed., p. 1187.

Uses.—Potassium sulphate is a mild purgative, operating usually without heat, pain, or other symptom of irritation. In small doses, of from twenty grains to half a drachm (1.3–2.0 Gm.), it operates as an aperient; in larger doses, of four or five drachms (15.5–20 Gm.), it acts slowly as a purge, but because of its irritant action is not to be recommended. On the continent of Europe it is frequently given as an aperient after delivery, and for the purpose of drying up the milk. Potassium sulphate is a

powerful irritant in excessive doses, and capable of producing fatal poisoning; an ounce and a half (46.5 Gm.) of it are said to have caused death. It is, like the nitrate and the chlorate, more dangerous when not given in sufficiently dilute solution. (See *Am. J. M. S.*, N. S., vii, 88.)

Dose, twenty grains to two drachms (1.3–7.7 Gm.).

Off. Prep.—Pilula Colocynthidis Composita, *Br.;* Pulvis Ipecacuanhæ Compositus, *Br.;* Sal Carolinum Factitium, *N. F.;* Sal Carolinum Factitium Effervescens, *N. F.*

POTASSII TARTRAS. Br.

POTASSIUM TARTRATE

(pŏ-tăs'sĭ-ī tär'trăs)

"Potassium Tartrate may be obtained by neutralising Acid Potassium Tartrate with potassium carbonate. It contains not less than 99 per cent. of pure potassium tartrate, $(K_2C_4H_4O_6)_2H_2O$." *Br.*

Potassæ Tartras; Tartras Potassicus, s. Kalicus; Tartarus Tartarisatus, Tartarus Solubilis; Tartrate of Potash; Soluble Tartar; Tartrate de Potasse neutre, *Fr. Cod.;* Tartre soluble, Sel végétal, *Fr.;* Kalium Tartaricum, *P. G.;* Kaliumtartrat, *G.;* Tartrato neutro di potassio, *It.;* Tartrato potasico neutro, *Sp.*

This salt was dropped at the 1890 revision of the U. S. Pharmacopœia; it is retained in the 1914 revision of the British authority.

In the U. S. 1870 process the excess of acid in the bitartrate is saturated by the potassium of the carbonate, the carbon dioxide is liberated with effervescence, and the neutral potassium tartrate is formed. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring, and the addition continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the acid tartrate, since, from its variable quality, it is impossible to adjust precisely the proportions applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline, and hence, if inadvertently too much bitartrate has been used, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered, in order to separate calcium tartrate, which appears in white flocks, and which is frequently present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to insure a slow refrigeration, and after remaining at rest for several days the crystals begin to form. In order that the crystallization should proceed favorably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in the process, as that metal is apt to discolor the salt.

Potassium tartrate is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of calcium carbonate. This generates an insoluble calcium tartrate, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties.—Potassium tartrate is officially described in the Br. Ph. 1914 as in "small, colorless, four or six-sided prisms. Taste saline, cooling. Soluble in 1 part of *water.* Yields the *reactions* characteristic of potassium and of tartrates. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 16.8 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, or iron, and not more than the slightest *reactions* for calcium, magnesium, sodium, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 2 parts per million. Aqueous solution neutral to *litmus* (absence of acid potassium tartrate)." *Br.*

Potassium tartrate is composed of two atoms of potassium combined with the dyad group $C_4H_4O_6$ characteristic of tartaric acid.

Uses.—Potassium tartrate is a mild, cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to *febrile diseases,* and is occasionally combined with senna, the griping effects of which it has a tendency to obviate.

Dose, from a drachm to an ounce (3.9–31 Gm.).

POTASSIUM

POTASSIUM

(pŏ-tăs'sĭ-ŭm)

Potassium, *Fr.;* Kalium, Kalimetall, *G.;* Potassio, *It.;* Potasico, *Sp.*

Potassium is a metal forming the radical of potassium hydroxide, and of a number of compounds used in medicine. It was discovered in 1807 by H. Davy, who obtained it by decomposing fused potassium hydroxide by a voltaic current. It was afterwards procured in larger quantity by Gay-Lussac and Thénard, by bringing the fused alkali in contact with white-hot iron, which attracted the oxygen and set free the metal. The process of Brunner, as modified by Wöhler, consists in decomposing potassium carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible. For an account of some improvements in Brunner's process by Mareska and Donny, see *A. J. P.,* xxv, 70. Castner has also prepared it by the process invented by him for the manufacture of metallic sodium. It may also be prepared by distilling a mixture of potassium fluoride or fluosilicate with metallic aluminum. (For commercial sources of potassium salts, see under *Potassii Carbonas.*)

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white color. A newly-cut surface is brilliant, but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from almost every other substance. On account of this property it must be kept in liquids, such as naphtha, which are devoid of oxygen. On the same account, when exposed with a freshly cut surface to the air, it becomes luminous through a slow combustion, like phosphorus, in the dark. (*Chem. News*, Feb. 28, 1868, p. 108.) Its sp. gr. is 0.865, melting point 62.5° C. (144.5° F.), atomic weight 38.86, and symbol K. It volatilizes at about 720° C. (1328° F.) with the production of greenish vapors. When thrown upon water it floats, takes fire, and burns with a rose-colored flame, combining with oxygen, and generating potassium hydroxide which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic elements, and with several of the metals. It combines in three proportions with oxygen, forming a suboxide (K_4O) and a monoxide (K_2O) of a gray color, and a tetroxide (K_2O_4) of a yellowish-brown color. It also unites with chlorine, and forms official compounds with iodine, bromine, cyanogen, and ferrocyanogen, under the names of potassium iodide, bromide, cyanide, and ferrocyanide. Its monoxide is a strong salifiable base existing in nature always in combination, and forming with acids a numerous and important class of salts.

Uses.—Although elemental potassium is not used in medicine it enters into so large a number of medicinal salts and so greatly modifies the action of some of them, that the effects of the potassium ion deserve a separate word of consideration. While the presence of a certain amount of potassium in the blood is essential for vital activity, a very slight increase in its percentage has a deleterious influence on many organs. The injection of a potassium salt into the circulation weakens the contractile power of all muscle fiber but affects especially the heart and blood vessels. It also exercises a marked depressant action upon the central nervous system, including the spinal cord, brain, and medulla. Although the depressant action of potassium is strong when it is injected directly into the blood stream, when taken by the mouth it exercises very little influence upon the circulation. This is due to the fact that it is excreted by the kidneys so rapidly that it cannot be absorbed in sufficient amounts through the alimentary tract to cause the accumulation of a poisonous dose in the blood. When the kidneys, however, are diseased it is probable that a poisonous dose of the ion could be absorbed from the intestines, and therefore while the potassium salts can be used with great liberality in healthy persons when there are diseases of the kidneys some caution is necessary in their employment. During the passage of the potassium through the system it appears to exercise a marked effect upon the metabolism. Not only is there an increase in the total solid matters of the urine, but apparently a disproportionate increase in the quantity of urea. This has led to the opinion that the increased elimination is not simply the result of its diuretic action, but betokens a more complete oxidation in the system. Because of this effect the potassium salts are generally preferred in cases of deficient combustion, especially that group of disorders known as *lithemia*.

PRUNUS VIRGINIANA. U. S. (Br.)

WILD CHERRY **Prun. Virg.** **[Wild Black Cherry Bark]**

(prū′nŭs vĭr-ĝĭn-ị-ā′nạ)

"The stem-bark of *Prunus serotina* Ehrhart (*Prunus virginiana* Miller) (Fam. *Rosaceæ*), collected in autumn and carefully dried. Preserve Wild Cherry in tightly-closed containers, protected from light." *U. S.* "Wild Cherry Bark is the bark of Prunus serotina, *Ehrh.*, collected in autumn." *Br.*

Pruni Virginianæ Cortex, *Br.*, Wild Cherry Bark; Virginian Prune Bark; Rum, Whisky, or Cabinet Cherry, Wild Black Cherry; Ecorce de Cerisier de Virginie, *Fr.*; Wildkirschenrinde, Amerikanischer Zierstrauch, *G.*

The genus Prunus now includes the plums, almonds, peaches, apricots, and cherries, and comprises about one hundred and twenty species. They are generally distributed in the temperate regions of the northern hemisphere. In the United States there are about forty indigenous species.

The name *P. virginiana* was applied by Miller (*Dict.*, ed. 8, No. 3), and not Linnæus, to *P. serotina* Ehr. *P. virginiana* L., commonly called *wild cherry* or *choke cherry*, is distinguished from *P. serotina* Ehr., known more properly as *wild black cherry*, by the following characteristics: *P. virginiana* L. has deciduous calyx lobes; oblong-obovate pointed endocarp (or stone); leaves broadly oval to oblong-obovate, and usually abruptly acuminate; inner bark with a rather disagreeable odor. *P. serotina* Ehr. has persistent calyx lobes; the endocarp (or stone) oblong-obovate, usually gradually acuminate; leaves oblong or lanceolate-oblong, usually gradually acuminate; the inner bark and leaves possess an aromatic odor. The British name, "Virginian Prune Bark," for the bark is misleading; Virginian Peach Bark or Virginian Almond Bark would have been no more of a misnomer. The official species is, according to Michaux, one of the largest productions of the American forest. Trees were observed by that botanist on the banks of the Ohio, from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But as usually met with in the Atlantic States the tree is much smaller. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk

is regularly shaped, and covered with a rough blackish bark, which detaches itself semicircularly in thick narrow plates. The leaves are alternate, oval-oblong, or lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green; the petioles are furnished with one or more reddish conspicuous glands. The flowers are small, white, and occur in long erect or spreading racemes. They appear in May, and are followed by globular drupes, about the size of a pea, and when ripe of a shining blackish-purple color. For a paper on the structure of species of Prunus, by E. S. Bastin, see *Proc. A. Ph. A.*, 1895, 211.

This tree is distributed from Ontario south to Florida, and westward to Dakota, Nebraska, Kansas, Indian Territory, and Eastern Texas. It extends along the mountain ranges of Western Texas, Mexico, and Pacific regions of Central America, Colombia, and Peru. In the United States it was once common throughout the Appalachian region. In the neighborhood of Philadelphia it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint which deepens with age. The leaves have been found by Procter to yield volatile oil and hydrocyanic acid on distillation, and in such proportion that a water distilled from them might with propriety be substituted for the cherry-laurel water. (*Proc. A. Ph. A.*, 1858, 325.) The fruit has a sweetish, astringent, bitter taste, and is much used in some parts of the country to impart flavor to spirituous liquors. The bark is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. The revisers of the Pharmacopœia believe with J. S. Perot that the bark is stronger when collected in autumn than in the spring; from a portion gathered in April Perot obtained 0.0478 per cent. of hydrocyanic acid, and from another in October 0.1436 per cent., or about three times as much. (*A. J. P.*, xxiv, 111.) The bark should be preferred recently dried, as it deteriorates by keeping. A. B. Stevens (*Proc. A. Ph. A.*, 1895, 226; 1896, 215), after testing many specimens, reached the conclusion that bark procured from different parts of the same tree varied in the yield of hydrocyanic acid, the value being in this order: 1, root; 2, twigs; 3, trunk; the bark from young trees yielding more glucoside than that from old trees. Jos. L. Lemberger (*A. J. P.*, 1872, 303) believes that tannic acid is most abundant in the bark in October and November. On the other hand, Grace E. Cooley (*A. J. P.*, August, 1897) concludes that there is more tannic acid in the bark during the active growth of the spring than in the autumn. She further states that in the spring and autumn the bark contains its maximum percentage of starch; so that if the bark, whether powdered or whole, contains much starch in its parenchymatous cells, it has been collected after the time of leaf-fall in the autumn or before the unfolding of the leaves in the spring. Occasionally barks find their way into commerce as Prunus Virginiana which yield no odor of hydrocyanic acid when moistened and are probably obtained from other than the official wild cherry. (See Bastin, *A. J. P.*, 1895, and Finnemore, *P. J.*, 72.)

Moser points out that collectors frequently mistake *P. virginiana* L. or choke cherry for *P. serotina* Ehrh. or black cherry, which is the official source of wild cherry bark. He presents a description of the two trees and of the characteristic features of their barks. (*A. J. P.*, 1909, lxxxi, p. 579.) Farwell reports that the bark of *P. demissa* (Nutt.) Walpers, a tree from west of the Rocky Mountains, has been found in commerce. It is much darker and the lenticels are much more prominent. The preparations made from it resemble the official wild cherry bark in color, odor and taste.

Properties.—Wild cherry bark is officially described as follows: "Usually in transversely curved pieces from 2.5 to 8 cm. in length and from 0.5 to 4 mm. in thickness; outer surfaces light brown or greenish-brown, smooth, except for numerous lenticels from 3 to 4 mm. in length; inner surfaces light brown, longitudinally striate and occasionally fissured; fracture short, granular; odor distinct, bitter almond-like when macerated in water; taste astringent, aromatic, and agreeably bitter. Under the microscope, sections of Wild Cherry show a tendency for the separation in radial segments or bands of the phloem tissues from the rather broad medullary rays; periderm usually of a few layers of cells; outer bark from young twigs with 1 or 2 nearly continuous layers of cells, the latter being of very irregular shape, often branching and with thick lamellated, porous walls; medullary rays extending in more or less scythe-shaped groups from the cambium to the outer bark, from 1 to 10 cells in width, some of the cells occasionally being modified to stone cells; between the medullary rays occur numerous small groups of stone cells, resembling those of the outer bark and occasionally modified to sclerenchymatous fibers; calcium oxalate mostly in crystal fibers consisting of monoclinic prisms, from 0.015 to 0.04 mm. in diameter, also in rosette aggregates from 0.01 to 0.04 mm. in diameter; starch grains numerous, occurring in the medullary rays and parenchyma. The powder is light brown; when examined under the microscope it exhibits bast-fibers and stone cells with thick, strongly lignified walls; crystal fibers with monoclinic prisms and rosette aggregates of calcium oxalate, from 0.01 to 0.04 mm. in diameter; starch grains nearly spherical, from 0.003 to 0.004 mm. in diameter." *U. S.*

"In curved pieces or irregular fragments not more than three millimetres thick. Frequently covered with a smooth, thin, reddish-brown, papery cork, or, if this has been removed, exhibiting a greenish-brown cortex; marked with transversely elongated lenticels. Fracture short, granular; fractured surface reddish-grey. Inner surface reddish-brown, striated or reticulately

fissured. In the bark numerous groups of sclerenchymatous cells of characteristic shape, but no typical bast fibers; in the parenchymatous cells minute starch grains and prismatic crystals of calcium oxalate. Slight odor; taste astringent, aromatic and bitter, recalling that of bitter almonds." *Br.*

In the fresh state, or when treated with water, it emits an odor resembling that of peach leaves. Its taste is agreeably bitter and aromatic, with the peculiar flavor of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Madeira wine in appearance. Its peculiar flavor and its medicinal virtues are injured by boiling, in consequence partly of the volatilization of the principles upon which they depend, partly upon a chemical change effected by the heat. From an analysis by Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, lignin, red coloring matter, salts of calcium, potassium, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water successively from several different portions of the bark. William Procter proved that, as in the case of bitter almonds, the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of water with amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, he affirmed that the agency of another principle, probably analogous to, if not identical with, *emulsin* or the *synaptase* of Robiquet, was also essential, and, as this principle becomes inoperative at the boiling temperature, one can understand how decoction may interfere with the virtues of the bark. (*A. J. P.*, x, 197.) The bitterness appears to be due to the fluorescent substance described below which confirms Procter, who found the bitterness of an extract of the bark to remain after it had been wholly deprived of amygdalin. Stevens and Judy (*A. J. P.*, 1895, 482, 534) found that the thick bark contains more amygdalin and consequently yields more HCN than the thin bark. The thick bark contains amygdalin, etc., 4.12 per cent., and HCN from 0.32 to 0.35 per cent.; the thin bark, amygdalin, etc., 3.16 per cent., and HCN from 0.24 to 0.27 per cent. F. B. Power and Henry Weimer, on the other hand, state that the bark does not contain crystallizable amygdalin, that the ferment principle is not emulsin, and that it cannot be isolated by an analogous process. The bitter principle, which appears to be the fluorescent substance, has the character of a glucoside, and crystallizes in colorless needles. (*West. Drug.*, 1887, p. 331.)

R. Rother (*A. J. P.*, 1887, p. 286), in searching for the fluorescent principle of wild cherry bark, obtained a reddish crystalline substance, soluble in water, chloroform, ether, and alcohol, the solution of which fluoresced strongly on addition of ammonia. Rother says that it does not agree in crystalline form with mandelic acid, but may be a derivative of it.

Uses.—Wild cherry bark has the stomachic effects of the simple bitters but is comparatively infrequently employed for this purpose. On the theory that hydrocyanic acid is a cough sedative, wild cherry bark has been popularly employed in the treatment of *bronchitis* of various types, but is of doubtful service.

Dose, from thirty to sixty grains (2.0–3.9 Gm.).

PULVERES

POWDERS

(pŭl'vẹ-rēs)

Poudres, *Fr.;* Pulvern, *G.;* Polveri, *It.;* Polvos, *Sp.*

The form of *powder* is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure.

With regard to keeping powders in well-stoppered bottles, it is asserted by Hérouard, a French pharmacist, that this plan, instead of preserving *some* powders, tends to their more speedy and certain change. Whatever pains may be taken in drying drugs previously to powdering them, most of them during the process attract moisture, so as to put themselves in this respect in equilibrium with the surrounding air; and, if enclosed in this state in air-tight vessels, they are exposed to injurious influence from their own absorbed water, which, vaporized in hot weather, is in the colder seasons condensed on the inner surface of the vessel and determines a movement of fermentation, and even cryptogamic growths appear in some instances. The best method of preservation, the author thinks, is to enclose the powders in strong paper bags of a blue or gray color, so as to exclude the light, while the air has exit or entrance through the porous walls. Whatever may be our theoretical opinions on the point, Hérouard asserts the fact, as the result of observation, that powders keep best in this way, and his statement coincides with our own experience. The powders may be more likely to cake or harden into aggregate masses; but this disadvantage is easily counteracted by a new pulverization when required. (*J. P. C.*, Août, 1862, p. 98.) From these statements the inference may be drawn that, where powders are kept in air-tight bottles, they should be thoroughly dried, after pulveriza-

tion, before being enclosed, and many, such as ergot, rhubarb, etc., should be kept in paper boxes or cartons.

In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.

Powders may be divided into the *simple,* consisting of a single substance, and the *compound,* of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept,—the former because they render the preparation damp and liable to spoil, the latter because they are apt to become rancid and impart an unpleasant odor and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in waxed paper or other impervious covering; and the same remark is applicable to volatile powders, as ammonium carbonate and camphor. The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar. For many powders the *cachet de pain* affords the best method of administration.

These very useful articles are wafers made of unleavened bread in such a manner that they offer a concavity, so that when two are placed face to face there is a space in which a powder may be contained. They are of different sizes and capacities, the largest readily holding as much as ten grains of quinine. In filling them, one wafer is placed upon a board, and the requisite amount of medicine is put in it; then a second wafer, whose interior margin has been wetted, is laid upon the first and pressed down upon it. When taken, they should be dipped in water, placed immediately upon a teaspoon containing a little water, and swallowed with a gulp of fluid. For most powders of disagreeable taste, cachets afford the best method of administration.

Gelatin capsules are extensively used for the administration of drugs in powdered form and are admirably adapted for this purpose if the dose is not too large, as they are readily filled and easily taken by the patient.

In the act of powdering, the whole substance in the mortar should not be beaten until completely pulverized, as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated, so that there is a loss of time and of material. The proper plan is to sift off the fine powder after a short continuance of the process, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and shifting, until the process is completed. Care should be taken to mix thoroughly the several portions of fine powder thus obtained.

PULVIS AMYGDALÆ COMPOSITUS. Br.

COMPOUND POWDER OF ALMONDS

(pŭl'vĭs ą-mŷg'dą-læ cŏm-pŏş'ĭ-tŭs)

Confectio Amygdalæ; Conserva Amygdalarum; Confection of Almond; Conserve d'Amandes, *Fr.;* Mandelconserve, *G.*

"Sweet Almonds, 60 *grammes;* Refined Sugar, in powder, 30 *grammes;* Gum Acacia, in powder, 10 *grammes.* Blanch and dry the Almonds; reduce them to a coarse powder; mix the Gum Acacia and Sugar; add to the powdered Almonds; mix." *Br.*

This is the old *Almond Confection* in powder form. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds, requires much time, and which cannot be kept ready made. But from its liability to be injured by keeping, it was omitted from the U. S. Pharm., which directs the emulsion of almond to be made immediately from the ingredients.

Off. Prep.—Mistura Amygdalæ, *Br.*

PULVIS ANTIMONIALIS. Br.

ANTIMONIAL POWDER [James's Powder]

(pŭl'vĭs ăn-tĭ-mō-nĭ-ā'lĭs)

Pulvis Antimonii Compositus, Pulvis Jacobi; Poudre antimoniale de James, *Fr.;* Jamessches Antimonpulver, *G.*

"Antimonious Oxide, 25 *grammes;* Calcium Phosphate, 50 *grammes.* Mix." *Br.*

This preparation was introduced into the U. S. Pharmacopœia, 1890, as a substitute for the different forms of antimonial powder formerly official with the British Colleges, because of its revived employment at that time, but was not admitted to the U. S. P. VIII or IX, but is included in the N. F. IV (see Part III). The N. F. and the British preparations are identical.

The only essential difference between the official and the Dublin powder is that the ingredients of the former are taken already prepared and mixed in fixed proportion, while those of the latter result simultaneously from one operation. The official powder is, of course, much more easily prepared, and less liable to uncertainty from any error in the process.

Michael Donovan believes that none of the official formulas fairly represent James's powder, and gives an elaborate history of this celebrated proprietary medicine, and a method for its preparation, in *P. J.,* 1869.

Uses.—This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. Until within a few years it was often prescribed in febrile diseases, with a view to its diaphoretic effect. According to A. T. Thomson, it is advantageously given in *acute rheumatism,* con-

joined with camphor, calomel, and opium, and with calomel and guaiac in several *cutaneous affections.* The estimation in which this preparation is held varies greatly; but it is generally admitted that, as formerly prepared, it was very uncertain in the percentage of antimony trioxide, and consequently in its activity; it was this uncertainty that led to its omission from the U. S. Pharm. of 1830.

The antimonial powder at present official is exempt from the objection of irregularity of composition. Nevertheless, as it depends for its greater or less energy on the presence or absence in the alimentary canal of an acid which may form a salt with the antimonial oxide, it cannot always be relied on for a definite effect, being sometimes mild, and sometimes more active than might be desirable.

Dose, as a diaphoretic, from three to eight grains (0.2–0.5 Gm.) every third or fourth hour, given in the form of pill. In larger doses it is purgative and emetic. Jonathan Osborne has found the trioxide, given separately in three grain (0.2 Gm.) doses, evening and night, to cause in some cases nausea and vomiting, in others mild purgation.

PULVIS AROMATICUS. U. S. (Br.)

AROMATIC POWDER Pulv. Arom.

(pŭl'vĭs ăr-o-măt'ĭ-cŭs)

Pulvis Cinnamomi Compositus, *Br.;* Compound Powder of Cinnamon; Poudre des Épices, P. des Aromates, Poudre aromatique, *Fr.;* Aromatisches Pulver, Gewürzpulver, *G.*

* "Saigon Cinnamon, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Jamaica Ginger, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Cardamom Seed (deprived of pericarps), *fifteen grammes* [or 231 grains]; Myristica, freshly grated, *fifteen grammes* [or 231 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the cardamom seed and the myristica with a portion of the saigon cinnamon, until they are reduced to a fine powder; then add the remainder of the cinnamon and the ginger, and rub them together until they are thoroughly mixed." *U. S.*

"Cinnamon Bark, in powder, 25 *grammes;* Cardamom Seeds, in powder, 25 *grammes;* Ginger, in powder, 25 *grammes.* Mix." *Br.*

Properties.—"Light reddish-brown; with a strong, distinctive, aromatic odor; when examined under the microscope it exhibits characteristic starch grains of ginger, being ellipsoidal or ovoid, slightly beaked and from 0.005 to 0.06 mm. in diameter; numerous yellowish-brown, brownish-red and occasional blackish fragments, the cellular structure of which is not distinct; occasional stone cells, the lumina being filled usually with a reddish-brown amorphous substance or containing air; occasional fragments with sclerenchymatous fibers; calcium oxalate crystals, in short raphides, few." *U. S.*

The Aromatic Powder of the U. S. P. IX does not differ essentially from that formerly official. The British and American powders now closely resemble each other. The U. S. process contains nutmeg and the British does not. The cardamom seeds should always be deprived of their pericarps before being weighed, and the powder, when prepared, should be kept in well-stoppered bottles.

Uses.—The aromatic powder is stimulant and carminative, and the U. S. preparation may be given in the dose of from ten to thirty grains (0.65–2.0 Gm.), in cases of *enfeebled digestion with flatulence;* but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such a mixture is commonly called *spice plaster* and will be found in the N. F. IV (Part III), under the title *Pulvis Aromaticus Rubefaciens.* It contains clove, cinnamon, ginger, and capsicum, and the mixed powder may be distributed in a thin flannel bag, quilted in position, and the whole wet with bathing whisky when applied and covered with oiled silk.

Aromatic Sugar.—Wm. L. Turner proposed a mode of obtaining the effects of the aromatic powder in certain cases where the use of the powder itself would be inconvenient. He prepared an aromatic sugar by submitting eight ounces of the freshly prepared powder to percolation with stronger alcohol to exhaustion, pouring the percolate over eight ounces of sugar, and evaporating at a low heat. The sugar thus prepared may be added to mixtures, solutions, etc., requiring aromatic addition. (*A. J. P.,* 1869, p. 118.)

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Fluidextractum Aromaticum, *U.S.*

PULVIS BUTEÆ SEMINUM. Br.

POWDER OF BUTEA SEEDS

(pŭl'vĭs bū-tē'æ sĕm'ĭ-nŭm)

"Soak Butea Seeds in Distilled Water; carefully remove the integuments; dry and powder the kernels." *Br.*

Uses.—(See *Butea Semina.*)

PULVIS CATECHU COMPOSITUS. Br.

COMPOUND POWDER OF CATECHU

(pŭl'vĭs kăt'ę-çhū cŏm-pŏs'ĭ-tŭs)

Pulvis Gambir Compositus, *N.F.;* Poudre de Cashcuttie composée, *Fr.;* Zusammengesetztes Katechupulver, *G.*

"Catechu, in powder, 40 *grammes;* Kino, in powder, 20 *grammes;* Krameria Root, in powder, 20 *grammes;* Cinnamon Bark, in powder, 10 *grammes;* Nutmeg, in powder, 10 *grammes.* Mix." *Br.*

This preparation is also official in the N. F. (see Part III).

The *dose* of this agreeable preparation is from fifteen to thirty grains (1–2 Gm.).

PULVIS CRETÆ AROMATICUS. Br.

AROMATIC POWDER OF CHALK

(pŭl'vĭs crē'tæ ăr-ǫ-măt'ĭ-cŭs)

Confectio Aromatica, *Lond.;* Poudre de Craie aromatique, *Fr.;* Gewürztes Kreidepulver, *G.*

"Cinnamon Bark, in powder, 10 *grammes;* Nutmeg, in powder, 8 *grammes;* Cloves, in powder, 4 *grammes;* Cardamom Seeds, in powder, 3 *grammes;* Refined Sugar, in powder, 50 *grammes;* Prepared Chalk, 25 *grammes.* Mix." *Br.*

This is the former "Aromatic Powder" of the Br. Pharmacopœia, with the addition of chalk and elision of saffron. It is also official in the N. F. IV (see Part III). It is a warm stimulant and astringent, as well as antacid, and is well calculated for *diarrhea* connected with acidity and without inflammation. In such a combination, however, the due proportion and even the choice of the ingredients vary so much with the symptoms that they might well be left to extemporaneous prescription.

Dose, from thirty to sixty grains (2.0–3.9 Gm.), in mucilage or sweetened water, frequently repeated.

Off. Prep.—Pulvis Cretæ Aromaticus cum Opio, *Br.* (*N. F.*).

PULVIS CRETÆ AROMATICUS CUM OPIO. Br.

AROMATIC POWDER OF CHALK WITH OPIUM

(pŭl'vĭs crē'tæ ăr-ǫ-măt'ĭ-cŭs cŭm ō'pĭ-ō)

Pulvis Cretæ et Opii Aromaticus, *N. F.;* Aromatic Powder of Chalk and Opium; Poudre de Craie Opaciée, *Fr.;* Kreidepulver mit Opium, *G.*

"Aromatic Powder of Chalk, 97.5 *grammes;* Opium, in powder, 2.5 grammes. Mix. This Powder contains 2.5 per cent. of Opium." *Br.*

The N. F. powder is identical with the Br. (see Part III).

The addition of the opium greatly increases the efficacy of the compound powder of chalk in *diarrhea,* and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Forty grains of the powder contain a grain of opium.

Dose, for adults, ten to twenty grains (0.65–1.3 Gm.).

PULVIS CRETÆ COMPOSITUS. U. S.

COMPOUND CHALK POWDER Pulv. Cret. Co.

(pŭl'vĭs crē'tæ cǫm-pŏs'ĭ-tŭs)

Poudre de Craie composée, *Fr.;* Kreidepulver mit Gummi, *G.*

* "Prepared Chalk, *thirty grammes* [or 1 ounce av., 25 grains]; Acacia, in fine powder, *twenty grammes* [or 309 grains]; Sugar, in fine powder, *fifty grammes* [or 1 ounce av., 334 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the powders intimately by trituration and pass the product through a No. 60 sieve." *U. S.*

This official powder was introduced into the U. S. P., 1890, for the purpose of having on hand, in a convenient form, the dry powders necessary to make chalk mixture. (See *Mistura Cretæ.*)

This powder will be found, however, a very convenient basis for administering chalk in powder, and it will be easy to direct the addition of morphine, kino, pepsin, bismuth subnitrate, or any other suitable agent.

Dose, one-half to two drachms (2.0–7.7 Gm.).

Off. Prep.—Mistura Cretæ, *U. S.*

PULVIS EFFERVESCENS COMPOSITUS. U. S. (Br.)

COMPOUND EFFERVESCING POWDER Pulv. Eff. Co. [Seidlitz Powder]

(pŭl'vĭs ĕf-fẹr-vĕs'cẹns cǫm-pŏs'ĭ-tŭs)

"The weight of the mixture in a blue paper is not less than 9.5 Gm. nor more than 10.5 Gm.; it contains not less than 23 per cent. nor more than 27 per cent. of sodium bicarbonate and not less than 73 per cent. nor more than 78 per cent. of potassium and sodium tartrate." *U. S.*

Pulvis Sodæ Tartaratæ Effervescens, *Br.,* Effervescent Tartarated Soda Powder; Pulveres Effervescentes Aperientes, *U. S.* 1870; Seidlitz Powders; Poudre Gazogène laxative, *Fr. Cod.;* Poudre gazifère purgative, Poudre de Seidlitz, *Fr.;* Pulvis aërophorus laxans, *P. G.;* Pulvis aërophorus Seidlitzensis, Abführendes Brausepulver, Seidlitzpulver, *G.;* Polvo gasifero laxante, *Sp.*

* "Sodium Bicarbonate, dried and in fine powder, *thirty grammes* [or 1 ounce av., 25 grains]; Potassium and Sodium Tartrate, dried and in fine powder, *ninety grammes* [or 3 ounces av., 76 grains]; Tartaric Acid, dried and in fine powder, *twenty-six grammes* [or 401 grains]. Mix the sodium bicarbonate intimately with the potassium and sodium tartrate, divide the mixture into *twelve equal parts,* and wrap each part in a separate blue paper. Then divide the tartaric acid into *twelve equal parts,* and wrap each part in a separate white paper. Keep the powders in well-closed containers, in a dry place.

"To five mils of an aqueous solution of the mixture in a blue paper (1 in 20) add 5 mils of acetic acid, and when effervescence has ceased, shake the solution vigorously; a white crystalline precipitate, soluble in ammonia water, separates." *U. S.*

"No. 1 Sodium Potassium Tartrate, in dry powder, 7.5 *grammes;* Sodium Bicarbonate, in dry powder, 2.5 *grammes.* Mix. No. 2 Tartaric Acid, in dry powder, 2.5 *grammes.* Put No. 1 in blue paper, and put No. 2 in white paper." *Br.*

"**Assay for Sodium Bicarbonate.**—Mix thoroughly the contents of a blue paper, then dissolve 2 Gm. of it in 80 mils of distilled water, add 20 mils of half-normal sulphuric acid V.S., boil the solution until the volume is reduced to about 50 mils, and titrate the excess of acid with half-normal potassium hydroxide V.S., phenolphthalein T.S. being used as indicator.

The number of mils of half-normal sulphuric acid V.S. consumed shows not less than 23 per cent. nor more than 27 per cent. of sodium bicarbonate.

"Each mil of half-normal sulphuric acid V.S. corresponds to 0.04200 Gm. of sodium bicarbonate. Each gramme of the mixture corresponds to not less than 5.48 mils nor more than 6.43 mils of half-normal sulphuric acid V.S.

"Assay for Potassium and Sodium Tartrate.—Proceed as directed under the assay for alkali salts of organic acids (see Part III, Test No. 6), using 2 Gm. of the mixture taken from the blue paper used in the preceding assay. The difference between the number of mils of half-normal sulphuric acid V.S. consumed in this assay and in the assay for sodium bicarbonate, multiplied by 0.07055, represents the potassium and sodium tartrate, and corresponds to not less than 73 per cent. nor more than 78 per cent.

"The sum of the percentages of sodium bicarbonate and of the potassium and sodium tartrate is not less than 99 per cent." *U. S.*

Though named from the saline springs of Seidlitz, in Bohemia, Seidlitz powders do not correspond in composition with those famous waters. Of each pair of powders, one, much the smaller of the two, contains about thirty-five grains (2.25 Gm.) of tartaric acid, the other about forty grains (2.59 Gm.) of sodium bicarbonate mixed with about two drachms (7.7 Gm.) of Rochelle salt. The acid powder is usually put into a white paper, the alkaline into a blue paper, which latter should not be colored by aniline; a number of them are enclosed in a paper or tin box. They should not be kept in a damp place, as the tartaric acid is liable to be dissolved by the moisture and absorbed into the substance of the paper, thus altering the due proportion of the ingredients. We have known the whole of the contents of the white paper thus to disappear in the course of two or three years. The Rochelle salt is the ingredient upon which the aperient property mainly depends. In their administration, each powder is dissolved separately, the smaller in a fluidounce or more of water, the larger in twice or three times the quantity, and the two solutions are mixed gradually. A reaction takes place between the tartaric acid and the sodium bicarbonate, by which sodium tartrate is produced, adding somewhat to the laxative property of the draught, and carbon dioxide escapes, causing a brisk effervescence. The acid is in slight excess, and thus causes an agreeable acidity in the solution.

Uses.—These powders are refrigerant and aperient, and generally very acceptable to the stomach in consequence of the carbon dioxide eliminated. They are especially adapted to *febrile cases* with a somewhat irritable stomach. One pair of them will generally operate slightly, but, if required, two may be given at once, or the dose may be repeated every three or four hours until the desired effect is produced. The flavor may sometimes be advantageously improved by adding syrup of ginger, orange peel, or lemon to one of the solutions before admixture, and most persons prefer to dissolve the salts in very cold water, the saline taste being thereby greatly diminished. A lowering of the temperature always takes place, due to the solution of the salts.

Dose, one set of two powders.

PULVIS GLYCYRRHIZÆ COMPOSITUS. U. S., Br.

COMPOUND POWDER OF GLYCYRRHIZA Pulv. Glycyrrh. Co. [Compound Licorice Powder]

(pŭl'vĭs glĭç-ŷr-rhĭ'zæ cŏm-pŏs'ĭ-tŭs)

Poudre de Réglisse composée, Poudre pectorale, *Fr.;* Pulvis Liquiritiæ Compositus, *P. G.;* Brustpulver, Pulvis Pectoralis Kurellæ, *G.*

* "Senna, in No. 80 powder, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Glycyrrhiza, in No. 80 powder, *two hundred and thirty-six grammes* [or 8 ounces av., 142 grains]; Washed Sulphur, *eighty grammes* [or 2 ounces av., 360 grains]; Oil of Fennel, *four grammes* [or 62 grains]; Sugar, in fine powder, *five hundred grammes* [or 17 ounces av., 279 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the oil of fennel thoroughly with about one-half of the sugar, then add the remainder of the sugar and the other ingredients, and mix thoroughly. Finally, pass the powder through a No. 80 sieve, pulverize the residue if any should be left on the sieve, add to the sifted powder, and mix thoroughly. Keep it in well-closed containers." *U. S.*

"Senna Leaves, in powder, 16 *grammes;* Liquorice Root, in powder, 16 *grammes;* Fennel Fruit, in powder, 8 *grammes;* Sublimed Sulphur, 8 *grammes;* Refined Sugar, in powder, 52 *grammes.* Mix." *Br.*

Properties.—"Greenish-yellow to greenish-brown with a fennel-like odor; when mounted in water or hydrated chloral T.S. and examined under the microscope, Compound Powder of Glycyrrhiza shows fragments of glycyrrhiza with their characteristic yellow fibers associated with crystal fibers, large tracheæ with elliptical, bordered pores and cells containing numerous, spherical starch grains varying from 0.002 to 0.02 mm. in diameter; also fragments of senna as shown by their characteristic, more or less bent, unicellular, non-glandular hairs, from 0.1 to 0.35 mm. in length, fragments of epidermis with elliptical stomata and their 2 neighboring cells and fragments with crystal fibers; upon the addition of potassium hydroxide T.S. to aqueous mounts of the powder, some of the fragments are immediately colored a yellowish-red, changing to a reddish-brown. Introduce 0.1 Gm. of Compound Powder of Glycyrrhiza into a test tube, moisten it with 2 mils of alcohol, then add 10 mils of water, boil the mixture, allow it to cool and then filter; the filtrate is of a pale yellowish-brown color, which changes immediately to a yellowish-red on the addition of a drop of potassium hydroxide T.S. Compound Powder of Glycyrrhiza is free from an odor of hydrogen sulphide." *U. S.*

This official preparation, which was introduced

into the U. S. P., 1880, was identical with that of the German Pharmacopœia, and in the 1885 revision of the British Pharmacopœia the preparation was made nearly to correspond, being slightly deficient in senna. The U. S. P., 1890, replaced the powdered fennel with oil of fennel, increasing the proportion of powdered licorice correspondingly which is an improvement, as powdered fennel is variable in quality; great care should be used, however, to employ only fresh oil of fennel. The object of the oil of fennel is patent, but the advantage to be gained by the use of washed sulphur in the proportion of only 8 per cent. must be purely imaginary. In our opinion, an improvement would be the substitution of two grammes each of powdered cinnamon and cloves for four grammes of the sugar, to correct the griping effect which is frequently produced.

Dose, thirty to sixty grains (2.0–3.9 Gm.), used as an agreeable laxative.

PULVIS IPECACUANHÆ ET OPII. U. S. (Br.)

POWDER OF IPECAC AND OPIUM Pulv. Ipecac. et Opii [Compound Powder of Ipecac, Dover's Powder, Opii et Ipecacuanhæ pulvis compositus P. I.]

(pŭl'vĭs ĭp-ẹ-căc-ŭ-ăn'hæ ĕt ō'pĭ-ī)

Pulvis Ipecacuanhæ Compositus, *Br., U. S.* 1870; Compound Powder of Ipecacuanha; Poudre d'Ipécacuanha Opiacée, *Fr. Cod.;* Poudre de Dover, *Fr.;* Pulvis Ipecacuanhæ Opiatus, *P. G.;* Doversches Pulver, *G.;* Polvere di oppio e di ipecacuana, Polvere del Dower, *It.;* Polvo de ipecacuana opiado, Polvo de Dower, *Sp.*

* "Ipecac, in No. 60 powder, *ten grammes* [or 154 grains]; Powdered Opium, *ten grammes* [or 154 grains]; Sugar of Milk, in No. 30 powder, *eighty grammes* [or 2 ounces av., 360 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate these together thoroughly until the mixture is reduced to a very fine, uniform powder." *U. S.*

"Ipecacuanha Root, in powder, 10 *grammes;* Opium, in powder, 10 *grammes;* Potassium Sulphate, in powder, 80 *grammes.* Mix. This Powder contains 10 per cent. of Opium." *Br.*

Properties.—"Grayish-white or very light brown; under the microscope it exhibits coarse, angular, frequently more or less cone-shaped, colorless fragments from 0.03 to 0.4 mm. in length, very slowly soluble in water and hydrated chloral T.S. and strongly polarizing light with a strong display of colors (fragments of *sugar of milk*); numerous starch grains of ipecac, their presence confirmed by the addition of iodine T.S., and varying from 0.003 to 0.017 mm. in diameter; occasional fragments of tracheids of ipecac; and occasional fragments with the more or less tabular, characteristic stone cells of the capsules of the opium poppy, with their light brown, porous and strongly lignified walls." *U. S.*

The substitution of powdered sugar of milk for potassium sulphate in crystals as formerly used cannot be said to have improved this well-known powder, except in making it more agreeable to the taste. The U. S. process should have directed the powder to be sifted, in order to secure a thorough blending of the ingredients; the sifting should on no account be omitted by the operator. The potassium sulphate or the crystalline sugar of milk serves to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha upon which the peculiar virtues of the compound depend, the potassium sulphate being preferable on account of the greater hardness of its particles. They also serve to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though called Dover's Powder, does not precisely correspond with that originally recommended by Dover, which was prepared as follows: Four ounces of potassium nitrate and the same quantity of potassium sulphate were mixed in a red hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecac and an ounce of licorice root, in powder, were mixed with the other ingredients. This process was adopted in a former French Codex, and has been retained with little change in the present. For a method of valuing Dover's Powder, by A. B. Prescott, see *A. J. P.,* Dec., 1878.

Uses.—This combination is widely employed under the name of Dover's Powder as a diaphoretic and sedative. It is especially prized in the early stages of the milder infections, such as *colds* and *influenza,* in which an effort is to be made to abort the disease by sweating. Because of its combination of sudorific and analgesic action it is also frequently employed in *muscular rheumatism.* Ordinarily as a sudorific about five grains should be administered either stirred up in water or as a bolus and preferably in connection with hot drinks and other measures for encouraging sweating. The dose may be repeated in four to six hours, when it is desirable to maintain a continued sudorific action.

Dose, three to ten grains (0.2–0.65 Gm.).

Off. Prep.—Pilula Ipecacuanhæ cum Scilla, *Br.*

PULVIS JALAPÆ COMPOSITUS. U. S., Br.

COMPOUND POWDER OF JALAP Pulv. Jalap. Co. [Pulvis Purgans]

(pŭl'vĭs jạ-lā'pæ cọm-pŏs'ĭ-tŭs)

Pulvis Purgans, Pulvis Jalapæ Tartratus, Pulvis Cathartic us; Poudre de Jalap composée, *Fr.;* Jalapenpulver mit Weinstein, *G.*

* "Jalap, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Potassium Bitartrate, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the powders intimately by trituration and pass the product through a No. 60 sieve." *U. S.*

"Jalap, in powder, 30 *grammes;* Acid Potassium Tartrate, in powder, 60 *grammes;* Ginger, in powder, 10 *grammes.* Mix." *Br.*

Properties.—"Very light brown; when examined under a microscope it exhibits numerous, sharp-angular, colorless fragments mostly somewhat rectangular and with straight edges varying from 0.03 to 0.3 mm. in length, slowly soluble in water or hydrated chloral T.S. and polarizing light with a strong display of colors (fragments of crystals of *potassium bitartrate*); numerous starch grains of jalap, readily distinguished without the use of iodine T.S., usually single, occasionally 2- to 3-compound, and varying from 0.003 to 0.035 mm. in diameter; occasional fragments of laticiferous vessels and parenchyma with yellowish-brown walls, or tracheæ with bordered pores, and rosette aggregates of calcium oxalate from 0.01 to 0.035 mm. in diameter, that occur in jalap." *U. S.*

The rubbing of the bitartrate with the jalap is thought to favor its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), forms a good cathartic in *dropsy*.

Dose, of the powder, from thirty grains to a drachm (2.0–3.9 Gm.).

PULVIS KALADANÆ COMPOSITUS. Br.

COMPOUND POWDER OF KALADANA

(pŭl'vĭs kă-lă-dā'næ cŏm-pŏs'ĭ-tŭs)

"Kaladana, in powder, 30 *grammes;* Acid Potassium Tartrate, in powder, 60 *grammes;* Ginger in powder, 10 *grammes.* Mix." *Br.*

This powder is used as a cathartic.

Dose, from ten to sixty grains (0.65–3.9 Gm.).

PULVIS KINO COMPOSITUS. Br.

COMPOUND POWDER OF KINO

(pŭl'vĭs kī'nō cŏm-pŏs'ĭ-tŭs)

Pulvis Kino et Opii Compositus, *N. F.*, Compound Powder of Kino and Opium; Pulvis Kino cum Opio, *Br.* 1864; Powder of Kino and Opium; Poudre de Kino Opiacée, *Fr.;* Kinopulver mit Opium, *G.*

"Kino, in powder, 75 *grammes;* Opium, in powder, 5 *grammes;* Cinnamon Bark, in powder, 20 *grammes.* Mix. This Powder contains 5 per cent. of Opium." *Br.*

The N. F. powder is practically identical with the Br. (see Part III).

This is an anodyne astringent powder, useful in some forms of *diarrhea*, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances. Twenty grains contain one grain of opium.

Dose, from five to twenty grains (0.32–1.3 Gm.).

PULVIS OPII COMPOSITUS. Br.

COMPOUND POWDER OF OPIUM

(pŭl'vĭs ō'pī-ī cŏm-pŏs'ĭ-tŭs)

Poudre d'Opium composée, *Fr.;* Zusammengesetztes Opiumpulver, *G.*

"Opium, in powder, 10 *grammes;* Black pepper of commerce, in powder, 15 *grammes;* Ginger, in powder, 30 *grammes;* Caraway Fruit, in powder, 42 *grammes;* Tragacanth, in powder, 3 grammes. Mix. This Powder contains 10 per cent. of Opium." *Br.*

This seems to have been introduced in order to have at hand all the dry ingredients of the Confection of Opium. (See *Confectio Opii.*) Ten grains (0.65 Gm.) of the powder contain one grain (0.065 Gm.) of opium.

PULVIS RHEI COMPOSITUS. U. S., Br.

COMPOUND POWDER OF RHUBARB Pulv. Rhei Co.

(pŭl'vĭs rhē'ī cŏm-pŏs'ĭ-tŭs)

Magnesia and Rhubarb, Gregory's Powder; Poudre de Rhubarbe composée, *Fr.;* Pulvis Magnesiæ cum Rheo, *P. G.;* Kinderpulver, Pulvis Infantum, *s. P. Antacidus, G.*

* "Rhubarb, in No. 60 powder, *twenty-five grammes* [or 386 grains]; Magnesium Oxide, *sixty-five grammes* [or 2 ounces av., 128 grains]; Jamaica Ginger, in No. 60 powder, *ten grammes* [or 154 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the rhubarb and ginger together, then gradually add the magnesium oxide and continue the trituration until they are thoroughly mixed, then pass through a No. 60 sieve." *U. S.*

"Rhubarb Root, in powder, 22 *grammes;* Light Magnesia, 66 *grammes;* Ginger, in powder, 12 *grammes.* Mix." *Br.*

Properties.—"A pinkish-white, mobile powder, becoming darker on exposure to moisture; when examined under the microscope it exhibits fine particles of magnesium oxide, numerous starch grains and characteristic fragments of vegetable tissues; starch grains of ginger, more or less elliptical or ovoid, frequently with a prominent beak, from 0.005 to 0.06 mm. in diameter; starch grains of rhubarb, single or compound, either spherical or polygonal, often with a central cleft, from 0.002 to 0.02 mm. in diameter; mounts made with hydrated chloral T.S. give a strong effervescence and show more clearly the fragments of reticulate tracheæ, the reddish-brown parenchyma of rhubarb with numerous small starch grains or rosette aggregates of calcium oxalate, varying from 0.05 to 0.1 mm. in diameter. With solutions of the alkalies many of the fragments of rhubarb become of a deep red color." *U. S.*

This is a good laxative antacid, well adapted to *bowel complaints*, especially in children.

Dose, for an adult, from one-half to one drachm (2.0–3.9 Gm.); for a child two or three years old, from five to ten grains (0.32–0.65 Gm.).

PULVIS SCAMMONIÆ COMPOSITUS. Br.

COMPOUND POWDER OF SCAMMONY

(pŭl'vĭs scam-mō'nĭ-æ cŏm-pŏs'ĭ-tŭs)

"Scammony Resin, in powder, 50 *grammes;* Jalap, in powder, 35 *grammes;* Ginger, in powder, 15 *grammes.* Mix." *Br.*

This does not appear to us a very eligible preparation.

Dose, from ten to twenty grains (0.65–1.3 Gm.).

PULVIS TRAGACANTHÆ COMPOSITUS. Br.

COMPOUND POWDER OF TRAGACANTH

(pŭl'vĭs trăg-ą-căn'thæ cŏm-pŏs'ĭ-tŭs)

"Tragacanth, in powder, 15 *grammes;* Gum Acacia, in powder, 20 *grammes;* Starch, in powder, 20 *grammes;* Refined Sugar, in powder, 45 *grammes.* Mix." *Br.*

This is applicable to the general purposes of the demulcents, but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders.

Dose, one-half to one drachm (2.0–3.9 Gm.).

PYRETHRUM. U. S. (Br.)

PYRETHRUM Pyreth. [Pellitory Root]

(pȳ-rē'thrŭm)

"The dried root of *Anacyclus Pyrethrum* (Linné) De Candolle (Fam. *Compositæ*). Preserve Pyrethrum in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.* "Pyrethrum Root is the dried root of Anacyclus Pyrethrum *DC.*" *Br.*

Pyrethri Radix, *Br.;* Pyrethrum Root; Radix Pyrethri Romani; Spanish Chamomile, Longwort, Pellitory of Spain; Pyrèthre officinal, *Fr. Cod.;* P. vrai, Salivaire, *Fr.;* Bertramwurzel, Römische Bertramwurzel, *G.;* Pelitre (Raiz de), *Sp.*

Anacyclus Pyrethrum is perennial, and sends up numerous stems, usually trailing at the base, erect in the upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow, nearly linear segments of a pale-green color. The florets of the disk are yellow; the rays white on their surface, and reddish or purple beneath and at their edges.

The plant is a native of Northern Africa, the Levant, and the Mediterranean coast of Europe, being also cultivated. The root is the part used under the name of pellitory, or *pellitory of Spain.*

The German Pharmacopœia formerly recognized the root of *Anacyclus officinalis* Hayne (*A. Pyrethrum* Schrader), a plant cultivated in Magdeburg. The roots are smaller and thinner, attaining a length of 25 cm. and a thickness of 5 cm. They are externally grayish-brown; the bark is not radiating and does not contain many stone cells, such as are present in the official pyrethrum. The taste resembles that of the official drug but is even more pungent.

Properties.—Pyrethrum is officially described as "nearly cylindrical, slightly tapering, usually in pieces from 2.5 to 10 cm. in length and from 5 to 20 mm. in diameter; externally dark brown, deeply longitudinally furrowed and somewhat wrinkled, occasionally bearing short, tough, hair-like rootlets, crown more or less annulate, and occasionally tufted with coarse fibers or with long, soft-woolly, nearly straight, 1-celled hairs; fracture short; bark dark brown with 1 or 2 circular rows of resin ducts, closely adhering to the light yellow, radiate, porous wood, in the medullary rays of which occur 1 to 3 rows of resin ducts; odor distinct; taste sweetish, pungent, very acrid, tingling and producing a strong sialogogue effect. The powder is light to dark brown; when examined under the microscope it exhibits numerous spherical or irregular masses of inulin, the nature of which is especially seen with polarized light, and lignified fragments of the woody tissues and stone cells associated with cork; inulin in spherical granules or irregular masses, from 0.01 to 0.1 mm. in diameter, which is not affected by the addition of iodine T.S.; tracheæ with simple pores and reticulate or scalariform thickenings, usually associated with wood parenchyma and with few or no wood fibers; stone cells in groups, the cells more or less tabular in outline and with thick, yellowish porous walls; cork in yellowish-brown or dark brown fragments. Pyrethrum yields not more than 5 per cent. of ash." *U. S.*

"Usually from five to ten centimetres long, and from ten to fifteen millimetres thick; unbranched, nearly cylindrical, or frequently tapering towards both extremities; the crown often bearing a tuft of nearly colorless hairs. Outer surface brown and longitudinally wrinkled. Fracture short. In transverse section, numerous, narrow, yellowish wood-bundles alternating with wider, brownish-grey medullary rays; in the cortex and medullary rays scattered, yellowish-brown oleo-resin ducts; in the parenchymatous tissue inulin, but no starch. Characteristic odor; taste pungent, salivant." *Br.*

Its analysis by Koene gives, in 100 parts, 0.59 of a brown, very acrid substance, of a resinous appearance, and insoluble in potassium hydroxide (this is stated to contain *pelletonin*), 1.06 of a dark brown, very acrid, fixed oil, soluble in potassium hydroxide; 0.35 of a yellow acrid oil, also soluble in potassium hydroxide; traces of tannin; 940 parts of gum; inulin; 7.60 parts of potassium sulphate and carbonate, potassium chloride, calcium phosphate and carbonate, alumina, silica, etc., and 19.80 of lignin, besides loss. (See A. J. P., viii, 175.) Buchheim (*A. E. P. P.,* v, 458) claims to have discovered as the active principle an alkaloid, *pyrethrine,* which, treated with alcoholic potassium hydroxide, splits up like piperine, and yields *pyrethric acid.* Schneegans (*Proc. A. Ph. A.,* 1897, 736) has obtained this pyrethrine in long branched needles united in tufts, melting at 46° C. (114.8° F.), with an extremely burning taste. It is soluble in absolute alcohol, acetone, ether, strong acetic acid, chloroform, and carbon disulphide, yields a yellow solution, which soon changes to red.

A *false pellitory root* has been identified by E. M. Holmes as the product of *Corrigiola telephiifolia.* It is readily distinguished from the true root by its being softer and more flexible, by its having a distinctly sweetish taste, and especially by the transverse section of the root, which is of a yellowish-white color, with from three to five pale opaque concentric rings, each alternating with a narrower translucent horny ring.

Uses.—Pellitory is a powerful irritant, used

almost exclusively as a sialagogue in certain forms of *headache, rheumatic* and *neuralgic affections* of the face, *toothache,* etc., or as a local stimulant, in *palsy of the tongue or throat,* and in relaxation of the uvula. For these purposes it may be chewed, or employed as a gargle in decoction of vinous tincture. The dose as a masticatory is from thirty grains to a drachm (2.0–3.9 Gm.). Its action upon the general system has not been studied to any extent, but 50 minims of a tincture of it very nearly killed a child three and a half years old. The symptoms were those of gastro-enteritis, followed by convulsions. (*London Practitioner,* Aug., 1876.) An alcoholic extract is sometimes employed by dentists as a local anesthetic application to *carious teeth.*

Dose, twenty grains (1.3 Gm.).

Off. Prep.—Tinctura Pyrethri, *U. S., Br.*

PYROGALLOL. U. S.

PYROGALLOL Pyrogall. [Pyrogallic Acid]

(pȳ-rō-găl'lŏl)

"Trihydroxybenzene [$C_6H_3(OH)_3$ 1 : 2 : 3 = 126.05]. Preserve it in well-closed containers, protected from light." *U. S.*

Acidum Pyrogallicum; Trihydroxybenzene; Pyrogallol, *Fr. Cod.;* Acide Pyrogallique, *Fr.;* Pyrogallolum, *P. G.;* Pyrogallol, Pyrogallussäure, *G.;* Pirogallol, *It.*

Of the three triatomic phenols indicated by theory, this is the best known, *phloroglucin* and *oxyhydroquinone* being the other two. It may be prepared synthetically, but is usually obtained as one of the results of the decomposition of gallic acid by heat, and may be obtained by submitting extract of galls to sublimation, the reaction produced by the heat being:

$$C_7H_6O_5 = C_6H_6O_3 + CO_2$$

The vapors of pyrogallol rise, and condense on the upper surface of the paper diaphragm. The chief difficulty in the process is to properly regulate the heat, as at a high temperature this acid passes rapidly into *metagallic acid,* and thus the product is diminished. According to Löwig, it is best prepared by heating gallic acid, previously dried at 100° C. (212° F.), in a glass retort, by means of a zinc chloride bath, to 210° C. (410° F.), when the pure pyrogallol sublimes. It is stated by De Luynes and Espandieu that in the ordinary method of obtaining pyrogallic acid much of the acid is lost. According to Pelouze, the proportion of pyrogallic acid produced ought to be very nearly 75 per cent., but the processes in use yield only 25 per cent., the pyrogallic acid itself undergoing rapid decomposition at an elevated temperature. De Luynes and Espandieu have succeeded in preventing this loss by decomposing gallic acid in water under pressure, instead of by dry sublimation. Gallic acid is introduced into a bronze boiler with twice or three times its weight of water; the temperature is raised to a point ranging from 200° C. (392° F.) to 210° C. (410° F.), and maintained at that point for half an hour, when the liquid is allowed to cool. The boiler now contains a slightly colored solution of pyrogallic acid. This is heated with a little pure animal charcoal, filtered, evaporated sufficiently, and set aside to crystallize. The crystalline mass obtained is somewhat colored. To obtain it entirely white, nothing more is necessary than to distil it in a vacuum. The product is quite 75 per cent. The carbon dioxide escapes through the joinings of the apparatus, while the aqueous vapor is retained. (*A. J. P.,* 1866, p. 22.) Another equally satisfactory procedure is that of Thorpe, for details of which see *A. J. P.,* 1881, p. 53, 236.

Properties.—It is officially described as in "light, white, or nearly white laminæ or fine needles; odorless, and having a bitter taste. It acquires a grayish tint on exposure to air and light. One Gm. of Pyrogallol dissolves in 1.7 mils of water, 1.3 mils of alcohol, and in 1.6 mils of ether at 25° C. (77° F.); very soluble in boiling water or boiling alcohol. It melts between 129° and 133° C. (264.2° and 271.4° F.). An aqueous solution of Pyrogallol (1 in 10) reduces solutions of the salts of silver, gold, and mercury even in the cold. When freshly prepared, 1 mil of an aqueous solution of Pyrogallol (1 in 20) is colored brownish-red by a few drops of ferric chloride T.S. A blue color is produced in an aqueous solution of Pyrogallol (1 in 20) by freshly prepared ferrous sulphate T.S. Incinerate about 1 Gm. of Pyrogallol; not more than 0.1 per cent. of ash remains. A freshly prepared solution of Pyrogallol (1 in 20), in recently boiled distilled water, is colorless or at most slightly yellow, and is neutral or only slightly acid to litmus. The solution gradually acquires a brown color on exposure to the air and an acid reaction due to the absorption of oxygen; the absorption of oxygen and change of color take place very rapidly if the solution contains an alkali hydroxide." *U. S.*

According to Rosing, of Christiana, it is always partially converted, when sublimed, into metagallic acid, to which probably it owes its acid reaction as generally found in commerce; for when quite pure it has no influence on litmus paper. It is a triatomic phenol, $C_6H_3(OH)_3$, and is therefore, properly speaking, not an acid at all; hence the change in the official title to "Pyrogallol." One of its characteristic properties is its strong affinity for oxygen, in consequence of which it instantly undergoes change by contact with chlorine, iodine, bromine, and the acids which readily yield oxygen. Through the same property it rapidly reduces some of the metallic oxides, and its use in photography as a developing agent is based on this effect exercised on the salts of silver. Though unalterable in the air when quite dry, it is rapidly changed in alkaline solution by the absorption of oxygen, so that it may be used for ascertaining the proportion of this gas in a mixture of gases. By the action of phthalic anhydride upon pyrogallol is formed *gallein,* a dye color much used in calico printing. By the action of glacial acetic acid upon pyrogallol in the presence of

zinc chloride is formed *gallacetophenone*, $CH_3—CO—C_6H_2(OH)_3$, which has been used in medicine as a substitute for pyrogallol.

Uses.—Pyrogallol is an active irritant and in concentrated solution even caustic. It is somewhat germicidal, though distinctly inferior to phenol in power; according to Cooper (*B. M. J.*, 1912, i, 1235), its phenol coefficient is 0.8. When taken internally it is actively poisonous, its toxic effect being due in part to its local irritant action upon the alimentary tract, but also partly from a phenol-like action upon the central nervous system and a destructive effect upon the blood corpuscles. It causes a solution of the hemoglobin from the latter and a change of hemoglobin into methemoglobin, which, if death does not occur too soon, is manifested by the appearance of icterus and methemoglobinuria.

The toxic symptoms produced by it are vomiting and purging with collapse, pale or cyanosed lips, the skin often presenting a peculiar greenish hue or sometimes jaundiced; the urine is albuminous and may be brown or black from the presence of hemoglobin or methemoglobin. Fatty degenerations and enlargement of the liver, similar to those produced by phosphorus, have been noted by Personne. (*C. R. A. S.*, Oct., 1869.)

Even its external use is not devoid of danger, two deaths having been reported from its topical application, and Kuseh (*W. K. W.*, 1909) reports abortion in pregnant women from a 10 per cent. ointment.

Pyrogallol is used in medicine solely as an application in various skin diseases, especially *psoriasis*. In this condition it owes its therapeutic action probably to its reducing powers, although its local stimulating effect and antibacterial properties may also play a part in its usefulness. It is occasionally used in *lupus* for its caustic action. For medical purposes it is generally applied in the form of an ointment varying in strengths of from two to ten per cent.

PYROXYLINUM. U. S., Br.

PYROXYLIN Pyroxylin. [Soluble Gun Cotton]

(py-rŏx-y-lĭ'nŭm)

"A product obtained by the action of a mixture of nitric and sulphuric acids on cotton and consisting chiefly of cellulose tetranitrate [$C_{12}H_{16}(ONO_2)_4O_6 = 504.17$]. Preserve it in cartons, packed loosely, and protected from light and moisture." *U. S.*

Pyroxylon, *U. S.* 1870; Colloxylin, Gun Cotton, Collodion Cotton; Fulmicoton soluble. *Fr.*; Kollodiumwolle, *G.*; Piroxilina, *Sp.*

The process of the U. S. P., 1890, for making *pyroxylin* was not introduced into the U. S. P. VIII or IX. It is as follows: "Purified Cotton, *one hundred grammes* [or 3 ounces av., 231 grains]; Nitric Acid, *fourteen hundred cubic centimeters* [or 47 fluidounces, 163 minims]; Sulphuric Acid, *twenty-two hundred cubic centimeters* [or 74 fluidounces, 187 minims]; Alcohol, Ether, Water, each *a sufficient quantity*. Mix the Acids gradually in a glass or porcelain vessel, and, when the temperature of the mixture has fallen to 32° C. (89.6° F.), add the Purified Cotton. By means of a glass rod imbue it thoroughly with the Acids, and allow it to macerate, until a sample of it, taken out, thoroughly washed with a large quantity of Water, and subsequently with Alcohol, and pressed, is found to be soluble in a mixture of *one volume* of Alcohol and *three volumes* of Ether. Then remove the Cotton from the Acids, transfer it to a larger vessel, and wash it, first, with cold Water, until the washings cease to have an acid taste, and then with boiling Water, until they cease to redden blue litmus paper. Finally, drain the Pyroxylin on filtering paper, and dry it in small, detached pellets, by means of a water-bath or steam-bath, at a temperature not exceeding 60° C. (140° F.). Keep the Pyroxylin, loosely packed, in well-closed vessels containing not more than about 25 Gm., in a cool and dry place, remote from lights or fire."

"Cotton, 10 *grammes;* Sulphuric Acid, 50 *millilitres;* Nitric Acid, 50 *millilitres;* Distilled Water, *a sufficient quantity*. Mix the Acids in a porcelain mortar; immerse the Cotton in the mixture, and after it is thoroughly wetted by the Acids stir it for three minutes with a glass rod; transfer it to Distilled Water, wash until free from acid, drain, and dry the Pyroxylin in a warm room." *Br.*

Gun cotton was discovered by Schönbein, of Basel, in Switzerland. The name is applied to several closely related yet distinct products. They are not, as was at first supposed, nitro-derivatives in which the group NO_2 merely replaces hydrogen, atom for atom, but compounds in which the nitric acid residue NO_3 is present, replacing OH groups of the cellulose formula. Thus, taking the doubled formula $C_{12}H_{20}O_{10}$ for cellulose, there is produced by the action of nitric acid under different circumstances $C_{12}H_{14}O_4(NO_3)_6$, and following this, successively, $C_{12}H_{15}O_5(NO_3)_5$, $C_{12}H_{16}O_6(NO_3)_4$, $C_{12}H_{17}O_7(NO_3)_3$, and $C_{12}H_{18}O_8(NO_3)_2$. The first of these, the hexanitrate, is insoluble in alcohol and ether, and constitutes the true explosive gun cotton. The soluble gun cotton used in the preparation of *collodium* is a varying mixture of the four lower nitrates, but is chiefly made up of the tri- and tetra-nitrates. (Tollens, *Handbuch der Kohlenhydrate,* 1888.) The hexanitrate, when very thoroughly washed free from acid, is insoluble in water, alcohol, ether, and all mixtures of alcohol with ether. It constitutes the true explosive gun cotton, which when compressed in cakes and fired by a fulminate explodes with great violence. Other compounds intermediate between some of these have been described by different chemists, but Abel, the chemist of the Woolwich Arsenal in England, has shown that they were imperfectly purified preparations.

Properties.—Gun cotton has the appearance of ordinary cotton, but is harsh to the touch. When intended for solution it is best made by

the joint action of sulphuric and nitric acids, or, as proposed by Ellet of the South Carolina College, of potassium nitrate and sulphuric acid. Experience has thoroughly shown that the use of the acids as practised in the 1890 official formula gives better results than the employment of potassium nitrate and sulphuric acid, which was directed in the U. S. P. 1860. For Flint's process and that of E. Senft, for pyroxylin, see U. S. D., 19th edition, pages 1030 and 1031.

Care should be exercised not to let the mixture attain a temperature much above 32° C. (89.6° F.). It is insoluble in water, and nearly so in alcohol, but dissolves freely in acetic ether and amyl acetate. (*A. J. P.*, 1887, 275.) The following are the official description and tests: "Pyroxylin is a yellowish-white, matted mass of filaments, resembling raw cotton in appearance, harsh to the touch; exceedingly inflammable, burning, when unconfined, very rapidly and with a luminous flame; less explosive than cellulose hexanitrate. When kept in well-closed bottles and exposed to the light, it is decomposed with the evolution of nitrous vapors, leaving a carbonaceous residue. It is slowly but completely soluble in 25 parts of a mixture of 3 volumes of ether and 1 volume of alcohol. Soluble in acetone and in glacial acetic acid and precipitated from these solutions on the addition of water. Saturate 0.5 Gm. of Pyroxylin with alcohol in a dish placed in cold water and then ignite the Pyroxylin at the top. When combustion is completed and the dish heated to redness, not more than 0.3 per cent. of ash remains. Stir 1 Gm. of Pyroxylin with 20 mils of distilled water; the latter does not acquire an acid reaction, and on evaporating 10 mils of the filtered liquid to dryness on a water bath, not more than 0.0015 Gm. of residue remains (*soluble impurities*)." *U. S.*

"Resembles cotton-wool, but is somewhat harsher to the touch. Highly inflammable. Readily soluble in a mixture of equal volumes of *alcohol* (90 per cent.) and *ether* (distinction from gun-cotton)." *Br.*

Guichard proposes the use of chemically pure filtering paper as yielding a superior product to cotton. He takes 1400 parts of sulphuric acid, sp. gr. 1.82; 700 parts of nitric acid, sp. gr. 1.37; 70 parts of the paper; puts the mixed acid in a vessel surrounded by cold water to keep down the temperature, drops the paper in leaf by leaf, allows it to stand three hours, and then washes freely with water. (*J. P. C.*, 4e sér., xii, 290.) When kept for long periods, gun cotton is liable to spontaneous decomposition. The change is shown by the bottle in which the gun cotton is kept becoming full of nitrous acid vapor, and the substance is so far altered that it is no longer explosive or soluble in ether. Bouet states that the decomposition from exposure to light takes place sooner in gun cotton which has been prepared with potassium nitrate and sulphuric acid than where the mixed acids have been used. He says that, with both, the sides and bottom of the bottle are nearly covered with crystals of oxalic acid. (See *A. J. P.*, March, 1862, p. 187.) The official direction to keep pyroxylin "in cartons, protected from the light" is a valuable precaution against decomposition. When kindled, gun cotton flashes off like gunpowder, burning without residue. Yet, according to Bleekrode, when wet with ether, or similar fluid, and touched with a light, the liquid will burn out of it without firing it. (*J. P. C.*, 4e sér., xviii.) Its inflaming point is at 187.7° C. (370° F.). Marx makes it lower. Prepared in various forms after acting upon it with solvents like amyl acetate, etc., to convert it into a plastic mass, the higher nitrates constitute the well known "smokeless powders" now so largely used in warfare. Pyroxylin, or soluble gun cotton, is now extensively used as the basis of transparent varnishes for lacquering metal and wood. The solvent employed is usually a mixture of methyl alcohol or acetone with petroleum benzin, the miscibility of which is affected by the addition of small quantities of compound ethers like amyl acetate. In medicine it is used as a protective covering, especially in the form of collodion.

Off. Prep.—Collodium, *U. S.*, *Br.*

QUASSIA. U. S. (Br.)

QUASSIA Quass. [Bitter Wood]

(quâs'sĭ-ą)

"The wood of *Picrasma excelsa* (Swartz) Planchon, known in commerce as Jamaica Quassia, or of *Quassia amara* Linné, known in commerce as Surinam Quassia (Fam. *Simarubaceæ*)." *U. S.* "Quassia Wood is the wood of the trunk and branches of Picræna excelsa, *Lindl.*" *Br.*

Quassiæ Lignum, *Br.*; Jamaica Quassia, Quassia Wood; Bitter Wood; Bitter Ash; Quassie Amère ou Bois amer de Surinam, *Fr. Cod.*; Bois de Quassie, Quassie de la Jamaïque, *Fr.*; Lignum Quassiæ, *P. G.*; Quassiaholz, Fliegenholz, *G.*; Quassia, Quassia della Giammaica, *It.*

"In logs of varying length, or in chips or raspings; yellowish white, tough and dense, but easily split. In longitudinal section, elongated cells containing single crystals of calcium oxalate; in transverse section, medullary rays mostly two or three cells wide. No odor; taste intensely bitter." *Br.*

The genus *Picrasma* is represented by eight species, which are found in the warmer regions of the Old and New World. They all possess a bitter wood and bark.

Picrasma excelsa (Swartz) Planchon (*Picræna excelsa* Lindley), as its name implies, is a lofty tree, sometimes attaining the height of not less than one hundred feet, with a straight, smooth tapering trunk, which is often three feet in diameter near its base, and is covered with a smooth, gray bark. The leaves are pinnate, the leaflets being petiolate and oblong pointed and arranged in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green color, and disposed in panicles. They are polygamous and pentandrous. The

fruit is a small black drupe. This species inhabits Jamaica and the Caribbean Islands, where it is called *bitter ash*. Most of the commercial quassia is obtained from this tree.

Quassia amara, or bitter quassia, is a small branching tree or shrub, with alternate leaves, consisting of two pairs of opposite pinnæ, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep green color on their upper surface, and paler on the under. The common footstalk is articulated and winged. The flowers, which are hermaphrodite and decandrous, are bright red, and terminate the branches in long racemes. The fruit is a two-celled capsule containing globular seeds. *Quassia amara* is a native of Surinam, and is found in Brazil, Guiana, Colombia, Panama, and the West Indies, as also in some tropical countries of the Old World. Its root, bark, and wood were formerly official. They are excessively bitter, as in fact are all parts of the plant. For the botanical description and history of *Quassia amara*, see J. U. Lloyd, *West. Drug.*, 1897, 7; also Gilling (*P. J.*, 1908, lxiii, p. 30).

Properties.—Quassia is at first whitish, but becomes yellow by exposure, and sometimes has blackish spots or markings, due to the presence of the mycelium of a fungus. The two varieties are thus officially described:

"*Jamaica Quassia.*—Usually in chips, raspings or shavings, occasionally in small cubes or billets; yellowish-white or bright yellow, with a few light gray pieces somewhat coarsely grained; fracture tough, fibrous; odor slight; taste bitter. Under the microscope, sections of Jamaica Quassia show large tracheæ either single or in groups of 2 to 5, the walls being marked by numerous, small, bordered pores, and the contents being often of a yellowish color; medullary rays mostly 1 to 5 cells wide and from 10 to 20 rows deep; calcium oxalate, in crystal fibers near the medullary rays, in 4- to 6-sided prisms, from 0.006 to 0.03 mm. in length; wood fibers with thin walls and oblique pores; starch grains few, spherical or ellipsoidal, from 0.01 to 0.015 mm. in diameter.

"*Surinam Quassia.*—The crude drug and microscopic sections closely resemble the Jamaica variety; tracheæ usually single or in pairs, sometimes in groups of 3 or 4; medullary rays in narrower and larger groups than in the Jamaica variety, from 1 to 4 cells wide and from 10 to 30 rows deep; calcium oxalate crystals few or entirely absent, thus distinguishing the variety from Jamaica Quassia." *U. S.*

Quassia imparts its active properties, with its bitterness and yellow color, to water and alcohol. Its virtues depend upon a peculiar bitter crystallizable principle, denominated *quassin*, which was first discovered by Wiggers, who assigned it the formula $C_{10}H_{12}O_3$. Quassin is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the wood. When heated, quassin melts like a resin. It is but slightly soluble in water, 100 parts, at 54° C. (129.2° F.) dissolving only 0.45 part, and that slowly. By the addition of salts, especially of those with which it is associated in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neutral, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, the salts of iron, sugar of lead, or even lead subacetate.

Oliveri and Denaro (*A. J. P.*, 1885, p. 29) obtained quassin in a thoroughly pure, crystallized state, and made a complete study of it. They give it the formula $C_{32}H_{44}O_{10}$. It melts at 210° to 211° C. (410°–411.8° F.), and is very soluble in alcohol, chloroform, and acetic acid, but only sparingly so in ether. Its aqueous solution becomes yellow on exposure to the air, is dextro-rotatory, excessively bitter, and reduces Fehling's solution. When quassin is heated to 90° C. (194° F.) for some hours with diluted sulphuric acid (4 per cent.) it yields *quasside*, $C_{32}H_{42}O_9$, a white, amorphous, bitter substance, formed from quassin by removal of H_2O; no glucose could be detected in the mother liquors. Bromine forms a derivative which seems to have the formula $C_{32}H_{41}Br_3O_9$. If quassin is heated with concentrated hydrochloric acid in sealed tubes for four hours at 100° C. (212° F.), methyl chloride is formed and a colorless substance deposited, which the authors call *quassic acid*, $C_{28}H_{38}O_6(COOH)_2$. This is far less soluble in alcohol than quassin, and crystallizes in silky needles, which melt at 245° C. (473° F.), and reduce Fehling's solution and ammoniacal silver nitrate in the cold. The authors consider quassin as the methyl ether of this quassic acid, as follows:

$$C_{28}H_{38}O_6(COOCH_3)_2 = C_{32}H_{44}O_{10}$$

The real nature of quassin is at present somewhat doubtful, it being probably that distinct substances have been confounded by chemists. Dymock and Warden believe that they have obtained quassin from the wood of *Picrasma quassioides* (Ham.) Benn. of India. According to the researches of Massute (*A. J. P.*, 1890, p. 338), *Quassia amara* contains four principles, which are different from those of *Picrasma excelsa*. By shaking an alcoholic extract of quassia wood with chloroform he obtained a mixture of crystals, from which, eventually, four bitter principles, differing in melting point and solubility, were separated. One of these melting at 210° to 211° C. (410°–411.8° F.), and another melting at 239° to 242° C. (462.2°–467.6° F.), were in too small a quantity to be further examined, but the former agreed in melting point and crystalline form with the quassin of Wiggers ($C_{32}H_{40}O_{10}$). Of the other two, one melted at 215° to 217° C. (419°–422.6° F.), and is represented by the formula $C_{35}H_{48}O_{10}$, while the other melted at 221° to 226° C.

(429.8°–438.8° F.), and is represented by $C_{37}H_{50}O_{10}$. From the wood of *Picrasma excelsa* two crystalline compounds were separated by Massute, both having lower melting points than either of the compounds from *Q. amara.* One was in needles, melted at 204° C. (399.2° F.), and had the composition $C_{35}H_{46}O_{10}$, while the other was in prisms, melted at 209° to 212° C. (408.2°–413.6° F.), and had the composition $C_{36}H_{48}O_{10}$. Both of these are homologues of a third crystalline principle, $C_{29}H_{34}O_{10}$, melting point 212° to 216° C. (413.6°–420.8° F.), which occurs with them. When the *picrasmin,* $C_{35}H_{46}O_{10}$, above referred to, melting at 204° C. (399.2° F.), is heated with hydrochloric acid, it is changed like quassin into an acid, which in this case has the formula $C_{33}H_{42}O_{10} + 5H_2O$, and is called *picrasmic acid.* It appears, therefore, that each wood represents a different series of homologous compounds.

Uses.—Quassia was introduced into medicine about the middle of the 18th century by a negro of Surinam, named Quassi, who acquired considerable reputation in the treatment of the malignant fevers of that country by a secret remedy, which we was induced to disclose to Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756, and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is now comparatively little used, it having been superseded by the product of *Picrasma excelsa* from the West Indies.

Quassia is among the most powerful of the simple bitters, useful in *failure of appetite* due to gastric debility, and in overdoses capable of sufficiently irritating the stomach to produce vomiting. Its active principle, *quassin,* has been studied by Comparden, who asserts that in moderate doses it acts as a stimulant to the salivary, hepatic, and renal secretions, and in overdoses causes burning pain in the œsophagus, with headache, nausea, vertigo, vomiting, diarrhea, and muscular cramps. It is also stated that if given in doses of six-tenths of a grain (0.04 Gm.) before meals it increases markedly the alvine discharges, and that it is especially useful in *constipation* from debility of the muscular and intestinal coats. The dose of pure quassin is three-tenths of a grain (0.02 Gm.).

An infusion of quassia, two ounces in a pint of water, affords a valuable and safe injection for *seat-worms.*

Syrupus Quassiæ.—This syrup is used in the preparation of a harmless fly-poison. Macerate, during twenty-four hours, 1000 parts of quassia wood with 5000 parts of water, then boil for half an hour, set aside for twenty-four hours, and press; mix the liquid with 150 parts of molasses, and evaporate to 200 parts. A weaker decoction of quassia does not kill the flies. From this the *Fly Water* or *Fly Plate* is prepared as follows: Mix when needed, and dispense without filtering, 200 parts of syrup of quassia, 50 parts of alcohol, and 750 parts of water. It is used by moistening with the mixture a cloth or filtering paper on a plate.

Quassia is given in infusion, tincture, extract, or fluidextract. Some *dyspeptic* patients who have become habituated to its bitterness, chew the wood occasionally with benefit.

Dose, five to ten grains (0.32–0.65 Gm.).

QUILLAIÆ CORTEX. Br.

QUILLAIA BARK

(quĭl-lā'ïæ cŏr'tĕx)

"Quillaia Bark is the dried inner part of the bark of Quillaja Saponaria, *Molina.*" *Br.* "The dried bark of *Quillaja Saponaria* Molina (Fam. *Rosaceæ*), deprived of the periderm." *N. F.*

Quillaja, *N.F.*, **Soap-tree Bark;** Soap Bark; Quillaia, *Pharm.* 1880; Panama Bark; Panama (Bois de), *Fr. Cod.;* Ecorce de Quillaya, *Fr.;* Seifenrinde, *G.*

The name of this genus is said to be derived from the popular name of the tree *Quillay,* which in turn comes from the Chilian word *quillean,* to wash.

Quillaja Saponaria Molina is a tree of moderate size, with alternate oval or oblong leaves having entire or slightly denticulate margins. Staminate and pistillate flowers grow on the same branch, are axillary, pedunculate, and without corolla. The calyx of the pistillate flower persists in fruit, and has its limb deeply divided into five oval acute segments. The bark is thick, the wood very hard. This tree was first described by the famous Abbé Giovanni Ignazio Molina in the *Saggio sulla Storia naturale del Chili,* published at Bologna, in 1782; second edition, 1810. (Translated into German, I. D. Brandis, Leipsic, 1786; into French, Gruvel, Paris, 1789; into English, London, 1809; also Middletown, Conn., 1880.) It is first noticed by systematic writers in the second (Gmelin's) edition of the *Syst. Nat.,* tome ii, p. 767. The tree is a native of Peru and Chili, but is now cultivated in Northern Hindostan, where it is said to resist well the frosts of winter, and to be flourishing.

Properties.—Soap bark is officially described in the Br. as "in flat pieces, from three to eight millimetres thick, but varying considerably in length and width. Outer surface brownish-white, or, where the outer bark has been incompletely removed, reddish or blackish-brown, and longitudinally striated. Inner surface white or yellowish-white and smooth. Fracture splintery and laminated, the tangential surfaces of the laminæ often exhibiting glistening prismatic crystals of calcium oxalate. In transverse section, chequered with delicate radial and tangential lines; medullary rays four cells wide; numerous irregular groups of bast fibres of varying size; scattered starch grains from four to six microns in diameter. Powdered Quillaia Bark is strongly sternutatory; *water* vigorously shaken with it forms copious persistent froth.

Odor not marked; taste astringent and acrid. Ash not more than 15 per cent." *Br.*

It is described in the N. F. IV as "in flat pieces of variable length, from 3 to 8 mm. in thickness, or in small chips; outer surface brownish-white, often with small patches of cork attached, otherwise nearly smooth; inner surface yellowish-white, nearly smooth, with occasional circular depressions, conical projections of transverse channels; fracture uneven and strongly fibrous, the laminæ oblique to each other. Odor slight; taste acrid. The powder is strongly sternutatory, and contains calcium oxalate in monoclinic pyramids and prisms from 0.035 to 0.2 mm. in length. Quillaja yields not more than 10 per cent. of ash." *N. F.*

The fracture exhibits, when slightly magnified, glistening prismatic crystals. Quillaja bark is histologically distinguished and its powder recognizable, by the large and numerous prismatic calcium oxalate crystals, which are from 0.035 to 0.200 mm. long.

When bruised and macerated in water quillaja bark imparts to that liquid the property of frothing like soap when agitated. This has been found by Fleury, Jr., and Boutron-Chalard to be owing to the existence of a *saponin* in the bark. The bark contains neither tannic acid nor any bitter principle. The formula of saponin, given by Rochleder, was $C_{32}H_{54}O_{18}$, and Schiaparelli agreed with him. Stütz, however (*Ann. Ch. Ph.*, 218, 231), gives it as $C_{19}H_{30}O_{10}$, and this is now accepted for the saponin of quillaja bark. Saponin is slowly decomposed by dilute acids into *sapogenin*, $C_{14}H_{22}O_2$, and a glucose. R. Kobert (*Chem. Central.*, 1893, i, 32) gives a list of one hundred and forty plants which contain bodies of the saponin class. He arranges them under several formulas which seem to form an homologous series. Thus, $C_{17}H_{26}O_{10}$ he terms Saponin I (*senegin* or *quillaia sapotoxin*); $C_{18}H_{28}O_{10}$ is Saponin II (Schmiedeberg's *digitonin* or *saprorubrin*); $C_{19}H_{30}O_{10}$ is Saponin III (*quillain* or *quillaiac acid*); $C_{20}H_{32}O_{10}$ is *cyclamin*, Paschki's *digitoxin*, or *sarsaparillsaponin;* $C_{22}H_{36}O_{10}$ is *sarsa-saponin;* $C_{26}H_{44}O_{10}$ is *parillin.*

G. Melliers states that there is present in quillaja bark a carbohydrate which he has identified as *saccharose.* (*P. J.*, Feb., 1901, 161.)

Uses.—In diluted form quillaia saponin is irritant to all tissues, and when concentrated it kills by its local action both muscular and nervous tissue. As was first discovered by H. Köhler, when injected into the leg of the frog in minute quantity it produces not only motor weakness but a rapid loss of sensibility, so that reflex movements can no longer be caused by irritating the foot. The paralysis seems to affect especially the peripheral nerve endings, since irritation of the nerve trunk, although incapable of causing contraction of the muscles supplied by it, elicits pain, cries and other evidences of sensibility. Muscles with which saponin comes in contact become unexcitable and pass into a condition resembling post mortem rigidity. According to Köhler, this occurs without change in the microscopic structure, but Przybyszewski found that in the neighborhood of the injection where the saponin was abundant the muscles underwent structural changes similar to those of myositis. In the frog saponin produces not only local symptoms, but after a time widespread paralysis, with final arrest of the cardiac movements. Given internally to mammals it causes violent gastro-intestinal irritation, progressive loss of power, disturbance of respiration and circulation, and usually clonic and tonic convulsions, which are probably secondary to the perturbations of the cardiac and respiratory functions.

Injected into the circulation in rabbits and dogs, according to the researches of Przybyszewski, it causes fall of the arterial pressure, with great disturbance of the respiration and finally cardiac arrest. According to Köhler, the action of the drug upon the heart is antagonistic to that of digitalin, so that the application of sufficient quantities of saponin to the frog's heart which has been arrested by the local application of digitalin will bring about a return of pulsations, while, on the other hand, digitalin is capable of putting aside cardiac arrest from saponin. As has been shown by Ransom (*D. M. W.*, xxvii), saponin has a powerfully destructive action upon the red blood corpuscles, due to an extraordinary tendency which it has to unite with their cholesterin. The action of saponin upon the respiratory centres is very great, the injection of large doses being followed by immediate arrest of respiration, the heart continuing to beat for some time. As it exists in agrostemma seeds, saponin has several times caused death in the human species. The symptoms have been headache, vertigo, vomiting, hot skin, rapid feeble pulse, progressive muscular weakness, and finally coma. Following out the experiments of Kobert, Ulenburg and Keppler tried saponin as a local anesthetic, but found that it was not practically convenient for use; nor were the essays of Kobert with the glucoside as an antipyretic more encouraging.

According to Kobert (*Gaz. Méd. de Paris*, xiv, 2, 1883), saponin of commerce is composed chiefly of two substances, *quillaic acid* and *sapotoxin.* For method of preparation, see *T. G.*, vol. ii, 540. The quillaic acid is said to be extraordinarily poisonous, three-one-thousandths of a grain for each pound of body weight injected into the veins of a cat being sufficient to cause death, although thirty grains administered by the mouth are safely borne. Lohmann (*P. J.*, 73, 477) affirms that chemically pure saponin is not injurious when taken by the stomach.

Both the active principles, quillaiac acid and sapotoxin, of quillaja bark are violent local irritants. In a case of poisoning by quillaiac acid (*T. G.*, xi) the symptoms were violent vomiting, with epigastric pain, increased diuresis and cystic irritation, accompanied by cold sweats, feeble pulse, threatened syncope, and other evidences of collapse.

Sapotoxin, when in sufficient concentration and amount, is a fatal poison to all forms of protoplasm. Given to the lower animals in very large toxic dose it produces violent convulsions with death from failure of the respiration. When in smaller quantities it causes violent *dysenteric diarrhea*, with ecchymotic hyperæmia, œdema, and necrotic destruction of the intestinal mucous membrane. The smallest lethal doses are said to produce great weakness, death occurring after some days through collapse and general paralysis without intestinal symptoms. In such cases, when the drug is administered hypodermically, a severe hemorrhagic inflammation occurs at the place of injection. Fatty preparations of sapotoxin applied to the sound skin produce redness and burning with, after repeated applications, painful pustulation. Both sapotoxin and quillaiac acid have the power of breaking down the red blood corpuscles, but it is not apparent that such destruction plays an important *rôle* in poisoning by these substances except at the point of injection after hypodermic use.

On account of the active principles of soap bark being the same as those of senega, and to some extent of sarsaparilla, Kobert has proposed the use of quillaja as a cheap substitute for these much used drugs. As a stimulating expectorant he uses a decoction (five parts to two hundred) in doses of a tablespoonful for the adult. As a substitute for syrup of senega Power suggests the *syrup of quillaja*, prepared by adding four parts of the fluidextract (made by the process for fluidextract of arnica root, see p. 524) to sufficient syrup to make twenty-five parts. (*P. J.*, Oct., 1886.)

Quillaja is much used in the arts for washing silk, cloth, and other fabrics, for which soap would not be suitable. It is an emulsifying agent, but unless ordered by the physician should never be used by the pharmacist in the preparation of emulsions, on account of its active medicinal properties.

It has also been largely used in the production of foam on non-alcoholic carbonated beverages. This use has been criticized as harmful and it is now prohibited by law in many jurisdictions.

Off. Prep.—Liquor Picis Carbonis, *Br.*; Tinctura Quillajæ, *N. F.* (*Br.*).

QUININA. U. S.

QUININE Quin.

(quĭ-nĭ'nă)

"An alkaloid [$C_{20}H_{24}O_2N_2 + 3H_2O = 378.26$] obtained from the bark of various species of *Cinchona* (Fam. *Rubiaceæ*). Preserve it in well-closed containers, protected from light." *U. S.*

Chininum; Quinine Hydratée, *Fr. Cod.*; Chinin, *G.*; Chinina, *It.*; Quinina, *Sp.*

This alkaloid is prepared by adding to a solution of quinine sulphate a quantity of ammonia water or solution of sodium hydroxide just a sufficient quantity to cause a precipitation of the alkaloid.

Properties.—Quinine is whitish, rather flocculent, and usually not crystalline; it may with care be crystallized from its alcoholic solution in silky needles, and Liebig obtained it from a somewhat ammoniacal aqueous solution in the same form. It is inodorous and very bitter. The crystals obtained from alcoholic solution have the composition $C_{20}H_{24}O_2N_2 + 3H_2O$, and fuse at 57° C. (134.6° F.). They may be deprived of water by warming or exposure over sulphuric acid, and they then fuse at 171.2° to 172° C. (340°–341.6° F.). By carefully regulated heat, it may be sublimed unchanged, assuming a crystalline form. (Waddington, *P. J.*, March, 1868, p. 413.) According to Hesse, anhydrous crystalline quinine is soluble in 1960 parts of water at 15° C. (59° F.), and the trihydrate in 1670 parts. It is soluble in about 900 parts of boiling water, in about 6 parts of cold and in 2 parts of boiling alcohol, very soluble in ether, chloroform, benzene, petroleum benzin, carbon disulphide, fixed and volatile oils, and in about 200 parts of glycerin. The alcoholic solution is intensely bitter. Quinine is unalterable in the air. It forms salts with the acids which readily crystallize. The tannate, tartrate, and oxalate are said to be insoluble or nearly so, but are dissolved by an excess of acid. The acetate is so slightly soluble that it is precipitated from a solution of the sulphate by magnesium acetate and the other acetates. (*A. J. P.*, xxx, 386.) When recently precipitated quinine, diffused in water, is exposed to the action of a stream of carbon dioxide, the quinine is dissolved, and, if the solution be exposed, acicular crystals of quinine carbonate will be deposited, which effloresce in the air, are soluble in alcohol, but insoluble in ether, have an alkaline reaction, and effervesce with acids. After the deposition of the crystals has ceased, the solution yields quinine on evaporation. (Langlois, *C. R. A. S.*, Nov. 7, 1853, 727.) Freshly precipitated quinine is scarcely soluble to an appreciable extent in an excess of potassium hydroxide, but is more readily dissolved by ammonia. (Wadgymar, *A. J. P.*, Sept., 1866, 451.) Flückiger (1878) noticed that solutions of quinine exposed to sunlight rapidly turned brownish-yellow, and subsequently deposited a flocculent precipitate, which he proved to be neither quinine nor quinicine, but an entirely different substance. It had lost the alkaloidal character, yet possessed the same chemical composition as quinine. He named it *quiniretin*. (*P. J.*, May, 1878.)

Quinine and its salts may be distinguished from all other alkaloids and their salts, except only quinidine and quinicine, by the beautiful emerald-green color (*thalleioquin*) which reults when their solution is treated first with solution of chlorine and then with ammonia, and which changes to a white or violet upon saturation with a dilute acid. The statement which has been frequently made that the chlorine water must be fresh, was disproved by C. F. Zeller, but it has been repeatedly observed that the reaction is inhibited by the presence of even minute

amounts of free inorganic acids and the compound solution of chlorine, made by reacting upon potassium chlorate with hydrochloric acid and then diluting with water, cannot be used to replace chlorine water made by the older process. The reaction with bromine water is much more delicate and satisfactory. (See *A. J. P.*, 1880, p. 385.) The least quantity of quinine may be detected by powdering the substance supposed to contain it, then shaking it with ether, and adding successively the tests just mentioned. Quinine in aqueous solution turns the plane of polarization to the left, to varying degrees, however, according to the concentration, the solvent used, etc. Acids increase the amount of deviation. In relation to the property possessed by quinine of imparting fluorescence to its aqueous solution, which is possessed also, though in less degree, by other cinchona alkaloids, and other properties common to both quinine and its sulphate, there will be occasion to speak under quinine sulphate. A singular discovery was made by Bence Jones of London, of a substance normally present in the animal system having analogous properties, and named by him "*animal quinoidine.*"

Quinine is officially described as "a white, micro-crystalline powder; odorless, having a bitter taste, developing rather slowly, but intense and persistent; efflorescent in dry air. One Gm. of Quinine dissolves in 1560 mils of water, 0.8 mil of alcohol, 1.1 mils of chloroform, 1.9 mils of ether, and in 1890 mils of ammonia water at 25° C. (77° F.); also in 800 mils of boiling water. Its alcoholic solution (1 in 10) is lævorotatory and alkaline to litmus. A solution of Quinine in diluted sulphuric acid shows a vivid blue fluorescence. Add 2 or 3 drops of bromine T.S. to 1 mil of an aqueous solution of Quinine (1 in 100) made with the aid of just sufficient diluted sulphuric acid to effect solution, and then add 1 mil of ammonia water; the liquid acquires an emerald-green color due to the formation of thalleioquin. Quinine loses not more than 15 per cent. of its weight when dried to constant weight at 100° C. (212° F.). Incinerate about 1 Gm. of Quinine; not more than 0.1 per cent. of ash remains. A solution of about 0.1 Gm. of Quinine in 2 mils of sulphuric acid is not darker than light yellow (*organic impurities*). This solution is not colored red on the subsequent addition of a few drops of nitric acid (*morphine*). Heat about 0.2 Gm. of Quinine with 2 mils of potassium hydroxide T.S.; the odor of ammonia is not evolved (*ammonium salts*). Dissolve 1.74 Gm. of Quinine in 20 mils of alcohol, dilute the solution with 50 mils of hot distilled water and neutralize it with normal sulphuric acid V.S., using methyl red T.S. as indicator. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 mils of distilled water and complete the test for other cinchona alkaloids as directed under *Quininæ sulphas.*" *U. S.*

Quinicine (*quinicia*).—When quinine and cinchonine, or quinidine and cinchonidine, or their salts, are exposed to heat, they are changed into isomeric alkaloids—quinine and quinidine into *quinicine,* and cinchonine and cinchonidine into *cinchonicine,* each isomeric with its own antecedents. These new alkaloids are, therefore, products rather than educts, and generally result, in greater or less proportion, from the processes employed in extracting the other alkaloids from bark, though it is not impossible that they may pre-exist in bark to a certain extent, being formed by a natural process, from the same original alkaloids, either in the living tree, or in the barks while drying, after separation from the tree. *Quinicine* is almost insoluble in water, but very soluble in alcohol, and differs from quinine in being dextro-rotatory and uncrystallizable. *Cinchonicine* is also insoluble in water and soluble in alcohol. It agrees with cinchonine, from which it is derived, in producing deviation of the plane of polarization to the right, but differs from cinchonidine in this respect, and differs from both in being amorphous or uncrystallizable.

The study of the decomposition products of quinine and associated alkaloids so actively carried on for several years past has thrown considerable light upon its composition. It appears to be a derivative of a partially hydrogenized diquinoline, corresponding to the formula $C_9H_6(OCH_3)N$ — $C_9H_{11}(OH)N.CH_3$. By oxidation with chromic acid it yields *quininic acid,* $C_9H_5(OCH_3)N.COOH$, which is the phenol ester of cinchoninic acid, $C_9H_6N.COOH$; by oxidation with nitric acid it yields *cinchomeronic acid,* $C_5H_3N(COOH)_2$; by the action of potassium hydroxide it yields *methoxyquinoline,* $C_9H_6N(OCH_3)$. For a summary of our knowledge upon the constitution of quinine and cinchonine, see *Guareschi's Einführung in das Studium der Alkaloide,* translated by H. Hermann Kunz-Krause, Berlin, 1896, 524, *et seq.*

The most important salt of quinine is the *sulphate,* the process for procuring which, as well as its properties, will be hereafter described. Besides the salts which are official, the *phosphate, acetate, citrate, lactate, camphorate, ferrocyanide, arsenite, antimonate, urate, hypophosphite, chlorate, citro-thymate, sulphovinate, sulpho-salicylate,* and *meconate,* have also been employed or recommended, but none of them has yet gained admittance into the Pharmacopœias, and none probably is superior to the official salts. The first four may be prepared by saturating a solution of the acids respectively with quinine, and evaporating the solutions. The *camphorate* is recommended as a substitute for the valerate. (*A. J. P.*, July, 1865, p. 254.) The *ferrocyanide* is directed to be made by boiling together four parts of quinine sulphate and one of potassium ferrocyanide, both in concentrated solutions, pouring off the liquor from a greenish-yellow substance of an oily consistence which is precipitated, washing the latter with distilled water, then dissolving it in strong alcohol at 37.7° C. (100° F.), filtering immediately, and afterwards evaporating the solution. Pelouze believes this prep-

aration to be pure quinine, mixed with a little Prussian blue. (*A. G. M.*, 3e sér., xv, 236.)

Quinine arsenite has been recommended by Ringdon, especially in chronic cutaneous affections. Alder prepares it by dissolving arsenic trioxide in water, with enough alkali to make the solution neutral, adding about five times its weight of silver nitrate, washing the precipitated silver arsenite, drying, and mixing with three times its weight of quinine hydrochloride, digesting the mixture for a day with 70 per cent. alcohol, filtering, and allowing the filtrate to evaporate spontaneously. The salt is crystalline, soluble in alcohol, chloroform, and ether, but sparingly so in water. The dose is one-third of a grain (0.021 Gm.), given at first twice a day, and afterwards three or four times a day. *Quinine antimonate* has been recommended by La Camera, of Naples, as a febrifuge, being especially applicable to cases of doubtful periodicity. It unites, he thinks, the evacuant properties of the antimonials with the antiperiodic property of quinine. The dose is two or three grains (0.13 or 0.20 Gm.), four times a day. (*J. P. C.*, 3e sér., xxv, 471.) *Quinine urate* is thought by Pérayre of Bordeaux, to be peculiarly efficacious in obstinate intermittents. It is prepared by boiling 10 parts of crude quinine in water, adding gradually 20 parts of crystallized uric acid, and, after sufficient ebullition, filtering and evaporating. A yellow salt is obtained, sometimes amorphous, more frequently crystalline, soluble in hot and less so in cold water, and, according to the author, capable of curing intermittent fever in smaller doses than the sulphate, with less cerebral disturbance, less bitterness, and easier tolerance by the stomach. (*J. P. C.*, 3e sér., xxxvii, 139.) *Quinine hypophosphite* may be prepared by dissolving 3 parts of calcium hypophosphite in 60 parts of distilled water, and adding the filtered solution to a solution of 13 parts of quinine sulphate in 200 parts of alcohol, allowing the mixture to stand two hours, and filtering, distilling off the alcohol and evaporating the solution and setting aside to crystallize. The salt is soluble in 25 parts of cold water, in 1.5 parts of boiling water, and in 10 parts of alcohol. *Quinine glycerophosphate* exists in two conditions, basic and neutral. The basic salt, which is stable, may be made by dissolving 75.6 Gm. of quinine in 500 mils of ether and mixing with a solution of 17.2 Gm. of glycerophosphoric acid in 60 Gm. of alcohol (95 per cent.), collecting the white precipitate, washing with ether, and drying. (E. Fallières, *P. J.*, 1898, 410.)

Quinine citro-thymate is prepared by Pavesi by heating in a flask on a water bath 4 parts of quinine and 6 parts of oil of thyme, with enough alcohol to dissolve both. After standing 12 hours, 2 parts of powdered citric acid are added, and the whole heated, filtered, evaporated, and allowed to crystallize. For processes for making other quinine salts, see *U. S. D.*, 19th edition, page 1039.

Uses.—In sufficient concentration quinine appears to be poisonous to all forms of protoplasm, as well of the unicellular micro-organisms as of the more highly organized tissue of man. Among the unicellular organisms, in a general way the protozoa are more susceptible than the bacteria, but the drug is peculiarly poisonous to the plasmodia of malaria. In the frog moderate doses of quinine cause a diminution in the reflex activity which is generally attributed to a stimulation of the spinal inhibitory center, commonly known as Setschenow's center. Larger quantities are directly depressant to the motor ganglia. In mammals it frequently gives rise to convulsions, which appear to be due to irritation of the motor area of the brain. Locally applied it is paralyzing to both the motor and sensory nerves, but especially to the latter. In moderate dose it has no demonstrable influence upon the circulation, but large quantities—equivalent to 75 or 80 grains for man—are depressant to the heart. It increases the vigor of the contractions of the voluntary muscles, but apparently lessens resistance to fatigue. According to Cushny, it is a direct stimulant to the uterine muscle, increasing the force of the contractions but not greatly affecting the tonus.

As was shown many years ago by Binz, when added to the blood outside the body in the proportions of about 1 part in 4000, it caused an immediate cessation of the amœboid movements of the white corpuscles. This effect is probably simply one of the manifestations of its general protoplasmic toxicity, and plays little part in its therapeutic action. According to Roth (*J. P. Ex. T.*, 1912, iii, p. 470), it causes a pronounced leukocytosis; at first there is an increase in the number of lymphocytes which he believes is due to contraction of the spleen and lymphatic tissues, but later there is an increase in the number of polymorphonuclear cells. According to De Sandro (*Rif. M.*, 1910), the continued use leads to an increase in the number of both red and white cells in the blood.

Quinine appears to have a powerful influence in lessening the rapidity of catabolism in the body. The evidence in favor of this view is three-fold: first is the well-established fact of diminished excretion of nitrogenous waste products with the urine under its influence; secondly, the observations of Senta (*A. I. P. T.*, xviii, p. 217), who has found a diminution in the absorption of oxygen and gaseous exchange of isolated bits of muscles; and thirdly, its effects upon bodily temperature. Although in normal man ordinary doses do not cause a reduction of temperature, yet they prevent the natural rise of temperature which takes place after violent exercise and in febrile patients often gives rise to distinct lowering.

Quinine is used in medicine for a large variety of purposes. The oldest and most important of these is for the treatment of *malarial fevers*, for which disease it is by far the most reliable remedy that we possess. While the curative value of the drug is universally acknowledged there is some difference of opinion as to its usefulness as a prophylactic against this disease, but despite the contrary results of

Stitt (*J. A. M. A.*, 1908, i, p. 1682), we are inclined to believe in its usefulness.

In various infectious fevers, such as *pneumonia, septicemia,* or *typhoid fever,* it has been widely employed, not merely as an antipyretic, but in the thought that it has a direct influence in lessening the growth of pathogenic bacteria in the body. In *pneumonia* there is reason to believe, although not definitely established, that quinine directly inhibits the growth of the pneumococci in the body. It is probable that the well-known curative action of the drug in *acute coryza* is attributable to some influence upon the causative infection of this common complaint. Moon (*Journ. of Infectious Diseases,* 1913, xiii, p. 165) presented evidence of a curative effect in hydrophobia in dogs, but his results have been called in question by Cumming (*Journ. of Infectious Diseases,* 1914, xv) and by Frothingham and Halliday (*Journ. Med. Research,* 1914, xxx). It appears also to be of use in *whooping-cough.*

Because of its restraining effect upon destructive metabolism as well as its effect as a bitter upon the stomach, quinine is a valuable remedy in the treatment of various form of *malnutrition.* In *Graves's disease* it appears to have an effect not merely in restraining the excessive catabolism which is characteristic of this disorder, but also to have a general sedative influence on the nervous system. Some years ago on the theory that *chorea* was due to a lack of spinal inhibition H. C. Wood suggested the use of quinine in the treatment of this disorder, and in many cases it has proven of marked benefit. Through a similar line of reasoning its use was extended to the treatment of *nocturnal enuresis.* It is also recommended as an internal remedy by a number of authors in the treatment of various forms of skin disease, especially *psoriasis* and *urticaria;* in *lupus erythematosus* it has been used both internally and locally.

Brooke (*J. A. M. A.*, 1914, lxii) experimentally determined that quinine sulphate would kill amœba in solutions of 1 to 20,000, and employed it in the form of enemata in the treatment of amœbic *dysentery* with satisfactory results.

Quinine possesses marked local anesthetic powers and has come into considerable use as a substitute for cocaine. For this purpose the hydrochloride of quinine and urea is generally preferred. (See page 934.)

Because of the insolubility of basic quinine it was formerly believed that the alkaloid was absorbed only from the stomach, but Grosser (*Biochem. Zeit.*, viii, 1907–1908, p. 98) has shown that even the insoluble preparations are completely absorbed. Apparently much of the drug is destroyed in the body as various investigators have succeeded in recovering only from 40 to 60 per cent. of the ingested dose from the excreta. According to Kerner, a portion escapes in an amorphous uncrystallizable form, and a second portion as a substance free from bitter taste, though crystallizable and having the fluorescence of quinine; for this substance he has proposed the name of *dihydroxyl-quinine.*

Elimination seems to be freest between the sixth and twelfth hours, and about two-thirds of that which is recovered from the urine is excreted within twenty-four hours of its ingestion.

The dose of quinine varies greatly according to the purpose for which it is used, as well as the susceptibility of the patient. When used for its tonic effect from three to five grains (0.2–0.32 Gm.) may be given three or four times a day. The antipyretic dose is from fifteen to twenty grains (1.0–1.3 Gm.). S. Solis Cohen has administered, in *pneumonia* with asserted good effects, twenty-five to thirty grains hypodermically (1.7–2.0 Gm.). In the milder forms of *malaria,* such as the ordinary *tertian fever* of temperate climates, from five to ten grains may be given every hour until the patient has taken twenty or thirty grains, and so timed that the last dose comes about an hour before the expected chill. In the tropical varieties of malaria, however, very much larger quantities are required, and in malignant types many authorities recommend to give as high as seventy-five to one hundred grains (5.0–6.5 Gm.) immediately. Such doses cannot be administered by mouth because they are likely to provoke emesis, and moreover, absorption is so slow as to be dangerous in these pernicious fevers. Under such circumstances the quinine may be given hypodermically. The most soluble of the official salts is the dihydrochloride, and by many is the salt of choice for injection, but it is likely to prove irritant because of its acid reaction. The double hydrochloride of quinine and urea is neutral in reaction and is soluble in less than its own weight of water; the 50 per cent. solution may be employed. If injected immediately beneath the skin, solutions of quinine salts are liable to produce local necrosis and ulceration and therefore should always be injected into the muscle substance either in the lumbar or gluteal regions. Extreme care in asepsis is essential in making these injections. A number of cases of *tetanus* have followed the injections of quinine, but McCampbell (*J. A. M. A.*, March 16, 1907) from his experiments concludes that there is no peculiar relation between the quinine and the tetanus germs, except that the spores may be carried in mechanically with the injection and the local necrosis offers a favorable place for their growth.

Toxicology.—Even in the quantities employed for therapeutic purposes quinine frequently produces unpleasant symptoms. The most common of these is ringing in the ears often accompanied with a sensation of fullness in the head, and perhaps some obtunding of the sense of hearing. With the use of larger doses these symptoms are intensified: the deafness is very marked, disturbed vision may exist, and the flushed face, with the sense of distension in the head, may point towards a cerebral congestion, which is in some cases relieved by spontaneous epistaxis. In decided cinchonism, giddiness and staggering in walking are very common. After toxic doses, severe headache, delirium, stupor,

complete deafness and blindness, dilated pupils, embarrassment of respiration, great weakness, convulsions, paralysis, and finally collapse, either comatose or delirious, may result. The deafness produced by large doses of quinine usually passes off rapidly; very rarely is there a permanent impairment of hearing. Amaurosis, with a peculiar ischemia of the retinal vessels, has in a small number of cases been produced by very large therapeutic doses of the alkaloid. Besides its effects on the brain, quinine sulphate sometimes occasions great gastric and intestinal irritation, marked by oppression of stomach, nausea, abdominal pains, vomiting, and purging. In general, these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer, and permanent deafness has resulted. It is capable of taking life, although enormous amounts of it are requisite for this. Several cases of recovery are recorded after the taking of an ounce by the stomach. Probably only a portion of the drug was absorbed. Five ounces taken in ten days have caused death.

In certain individuals even very small doses may produce toxic symptoms. In these cases the poisoning usually differs very markedly from the ordinary type described above, in most instances being manifest by eruptions on the skin which frequently closely simulate scarlet fever. (See H. C. Wood, Jr., *T. G.*, January, 1902.)

Dose, two to twenty grains (0.13–1.3 Gm.).

QUININÆ BISULPHAS. U. S.

QUININE BISULPHATE Quin. Bisulph.

(quĭ-nī′næ bī-sŭl′phăs)

"The acid sulphate [$C_{20}H_{24}O_2N_2.H_2SO_4 + 7H_2O = 548.41$] of the alkaloid quinine. Preserve it in well-closed containers, protected from light." *U. S.*

Chininum Bisulfuricum, Quininæ Sulphas Acidus; Acid Quinine Sulphate; Sulfate de Quinine Neutre, *Fr. Cod.*; Saures Chininsulfat, Chininbisulfat, *G.*; Bisolfato di chinina, *It.*; Sulfato quinico neutro, *Sp.*

This salt is made by suspending 100 Gm. of quinine sulphate in 500 Gm. of warm distilled water, and adding 115 Gm. of diluted sulphuric acid (U. S. P.), filtering and crystallizing. It has been introduced because of the great advantages in solubility that it possesses over the ordinary sulphate. It requires but 8.5 parts of water to dissolve it, while the sulphate requires 720. It is officially described as in "colorless, transparent, or whitish, orthorhombic crystals or small needles; odorless, and having a very bitter taste. It effloresces on exposure to air, and turns yellow on exposure to light. One Gm. of Quinine Bisulphate dissolves in 9 mils of water, 23 mils of alcohol, 15 mils of glycerin, 625 mils of chloroform and in 2500 mils of ether, at 25° C. (77° F.); also in 0.7 mil of boiling water and 0.7 mil of alcohol at 60° C. (140° F.). Its aqueous solution (1 in 20) is strongly acid to litmus and has a blue fluorescence. Add 1 or 2 drops of bromine T.S. to 1 mil of an aqueous solution of Quinine Bisulphate (1 in 100) and then add 1 mil of ammonia water; the liquid acquires an emerald-green color due to the formation of thalleioquin. Barium chloride T.S. added to an aqueous solution of the salt produces a white precipitate, insoluble in hydrochloric acid. Quinine Bisulphate loses not more than 25 per cent. of its weight when dried to constant weight at 100° C. (212° F.). Incinerate about 2 Gm. of Quinine Bisulphate; not more than 0.05 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is not darker than light yellow (*organic impurities*). This solution is not colored red by the subsequent addition of a few drops of nitric acid (*morphine*). Dissolve 2.52 Gm. of Quinine Bisulphate in 50 mils of hot distilled water and neutralize the solution with normal sodium hydroxide V.S., using methyl red T.S. as indicator. Evaporate the solution to dryness on a water bath, powder the residue, mix it in a test tube with 20 mils of distilled water and complete the test for other cinchona alkaloids as directed under *Quininæ Sulphas." U. S.*

The acid sulphate of quinine is much more freely soluble than the neutral sulphate and is therefore by many preferred. It has, however, no very real advantage, being inferior for hypodermic injection to the dihydrochloride or the double hydrochloride of quinine and urea because of its lesser solubility, and when given by the mouth the slight increase in solubility over the neutral salt is a matter of small importance. It represents about 80 per cent. of the amount of quinine in the neutral sulphate.

Dose, two to fifteen grains (0.13–1.0 Gm.).

QUININÆ DIHYDROCHLORIDUM. U. S. (Br.)

QUININE DIHYDROCHLORIDE Quin. Dihydrochl.

(quĭ-nī′næ dī-hȳ-drŏ-klō′rīd-dŭm)

"The dihydrochloride [$C_{20}H_{24}O_2N_2.2HCl = 397.15$] of the alkaloid quinine. Preserve it in well-closed containers, protected from light." *U. S.* "Acid Quinine Hydrochloride, $C_{20}H_{24}N_2O_2,2HCl$, is the acid hydrochloride of an alkaloid, quinine, obtained from the bark of various species of Cinchona." *Br.*

Quininæ Hydrochloridum Acidum, *Br.*, Acid Quinine Hydrochloride; Chlorhydrate de Quinine Neutre, *Fr.*; Saures Chininhydrochlorid, Saures Chlorwasserstoffsaures Chinin, *G.*

This was an official quinine salt of the Br. Pharm., 1898. It was introduced into the U. S. P. IX, and retained in the Br., 1914. It has been introduced on account of its remarkable solubility in water—*i.e.*, less than its own weight. It may be made by passing hydrochloric acid gas over dry quinine, but more conveniently by decomposing quinine bisulphate with barium

chloride or by mixing a solution of neutral hydrochloride with one molecular proportion of hydrochloric acid and evaporating the solution at a gentle heat. It is officially described as "a white powder, odorless, and having a very bitter taste. One Gm. of Quinine Dihydrochloride dissolves in about 0.6 mil of water and in 12 mils of alcohol at 25° C. (77° F.); it is slightly soluble in chloroform and very slightly soluble in ether. Its aqueous solution (1 in 20) is strongly acid to litmus. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 20) produces a white precipitate, insoluble in nitric acid. Add 1 or 2 drops of bromine water T.S. to 1 mil of an aqueous solution of the salt (1 in 100) and then add an excess of ammonia water; an emerald-green color is produced due to the formation of thalleioquin. Incinerate about 2 Gm. of Quinine Dihydrochloride; not more than 0.05 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is not darker than yellow (*readily carbonizable impurities*). Ten mils of an aqueous solution of the salt (1 in 50) is not rendered more than faintly turbid by the addition of a few drops of barium chloride T.S. (*sulphate*). The addition of a few drops of diluted sulphuric acid to 10 mils of an aqueous solution of the salt (1 in 20) produces no turbidity (*barium*). Dissolve 1.8 Gm. of Quinine Dihydrochloride in 10 mils of distilled water, add a slight excess of ammonia water and extract the precipitate by shaking the mixture with three successive portions of 20, 10 and 10 mils each of chloroform. Evaporate the combined chloroform extracts to dryness on a water bath, dissolve the residue in 25 mils of alcohol, dilute it with 50 mils of hot distilled water and neutralize the liquid with normal sulphuric acid V.S., using methyl red T.S. as indicator. Now evaporate the liquid to dryness on a water bath, powder the residue, mix it with 20 mils of distilled water in a test tube, and complete the test for other cinchona alkaloids as directed under *Quininæ Sulphas.*" *U. S.*

"A white amorphous powder. No odor; taste intensely bitter. Soluble in less than 1 part of *water*. Aqueous solution acid to *litmus*. Yields the *reactions* characteristic of chlorides. Yields not more than the slightest characteristic *reaction* for sulphates. 1 gramme dissolved in 20 millilitres of *water* requires for neutralisation not more than 5.0 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields a green coloration when tested as described under 'Quininæ Hydrochloridum.' Loses not more than 3 per cent. of its weight when dried at 100° C. (212° F.). When 2 grammes are dissolved in 15 millilitres of *water*, the solution neutralised with *N/1 solution of sodium hydroxide*, mixed with 1 gramme of powdered non-effloresced *sodium sulphate*, and further treated as described under 'Quininæ Hydrochloridum,' the precipitate produced on the addition of *solution of ammonia* redissolves on rotating the tube (limit of other cinchona alkaloids). No appreciable ash." *Br.*

Uses.—The dihydrochloride is the most freely soluble of the official salts of quinine. For this reason it is frequently preferred for hypodermic injection. Because of its acid reaction, however, it is more likely to produce local irritation than the neutral salts.

Dose, two to ten grains (0.13–0.65 Gm.).

QUININÆ ET UREÆ HYDROCHLORIDUM. U. S.

QUININE AND UREA HYDROCHLORIDE Quin. et Urea. Hydrochl. [Quinine and Urea Chloride]

(quĭ-nī'næ ĕt ū-rē'æ hȳ-drŏ-ȼhlō'rĭ-dŭm)

"A compound of the hydrochlorides of quinine and urea [$C_{20}H_{24}O_2N_2.HCl.CO(NH_2)_2.HCl + 5H_2O = 547.28$] which contains not less than 58 per cent. of anhydrous quinine. Preserve it in well-closed containers, protected from light." *U. S.*

Quinine and Urea Muriate, Chininum Bimuriaticum Carbamidatum.

This salt was discovered by Kutais (1878), is best prepared by Rice's process. Seventy-nine parts of quinine hydrochloride are dissolved in 70 parts of hydrochloric acid (sp. gr. 1.050), the solution filtered, 12 parts of urea added, and the whole warmed until the liquid is clear. It is then set aside, that crystals may form. These are soluble in an equal weight of water, and also in strong alcohol, and are usually purified by recrystallization.

"Quinine and Urea Hydrochloride occurs in colorless, translucent prisms or as a white, granular powder; odorless, and having a very bitter taste; permanent in the air. One Gm. of Quinine and Urea Hydrochloride dissolves in 0.9 mil of water and in 2.4 mils of alcohol at 25° C. (77° F.). An aqueous solution of the salt (1 in 20) is strongly acid to litmus. Silver nitrate T.S. added to an aqueous solution of the salt produces a white precipitate, insoluble in nitric acid. Add 2 mils of colorless nitric acid to a cold solution of about 1 Gm. of the salt in 2 mils of distilled water and cool the mixture at once at the temperature of melting ice. Crystalline leaflets of urea nitrate are formed on standing. Collect the crystals in a funnel upon glass wool, wash them with about 5 mils of a cold mixture of equal volumes of nitric acid and distilled water, and, after draining them, dissolve the crystals in a few mils of distilled water. The addition of a few drops of mercuric nitrate T.S. to the urea nitrate solution, followed by sodium hydroxide T.S., to only a slightly acid reaction, produces a white precipitate. Incinerate about 2 Gm. of Quinine and Urea Hydrochloride; not more than 0.05 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is not darker than light yellow (*readily carbonizable matter*). Warm 10 mils of an aqueous solution of the salt (1 in 20) with 5 mils of sodium hydroxide T.S. to 50° C. (122° F.); the odor of ammonia is not evolved at once (*ammonium compounds*). The quinine obtained by precipitating 60 mils

of an aqueous solution of the salt (1 in 20) with sodium hydroxide T.S., washing it on a filter with cold distilled water until the washings give only a faint opalescence with silver nitrate T.S., and then drying it at about 50° C. (122° F.), responds to the test for identity, and 1.5 Gm. of it conforms to the requirement regarding other cinchona alkaloids under *Quinina.*

"**Assay.**—Weigh accurately about 0.5 Gm. of Quinine and Urea Hydrochloride, dissolve it in 5 mils of distilled water in a separator, then add 5 mils of potassium hydroxide T.S., and shake the mixture with successive portions of 10, 5 and 5 mils, respectively, of ether or sufficient to completely extract the quinine. Upon evaporation of the combined ether-extracts and drying to constant weight at 100° C. (212° F.), the residue of anhydrous quinine corresponds to not less than 58 per cent. of the weight of the salt taken." *U. S.*

Uses.—Quinine urea hydrochloride is the most suitable of all the official salts of the alkaloid for hypodermic administration on account of its free solubility and of its neutral reaction. It is, therefore, widely employed in the treatment of the severer types of *malaria,* where the drug must be given subcutaneously, as well as in other conditions where large doses are required. In 1907 Thibault (*Journ. of the Arkansas Medical Soc.,* Sept., 1907), from observing the local effects following the hypodermic administration of this salt, was led to investigate the anesthetic properties of the quinine salts and found that all of the soluble ones produced local anesthesia, if in concentration of greater than 1.5 per cent. Since then quinine and urea hydrochloride as a local anesthetic for all sorts of medical and surgical conditions has been successfully employed by a large number of practitioners. It is somewhat slower than cocaine and in equal solutions distinctly weaker, but because of its lower toxicity is often a remedy of great value. It may be employed in strengths of from 2 to 20 per cent., according to the purpose for which it is used. According to Closson, while inferior to cocaine in its action on nerve endings, it is superior for nerve blocking.

Dose, two to ten grains (0.13–0.65 Gm.).

QUININÆ HYDROBROMIDUM. U. S.

QUININE HYDROBROMIDE Quin. Hydrobr. [Quinine Bromide Quininæ Hydrobromas, U. S., 1890, Quinine Hydrobromate]

(quĭ-nī'næ hȳ-drō-brō'mĭ-dŭm)

"The hydrobromide [$C_{20}H_{24}O_2N_2.HBr + H_2O$ =423.16] of the alkaloid quinine. Preserve it in well-closed containers, protected from light." *U. S.*

Bromhydrate de Quinine Basique, *Fr. Cod.;* Mobobromhydrate de Quinine, *Fr.;* Chininum Hydrobromicum; Chininhydrobromid, Bromwasserstoffsaures Chinin, *G*

This official salt may be made by suspending 10 parts of quinine sulphate in 80 parts of water, boiling, and adding 3.4 parts of barium bromide dissolved in 20 parts of water, filtering, evaporating, and crystallizing. It may also be made by Leger's process, as follows: Quinine sulphate, commercial, crystallized, 40 parts; potassium bromide, dried and powdered, 11 parts; alcohol (80 per cent.), 400 parts; distilled water, 400 parts. Dissolve the sulphate in two hundred parts of alcohol by the aid of heat, add the potassium bromide, dissolved in thirty parts of distilled water, and continue the heat five or six minutes, in order to allow the potassium sulphate, which is formed, to acquire greater compactness, so that it will more readily settle. Filter off from the precipitate, and wash four times with fifty parts of boiling alcohol. Let the alcoholic solution cool, when a further small quantity of potassium sulphate will be deposited. The solution is then again filtered through white filtering paper, and evaporated on a water bath to one hundred parts. Next, four hundred parts of distilled water are poured on, and heat is applied until the hydrobromide is completely dissolved. After allowing the solution to stand in the cold for about twenty-four hours, the dish will be found filled with a compact crystalline mass. The crystals are transferred to a filter, allowed to drain, and dried by exposure to air. Heating would cause them to fuse. The product thus obtained amounts to about thirty parts of perfectly white quinine hydrobromide. By evaporating the mother water to one-third of its volume, about six parts more may be obtained. It is absolutely necessary, as has been already pointed out by Boille, to redissolve the hydrobromide in water as above stated, if the salt is to be obtained in white and bulky crystals. The above quantity of four hundred parts should not be diminished, for, if this were done, the salt would separate at first in the form of an oily liquid, and afterwards would form a crystalline crust. (*Répert. de Pharm.,* 1880, p. 390; *N. R.,* Jan., 1881.)

Properties.—It is in "white, light, silky needles; odorless, and having a very bitter taste. The salt effloresces on exposure to the air. One Gm. of Quinine Hydrobromide dissolves in 40 mils of water, 0.9 mil of alcohol, 7 mils of glycerin, 0.6 mil of chloroform, and in 23 mils of ether at 25° C. (77° F.); also in 3.2 mils of water at 80° C. (176° F.). Its saturated aqueous solution is neutral or not more than slightly alkaline to litmus, and when strongly acidulated with diluted sulphuric acid has a vivid blue fluorescence. Precipitate a saturated aqueous solution of the salt with sodium hydroxide T.S.; filter, supersaturate the filtrate with acetic acid, and then add chloroform and a little chlorine water, and shake the mixture; the chloroform assumes a reddish-brown color. Add 1 or 2 drops of bromine T.S. to 1 mil of an aqueous solution of Quinine Hydrobromide (1 in 100) and then add 1 mil of ammonia water; the liquid acquires an emerald-green color due to the formation of thalleioquin. Quinine Hydrobromide loses not more than 5 per cent. of its weight when dried to constant weight at 100° C. (212°

F.). Incinerate about 2 Gm. of Quinine Hydrobromide; not more than 0.05 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is not darker than light yellow (*organic impurities*). On the addition of 0.1 mil of nitric acid to this solution an orange color is produced, due to the liberation of bromine, but no deep color, fading to orange, is noticeable (*morphine*). Ten mils of an aqueous solution of the salt (1 in 50), acidulated with hydrochloric acid, is not rendered more than faintly turbid by a few drops of barium chloride T.S. (*sulphate*). The addition of a few drops of diluted sulphuric acid to 10 mils of a hot aqueous solution of the salt (1 in 20) produces no turbidity (*barium*). Dissolve 2.93 Gm. of Quinine Hydrobromide in 20 mils of distilled water at 65° C. (149° F.), in a test tube of about 80 mils capacity, add a solution of 1.5 Gm. of crystallized sodium sulphate in 10 mils of distilled water warmed to 65° C. (149° F.) and maintain the mixture at this temperature for half an hour, shaking it frequently and thoroughly in the stoppered tube. Then cool it to 15° C. (59° F.) and keep it at this temperature for two hours, shaking it occasionally. Now filter the liquid through a filter paper of 8 to 10 cm. diameter and complete the test for other cinchona alkaloids with 5 mils of the filtrate as directed under *Quininæ Sulphas." U. S.*

Uses.—There is a wide-spread belief that this salt acts somewhat differently from the other preparations of quinine. The proportion of hydrobromic acid is, however, too small to exert any influence upon the system; ten grains of quinine hydrobromide represents less than two grains of hydrobromic acid. The salt has achieved a high reputation in the treatment of *Graves's disease,* and certainly in many cases will cause at least a temporary amelioration of many of the nervous manifestations of this disorder.

Dose, from two to ten grains (0.13–0.65 Gm.).

QUININÆ HYDROCHLORIDUM. U. S., Br.

QUININE HYDROCHLORIDE Quin. Hydroch. [Quinine Chloride, Quininæ Hydrochloras U. S., 1890, Quinine Hydrochlorate]

(quĭ-nī'nē hī-drō-ȼhlō'rĭ-dŭm)

"The hydrochloride [$C_{20}H_{24}O_2N_2.HCl + 2H_2O = 396.71$] of the alkaloid quinine. Preserve it in well-closed containers, protected from light." *U. S.* "Quinine Hydrochloride, $C_{20}H_{24}N_2O_2,HCl,2H_2O$, is the hydrochloride of an alkaloid, quinine, obtained from the bark of various species of Cinchona." *Br.*

Muriate of Quinine; Chlorhydrate de Quinine Basique, *Fr. Cod.;* Chlorhydrate de Quinine, *Fr.;* Chininum hydrochloricum, *P. G.;* Chininhydrochlorid, Salzsaures Chinin, *G.;* Cloridrato di chinina, *It.*

This quinine salt was recommended for admission to the Br. Ph., 1885, by W. Martindale on account of its being more soluble in water and richer in quinine than is the sulphate. It may be readily prepared by treating the alkaloid with diluted hydrochloric acid, or by double decomposition between barium chloride and quinine sulphate. Quinine hydrochloride is in "white, silky, glistening needles; odorless, and having a very bitter taste. The salt effloresces when exposed to warm air. One Gm. of Quinine Hydrochloride dissolves in 18 mils of water, 0.8 mil of alcohol, 7 mils of glycerin, 0.7 mil of chloroform, and in 340 mils of ether at 25° C. (77° F.); also in 0.5 mil of water at 80° C. (176° F.). Its aqueous solution (1 in 20) is neutral or not more than slightly alkaline to litmus, and is not fluorescent, except when highly diluted, or when diluted sulphuric acid is added to it. Silver nitrate T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in nitric acid. Add 1 or 2 drops of bromine T.S. to 1 mil of a solution of Quinine Hydrochloride (1 in 100) and then introduce 1 mil of ammonia water; an emerald-green color is produced due to the formation of thalleioquin. Quinine Hydrochloride loses not more than 10 per cent. of its weight when dried to constant weight at 120° C. (248° F.). Incinerate about 2 Gm. of Quinine Hydrochloride; not more than 0.05 per cent. of ash remains. A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is not darker than light yellow (*organic impurities*); this solution is not colored red by the subsequent addition of a few drops of nitric acid (*morphine*). Ten mils of an aqueous solution of the salt (1 in 50) acidulated with hydrochloric acid is not rendered more than faintly turbid by a few drops of barium chloride T.S. (*sulphate*). The addition of a few drops of diluted sulphuric acid to 10 mils of an aqueous solution of the salt (1 in 20) produces no turbidity (*barium*). Dissolve 2.75 Gm. of Quinine Hydrochloride in 20 mils of distilled water at 65° C. (149° F.) in a test tube of about 80 mils capacity, add a solution of 1.5 Gm. of crystallized sodium sulphate in 10 mils of distilled water warmed to 65° C. (149° F.), and maintain the mixture at this temperature for half an hour, shaking it frequently and thoroughly in the stoppered tube. Cool it to 15° C. (59° F.) and keep it at this temperature for two hours, shaking it occasionally. Now filter the liquid through a filter paper of from 8 to 10 cm. diameter and complete the test for other cinchona alkaloids with 5 mils of the filtrate as directed under *Quininæ Sulphas." U. S.*

"White silky crystals, efflorescent in warm air. No odor; taste very bitter. Soluble in 36 parts of *water,* and in 2 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of chlorides. When to 10 millilitres of an aqueous solution (1 in 1000) 0.5 millilitre of *solution of bromine* and, after well shaking, 1 drop of *strong solution of ammonia* are added, a deep green coloration is produced. When 2 grammes are dissolved in a warm mortar in 20 *millilitres of water* at 60° C. (140° F.), 1 gramme of powdered non-effloresced *sodium sulphate* added, the mixture triturated, cooled, allowed to stand at exactly 15° C. (59° F.) for half an hour with occasional stirring, the crystals of quinine sul-

phate pressed, and the expressed liquid filtered, 5 millilitres of this filtrate, transferred to a dry test-tube and brought to a temperature of 15° C. (59° F.), yield, on the gradual addition of 6 millilitres of *solution of ammonia,* also at a temperature of 15° C. (59° F.), a precipitate which redissolves on rotating the tube (limit of other cinchona alkaloids). Dissolves in *sulphuric acid* and in *nitric acid* without coloration. 1 gramme dissolves in 7 millilitres of a mixture of 2 volumes of *chloroform* and 1 volume of *absolute alcohol.* Loses not more than 9.1 per cent. of its weight when dried at 100° C. (212° F.). Yields no characteristic *reactions* for barium or for sulphates. No appreciable ash." *Br.*

Only the compounds of quinine with the oxy-acids show the fluorescence in acid solution, none of the compounds of the haloid acids showing this reaction.

Quinine hydrochloride has a decided advantage over the sulphate in its greater solubility in water. It is, however, less soluble than the acid quinine hydrochloride.

Dose, two to ten grains (0.13–0.65 Gm.).

Off. Prep.—Tinctura Quininæ, *Br.;* Vinum Quininæ, *Br.;* Elixir Ferri, Quininæ et Strychninæ, *N. F.;* Syrupus Phosphatum cum Quinina et Strychnina, *N. F.*

QUININÆ SALICYLAS. U. S.

QUININE SALICYLATE Quin. Salicyl.

(quĭ-nī'næ săl-ĭ-cĭ'lăs)

"The salicylate [$C_{20}H_{24}O_2N_2.C_7H_6O_3 + H_2O = 480.28$] of the alkaloid quinine. Preserve it in well-closed containers, protected from light." *U. S.*

Salicylate de Quinine Basique, *Fr. Cod.;* Salicylate de Quinine, *Fr.;* Chininsalicylat, Salicylsaures Chinin, *G.;* Salicilato quinico, *Sp.*

Preparation.—Quinine salicylate may be made by adding a solution made by dissolving 3.9 parts of sodium salicylate in 30 parts of water, to a hot solution made by dissolving 10 parts of quinine sulphate in 75 parts of boiling water. The precipitate is collected, washed and dried and recrystallized from its solution in alcohol.

Properties.—It is officially described as in "colorless, odorless needles, having a bitter taste, permanent in the air. It often assumes a pinkish color on keeping. One Gm. of Quinine Salicylate dissolves in 14 mils of alcohol, 13 mils of glycerin, 25 mils of chloroform, and in 160 mils of ether at 25° C. (77° F.); slightly soluble in water. Its saturated aqueous solution is alkaline to litmus and when this solution is treated with a drop of ferric chloride T.S., a violet color develops. Add 1 or 2 drops of bromine T.S. to 10 mils of an aqueous solution of Quinine Salicylate and then introduce an excess of ammonia water; an emerald-green color is produced due to the formation of thalleioquin. Quinine Salicylate loses not more than 5 per cent. of its weight when dried to constant weight at 100° C. (212° F.). Incinerate about 2 Gm. of Quinine Salicylate; not more than 0.05 per cent. of ash remains. Shake about 0.4 Gm. of the salt with 20 mils of distilled water and 1 mil of nitric acid; separate portions of 10 mils each of the filtered solution are not rendered more than slightly turbid by the addition of a few drops of barium chloride T.S. (*sulphate*), nor more than slightly opalescent by a few drops of silver nitrate T.S. (*chloride*). Mix 2.21 Gm. of Quinine Salicylate in a separator with 10 mils of distilled water, add 5 mils of ammonia water, and shake the liquid with three successive portions of 25, 20 and 10 mils, respectively, of ether. Evaporate the combined ether solutions to dryness on a water bath, dissolve the residue in 20 mils of alcohol, dilute it with 50 mils of hot distilled water, and neutralize the liquid with normal sulphuric acid V.S., using methyl red T.S. as indicator. Evaporate it to dryness on a water bath, powder the residue, mix it with 20 mils of distilled water in a test tube, and complete the test for other cinchona alkaloids as directed under *Quininæ Sulphas." U. S.*

Uses.—Quinine salicylate represents approximately 27 per cent. of salicylic acid, and 69 per cent. of anhydrous quinine. It is believed by many practitioners to be a valuable remedy in the advanced stages of an *acute rheumatism,* in *subacute rheumatism,* and in mild *gouty* conditions, but the proportion of salicylic acid seems too small to exercise any pronounced effect on the system.

Dose, from five to ten grains (0.32–0.65 Gm.).

QUININÆ SULPHAS. U. S., Br.

QUININE SULPHATE Quin. Sulph.

(quĭ-nī'næ sŭl'phăs)

"The sulphate [$(C_{20}H_{24}O_2N_2)_2.H_2SO_4 + 7H_2O = 872.62$] of the alkaloid quinine. Preserve it in well-closed containers, protected from light." *U. S.* "Quinine Sulphate, $(C_{20}H_{24}N_2O_2)_2,H_2SO_4,7\frac{1}{2}H_2O$, is the sulphate of an alkaloid, quinine, obtained from the bark of various species of Cinchona." *Br.*

Sulfas Quinicus; Disulphate or Basic Sulphate of Quinia, Sulfate de Quinine Basique, *Fr. Cod.;* Chininum Sulfuricum, *P. G.;* Chininsulfat, Schwefelsaures Chinin, *G.;* Solfato di chinina, *It.;* Sulfato quinico basico, *Sp.*

No process is given in the U. S. Pharm. for preparing quinine sulphate; that of the U. S. P., 1870, will be found in detail in the *U. S. D.,* 17th ed., p. 1141. The process, briefly stated, is to exhaust cinchona bark by boiling with water acidulated with hydrochloric acid and adding milk of lime in excess. The quinine is precipitated with lime, and the dried precipitate digested with boiling alcohol; the alcoholic solution of quinine is evaporated, and the mass dissolved in water acidulated with sulphuric acid. The hot solution is treated with animal charcoal to decolorize it, and then set aside to crystallize.

Pelletier proposed to substitute oil of turpentine for alcohol in the ordinary process for procuring quinine sulphate. The impure quinine, precipitated by lime from the acidulous

decoctions, after being washed, pressed, and dried, is digested with the oil, which dissolves the quinine. The solution thus obtained is agitated with water acidulated with sulphuric acid, by which quinine sulphate is formed. The oil, separating, rises to the top, and is removed for future use, and the aqueous solution of the salt is evaporated, and treated as in the original process. A disadvantage of this method is said to be that the oil does not completely exhaust the precipitate. A similar process has been employed here and in England, either fusel oil or petroleum benzin, or sometimes kerosene being substiuted for oil of turpentine. In this instance, however, the solvent is added to the impure quinine, without separation from the acidulated decoction from which it was precipitated by lime. The mixture being well agitated, the fusel oil or benzene dissolves the alkaloids, and, rising to the surface of the liquid, is drawn off by a siphon. The solution thus drawn off is treated as above with water acidulated with sulphuric acid, and the process is completed in the same manner. (See *P. J.*, xiv, 29, 92, and 139.)

When barks containing the alkaloids *cinchonidine* and *quinidine* are used, as their sulphates are much more soluble than that of quinine, it follows that in the mother waters left after the crystallization of quinine sulphate there will be found a portion of cinchonidine or quinidine sulphate, or of both. In fact, there is generally, under these circumstances, more or less of the sulphates of the four alkaloids, quinine, cinchonine, quinidine, and cinchonidine, all of which are contained in many barks, and, besides these, a portion of amorphous alkaloid, incapable of crystallization, probably resulting, in part at least, from the heat employed in the process. These may in a great degree be separated through their different solubilities in water. Quinine sulphate, being least soluble, will first crystallize, afterwards the cinchonidine or quinidine salt, and finally that of cinchonine, which is the most soluble, while the uncrystallizable salt will remain in solution, and may be obtained in the amorphous state by evaporation to dryness.

Properties.—"Quinine Sulphate occurs in white, silky, light, flexible, glistening crystals, making a very light and easily compressible mass, or as hard, prismatic, monoclinic needles; odorless, and having a persistent, very bitter taste. It effloresces rapidly when exposed to dry air, and then becomes lusterless; when exposed to light, it acquires a brownish tint. One Gm. of Quinine Sulphate dissolves in 725 mils of water, 107 mils of alcohol, and 30 mils of glycerin at 25° C. (77° F.); also in 47 mils of water at 80° C. (176° F.), in about 12 mils of alcohol at 60° C. (140° F.); slightly soluble in chloroform or ether. It is freely soluble in a mixture of 7 volumes of chloroform and 4 volumes of dehydrated alcohol. Its saturated aqueous solution is neutral or not more than slightly alkaline to litmus, and, when acidulated with diluted sulphuric acid, develops a vivid blue fluorescence. When heated to 60° C. (140° F.), or when exposed to dry air, it loses all but two molecules of its water of crystallization. Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid. Add 1 or 2 drops of bromine T.S. to 10 mils of an aqueous solution of the salt (about 1 in 1000) and then introduce an excess of ammonia water; the liquid acquires an emerald-green color due to the formation of thalleioquin. Quinine Sulphate loses not more than 16.2 per cent. of its weight when dried to constant weight at 110° C. (230° F.). Incinerate about 2 Gm. of Quinine Sulphate; not more than 0.05 per cent. of ash remains. One Gm. of the salt dissolves completely when heated to 50° C. (122° F.) in 7 mils of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol, and the solution remains clear on cooling (*ammonium sulphate or other inorganic salts*). A solution of about 0.1 Gm. of the salt in 2 mils of sulphuric acid is not darker than light yellow (*organic impurities*); this solution is not colored red by the subsequent addition of a few drops of nitric acid (*morphine*). Dry Quinine Sulphate (which must be neutral or slightly alkaline to litmus) at 50° C. (122° F.) for two hours, and then agitate 1.8 Gm. of the dried salt with 20 mils of distilled water at 65° C. (149° F.) for half an hour. Allow the mixture to cool to 15° C. (59° F.), macerate it at this temperature for two hours with occasional shaking and then filter it through a filter paper of from 8 to 10 cm. in diameter. Transfer 5 mils of this filtrate to a test tube and mix it gently (without shaking) with 7 mils of ammonia water, which must contain not less than 10 per cent. nor more than 10.2 per cent. of NH_3, have a temperature of 15° C. (59° F.), and be added at once. A clear liquid is produced (*other cinchona alkaloids*). If the temperature during the maceration has been 16° C. (60.8° F.), 7.5 mils of ammonia water may be added; if 17° C. (62.6° F.), 8 mils may be added." *U. S.*

"Small, light, white, silky crystals. No odor; taste intensely bitter. Soluble in 800 parts of *water*, and in 65 parts of *alcohol* (90 per cent.). Aqueous solution exhibits a blue fluorescence. Entirely soluble in *water* acidified with a mineral acid. Yields the *reaction* characteristic of sulphates. When to 10 millilitres of an aqueous solution (1 in 1000) 0.5 millilitre of *solution of bromine* and, after well shaking, 1 drop of *strong solution of ammonia* are added, a deep green coloration is produced. Exposed to dry air the crystals effloresce until the water of crystallization is reduced from 7½ molecules to 2 molecules. Aqueous solution yields with *solution of ammonia* a precipitate soluble in *ether*. When 2 grammes, weighed after drying at 50° C. (122° F.), are digested at 60° to 65° C. (140°–149° F.) in a stoppered test-tube with 20 millilitres of *water* for half an hour, repeatedly shaken, then allowed to cool to 15° C. (59° F.), kept at that temperature for half an hour, stirred from time to time, the crystals pressed, and the expressed liquid filtered, then 5 millilitres of this filtrate, transferred to a dry test-tube and

brought to a temperature of 15° C. (59° F.), yield, on the gradual addition of 6 millilitres of *solution of ammonia,* also at a temperature of 15° C. (59° F.), a precipitate which redissolves on rotating the tube (limit of other cinchona alkaloids). 1 gramme dissolves in 7 millilitres of a mixture of 2 volumes of *chloroform* and 1 volume of *absolute alcohol.* No appreciable ash." *Br.*

The acid quinine salts possess fluorescent properties with the exception of those of the haloid acids. It has also been discovered that the presence of acetphenetidin conceals the fluorescence of sulphuric acid solutions of quinine. The diluted acids, and tartaric and oxalic acids in excess, dissolve the sulphate easily. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the official salt, and crystallizes from its solution with much greater difficulty. This is now considered by many as strictly neutral, and therefore entitled to the name of quinine sulphate, while the official salt contains two equivalents of base to one of acid, and is therefore a *quinine subsulphate* or *diquinine sulphate.* The latter name was adopted by the London College, and has been much used by chemical writers. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the name of quinine sulphate, originally given to the official salt, under the impression that it was neutral, was retained; and it has been accepted by the British Pharmacopœia. Hence has arisen a confusion of nomenclature, which must embarrass the student. The following statement may serve to clear up this confusion. There are at least three quinine sulphates that have been obtained, of which two are now official. The first of these,

$$(C_{20}H_{24}N_2O_2)_2H_2SO_4 + 7H_2O$$

is a "*diquinic sulphate,*" but is the official salt known as quinine sulphate, or *Quininæ Sulphas,* U. S.; the second, formed by dissolving this first in dilute sulphuric acid, has the formula

$$C_{20}H_{24}N_2O_2,H_2SO_4 + 7H_2O$$

and is the official quinine bisulphate, or *Quininæ Bisulphas,* U. S.; while the third, a still more acid sulphate,

$$C_{20}H_{24}N_2O_2,2H_2SO_4 + 7H_2O$$

may be obtained from a solution of quinine in excess of diluted sulphuric acid. This salt is not official. Quinine sulphate, owing to the ease with which it parts with its water of crystallization, is apt to mislead those who seek to determine its quality. Forty samples examined by A. J. Cownley showed results varying from 8.1 to 15.95 per cent. of water of crystallization. He recommends for adoption in the Pharmacopœia the air-dried salt, which contains two molecules of water (4.6 per cent.), as being constant in composition. Farr and Wright confirm Cownley's views, and object to "anhydrous" quinine sulphate, which has been proposed by some chemists as the standard, because it has the opposite fault of absorbing moisture. (*P. J.,* 1896, 525; also *P. J.,* 1897, 203.)

The official test (see page 938) is probably the most reliable of all to prove the presence of small quantities of other cinchona alkaloids. It is a modification of Kerner's (see *U. S. D.,* 19th edition, page 1045), and admits the presence of a trace of other alkaloids. This certainly is as pure as the quinine sulphate need be. To separate the remaining trace of alkaloids entirely would require too great an expense, in fact it would more than double the cost of the salt.

Quinine sulphate is decomposed by the alkalies, their carbonates, and the alkaline earths. In solution it affords white precipitates with potassium and sodium hydroxides, and ammonia, which are partly soluble in an excess of alkali. Quinine sulphate is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinine. The soluble salts of lead and of barium occasion precipitates; and that produced by the salts of barium is insoluble in the acids. The soluble salts of acetic, oxalic, tartaric, and gallic acids occasion more or less precipitation with solution of quinine sulphate without excess of acid. A solution of chlorine added to a solution of quinine sulphate and followed by the addition of ammonia water occasions an emerald-green color, and, in certain proportions, the deposition of a green precipitate. The green compound has received the name of *thalleioquin.* The drop of ammonia should be put in without agitation. According to Flückiger, 1-5000th part of quinine can thus be found. With bromine instead of chlorine the test is more delicate. Flückiger states that 1-20,000th part of the alkaloid can be detected. (See a paper by C. F. Zeller, *A. J. P.,* 1880, p. 385; *P. J.,* 1872, p. 901.) Some improvements in the thalleioquin test were suggested by LaWall (*A. J. P.,* 1912, p. 484), to obviate the difficulties frequently encountered, which were found to be principally due to oxyacids in the chlorine solution. This solution is frequently not freshly nor properly prepared. A much more delicate reaction is produced by the use of a reagent made by dissolving 0.5 Gm. of potassium bromate and 10 mils of hydrochloric acid in enough water to make 100 mils. With this reagent it was found possible (when using volumes as large as 100 mils of the solution being tested) to detect quinine in dilutions of 1-200,000. The procedure is as follows: Take 100 mils of suspected solution, add 5 to 10 drops of the reagent, agitate well and immediately add 10 drops of stronger ammonia water and mix thoroughly.

F. S. Hyde (*Proc. A. Ph. A.,* 1897, 704) states that a solution of calcium hypochlorite gives more satisfactory results in the thalleioquin test than either chlorine or bromine water, the results being more certain and brilliant. If, previously to the use of ammonia in the chlorine test, a concentrated solution of potassium ferrocy-

anide be added, a dark red color is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonine; and, though quinidine sulphate gives the same red color, this does not disappear as with the quinine salt, but is persistent. (Schwartzer, *J. P. C.*, 4e sér., iii, 475.) Quinine sulphate gives a reddish-brown precipitate with iodine dissolved in a solution of potassium iodide. It is possible that under some circumstances the galvanic current may be of service in detecting the alkaloid; a paper on the electrolysis of the salt will be found in the *J. P. C.*, 4e sér., xi, 16. For valuable comments on quinine sulphate tests, see *Proc. A. Ph. A.*, 1897, 705.

Adulterations.—Quinine sulphate has often been adulterated. The effects of adulteration may be produced by the variable quantity of water which quinine sulphate may contain, without any observable alteration in its sensible properties. Millon and Commaille, having exposed quinine sulphate to a very moist atmosphere at the temperature of about 16.6° C. (62° F.), found it always to increase in weight, so that a specimen of the salt, previously deprived of all of its water capable of being separated by heat, had in five days absorbed 28.77 per cent. of water, and another specimen dried after its precipitation simply by draining, and supposed to contain 18 per cent. of water, had in ten days absorbed 14 per cent. more, making its whole percentage of water 32, or about one-third of its weight. This is an important fact, and will explain to some extent the frequent variable effects from apparently the same quantity of the salt. It is easy to detect and to obviate this natural sophistication by exposing a suspected specimen to a heat of 115° C. (239° F.). The loss of weight will indicate the quantity of water not essential to the salt. This is now covered by the official limiting test for the amount of moisture. Calcium sulphate, and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin, caffeine, salicin, phlorizin, and the cinchonine sulphate, and sulphates of other cinchona alkaloids, are among the substances which are said to have been fraudulently added in former times, but such gross adulterants have disappeared from the market product. It is sometimes replaced by or mixed with other cinchona alkaloids. According to W. A. Puckner (*West. Drug.*, 1896, 393), nearly pure crystallized calcium sulphate in fine needle-shaped crystals has been exploited as tasteless quinine sulphate under the name of *flora china*.

By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations.

According to Calvert, a saturated solution of quinine sulphate in cold water gives with a solution of chlorinated lime a precipitate soluble in an excess of the latter, while a solution of cinchonine sulphate of the same strength, treated in the same manner, gives a precipitate which is insoluble in a great excess of the reagent. The same effect is produced with lime water, and with solution of ammonia, and solution of calcium chloride, while it furnishes a precipitate with a solution of cinchonine sulphate, yields none with a solution of quinine sulphate. Though commercial quinine sulphate frequently contains a portion of one or more of the other cinchona alkaloids, the salt is only slightly less efficacious on that account, as these alkaloids have been shown to possess similar therapeutic properties with those of quinine, and to be little inferior in strength to them.

Uses.—The fatuous persistence with which the American profession and public continue to prefer this salt is one of the peculiar problems of crowd psychology. It contains less quinine than the hydrochloride, is practically insoluble and has no possible advantages. (See *Quinina*, page 931.)

Dose, two to ten grains (0.13–0.65 Gm.).

QUININÆ TANNAS. U. S.

QUININE TANNATE Quin. Tann.

(quĭ-nī′nē tăn′năs)

"A compound of the alkaloid quinine with tannic acid, of somewhat varying composition and containing not less than 30 per cent. nor more than 35 per cent. of anhydrous quinine ($C_{20}H_{24}O_2N_2$). Preserve it in well-closed containers, protected from light." *U. S.*

"Quinine Tannate is a pale yellow or yellowish-white, amorphous powder; odorless and tasteless, or having not more than a slightly bitter and astringent taste. Quinine Tannate is slightly soluble in water, chloroform, or ether; somewhat more soluble in alcohol. When heated it melts to a purplish, viscous mass. Aqueous and alcoholic solutions of Quinine Tannate are colored blue-black by ferric chloride T.S. Quinine Tannate loses not more than 10 per cent. of its weight when dried to constant weight at 100° C. (212° F.). Incinerate about 0.5 Gm. of Quinine Tannate; not more than 0.3 per cent. of ash remains. Shake about 0.5 Gm. of Quinine Tannate with 50 mils of distilled water and 1 mil of nitric acid and filter the mixture. Ten mils of this filtrate is not colored by 1 mil of hydrogen sulphide T.S.; other portions of the filtrate, 10 mils each, do not become more than slightly turbid on the addition of a few drops of silver nitrate T.S. (*chloride*) or on the addition of a few drops of barium chloride T.S.

(*sulphate*). Shake about 2 Gm. of Quinine Tannate, accurately weighed, with three successive portions of 25 mils each of anhydrous ether, filter the ether solutions, and wash the filter with 10 mils of anhydrous ether. Upon the evaporation of the combined filtrates and washings and drying at 100° C. (212° F.), the residue does not exceed 0.5 per cent. (*uncombined quinine*).

"**Assay.**—Mix about 0.5 Gm. of Quinine Tannate, accurately weighed, in a separator with 10 mils of distilled water and 10 mils of ammonia water, and shake the mixture with 20 mils of ether, then with successive 10 mil portions of ether until the quinine is completely extracted. Upon the evaporation of the combined ethereal liquids and drying the residue to a constant weight at 100° C. (212° F.), the weight of the anhydrous quinine so obtained corresponds to not less than 30 per cent. nor more than 35 per cent. of the weight of the Quinine Tannate taken.

"The alkaloid obtained in the above assay responds to the identity tests under *Quinina.*" *U. S.*

Quinine tannate may be prepared by precipitating one part of quinine sulphate, dissolved in thirty parts of water acidulated with a few drops of sulphuric acid, with a solution of three parts of tannic acid dissolved in thirty parts of cold water, and then washing and drying the precipitate. For other methods of preparing the tannate, see *West. Drug.*, 1893, 352; *Ph. Centralh.*, 1894, 155; *Proc. A. Ph. A.*, 1894, 675. It has the advantage of possessing little taste, but doubts have been repeatedly expressed about its efficiency. At best, it is a feeble preparation, containing as found in commerce, from 22.6 to 34 per cent. of quinine, according to the investigations of the Council on Pharmacy and Chemistry, *J. A. M. A.*, Oct. 14, 1911, p. 1303.

Quinine tannate is one of the least efficacious of all the quinine preparations. It was introduced in the Pharmacopœia because its comparative lack of taste, due to its insolubility, makes it suitable for administration to children in suspension with some thick syrup.

Dose, one to ten grains (0.065–0.65 Gm.).

RESINA. U. S., Br.

ROSIN Resin. [Resin, Colophony]

(rẹ-sī'nạ)

"The residue left after distilling the volatile oil from the concrete oleoresin obtained from *Pinus palustris* Miller and from other species of *Pinus* (Fam. *Pinaceæ*)." *U. S.* "Resin is the residue left after the distillation of the oil of turpentine from the crude oleo-resin (crude turpentine) of various species of Pinus." *Br.*

Colophone ou Arcanson, *Fr. Cod.;* Résine blanche, Résine jaune, *Fr.;* Colophonium, *P. G.;* Kolophonium, Geigenharz Fichtenharz, *G.;* Colofonia, Pece greca, *It.;* Cologonia, Pez griega, *Sp.*

After the distillation of the volatile oil from the turpentine (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called *colophony*, but with us is commonly and now officially known by the name of *rosin*. It is the *Resina* of the U. S. and British Pharmacopœias. It is sometimes called *resina flava*, or *yellow rosin*. When this, in a state of fusion, is strongly agitated with water it acquires a distinct appearance, and is denominated *resina alba*, or *white rosin*. The ports from which rosin is shipped are Wilmington, N. C., Charleston, S. C., and Savannah, Ga. The exports of rosin in 1904 amounted to 2,585,108 bbls., valued at $6,621,870; and in 1905 to 2,310,275 bbls., valued at $7,069,084.

Common or *yellow rosin*, in its purest state, is beautifully clear and pellucid, but much less so as usually found in commerce. Its color is yellowish-brown with a tinge of olive, and more or less dark, according to its purity and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. It is completely liquid at 152.5° C. (306° F.), begins to emit bubbles of gas at 157.5° C. (316° F.), and is decomposed at a red heat. The official description is as follows: "Rosin usually occurs in sharp, angular, translucent, amber-colored fragments, frequently covered with a yellow dust, brittle at the ordinary temperature; fracture shiny and shallow-conchoidal; odor and taste slightly terebinthinate. It is freely soluble in alcohol, ether, benzene, glacial acetic acid, or fixed or volatile oils, it is also dissolved by dilute solutions of the fixed alkali hydroxides. Its alcoholic solution is acid to litmus. Specific gravity: 1.07 to 1.09 at 25° C. (77° F.). It is easily fusible and burns with a dense yellowish smoke. Incinerate about 2 Gm. of Rosin; not more than 0.05 per cent. of ash remains. The acid number of Rosin is not less than 150 (see Part III, Test No. 10)." *U. S.*

"Translucent, of a light amber color, compact, brittle, pulverisable; fracture shining; odor and taste faintly terebinthinate. Soluble in *alcohol* (90 per cent.), in *ether, benzene,* and *carbon disulphide.* Readily fusible; burns with a dense yellow flame and much smoke, leaving no appreciable ash." *Br.*

The composition of rosin is expressed by the formula $C_{44}H_{62}O_4$, which is the formula ascribed to *abietic anhydride.* Jean, however (*Chem. News*, xxvi, 207), has separated two other resinoid substances in addition to abietic acid. Lewkowitsch (*Chem. Analysis of Oils*, etc., 2d ed., 236) states that rosin also contains varying quantities of unsaponifiable matter—viz., hydrocarbons due to the partial breaking up of the acid on distilling the pine rosin. This may vary from 5 to 9 per cent. in the American rosin. For a paper on abietic acid by Mead and Kremers, see *Proc. A. Ph. A.*, 1893, 198. By shaking coarsely powdered rosin with dilute alcohol and warming, it is converted into *abietic acid*, $C_{44}H_{64}O_5$, obviously an hydroxide of the first. Rosin may be considered, therefore, as abietic acid anhydride, $C_{44}H_{62}O_4$. Rosin, when it is boiled with alkaline solutions, forms greasy salts of abietic acid, the so-called rosin soaps which

are used in admixture with other soaps. As the acid is dibasic, these salts contain two atoms of alkali metal in combination. Rosin, distilled by itself, yields the so-called "rosin-oil," of which two fractions are taken separately—the first that distilling under 360° C. (680° F.), and the second that over 360° C. (680° F.)—and some 31 per cent. of fixed gases. The lighter fraction is known commercially as *rosin essence*, and is, according to Renard (*J. Chem. S.*, Aug., 1884, p. 843), composed of hydrocarbons, representing almost all series, from the paraffin series to the terpenes, including pentane and hexane, amylene and hexylene, toluene, xylene, and cumene, the tetra- and hexa-hydrides of all three of these, terebenthene and cymene. Several aldehydes and acids of the fatty series, such as isobutyric and valeric, were also recognized. The heavier fraction, or rosin oil in the stricter sense of the word, is composed of polymers of the hydrocarbons C_nH_{2n-2}, which readily resinify by the absorption of oxygen. This accounts for the use of rosin oil as an adulterant of linseed oil in the manufacture of printers' ink. When distilled with superheated steam, rosin yields benzene and toluene. *Sylvic acid*, formerly considered to be a constituent of rosin, is now regarded as a decomposition product of abietic acid. Similarly *pinic* and *pimaric acids*, announced as found in rosin, are impure products, although the latter acid, or one of the same name, is found in galipot resin. Propionic acid has, according to Renard, been obtained in abundance from the tar produced by the destructive distillation of rosin. (*A. Pharm.*, 1886, p. 939.)

A. Tschirch and B. Studer determined the nature of the constituents of American rosin. According to Mohr, the principal plant yielding the turpentine from which the American rosin is obtained is *Pinus palustris* Mill.; to some extent also, *P. heterophylla* Ell.; rarely *P. echinata*, *P. Tæda* and *P. scropida*. The sample under examination (presumably from *P. palustris*) was completely soluble in the ordinary solvents for resin, including petroleum benzin, in which some other varieties of rosin are only partly soluble. Its alcoholic solution is strongly acid in reaction. Its sp. gr. at 15° C. (59° F.) was 1.090. Its composition was proved to be as follows:

1. Acids soluble in ammonium carbonate: *α-abietinic acid*, $C_{19}H_{28}O_2$, forming an insoluble lead salt, 30 per cent. *β-abietinic acid*, $C_{19}H_{28}O_2$, not forming a lead salt, 22 per cent. 2. Acid soluble in sodium carbonate: *γ-abietinic acid*, $C_{19}H_{28}O_2$, insoluble in ammonium carbonate, 31.06 per cent. 3. Volatile oil, 0.4 to 0.7 per cent. 4. Resen, 5 to 6 per cent.

The impurities amounted only to 0.1 per cent., the loss in operation, however, to 10 per cent. Fahrion having proposed a method for the differentiation of different rosins, based upon their relative solubility in petroleum benzin, the authors determined the amount of solvent necessary to dissolve 1 Gm. of rosin, freshly powdered, and old powder; also abietinic acids and the resen in petroleum benzin, with the following results:

Rosin, old powder, 1 Gm. required...	400 mils
Rosin, fresh, 1 Gm. required.....	60 mils
α-Abietinic acid, 1 Gm. required.....	500 mils
β-Abietinic acid, 1 Gm. required.....	100 mils
γ-Abietinic acid, 1 Gm. required.....	100 mils
Resen	50 mils

These results show that all the resin-acids, as well as the rosin, are more or less soluble in petroleum benzin, and that fresh rosin is more readily soluble than the isolated acids, a peculiarity which has also been noticed in the case of other bodies. On the other hand, old rosin is much less soluble in petroleum benzin than is fresh rosin. (*A. Pharm.*, Oct., 1903, 495–522.)

White rosin differs from the preceding only in being opaque and of a whitish color. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent. A new and very interesting class of derivatives from colophony or rosin has been prepared by Eugen Schaal, of Feuerbach, Germany, and introduced into commerce under the name of *ester gums*. These are the *glyceryl*, *methyl*, and *ethyl esters of abietic acid*, made by heating the resin acid and the alcohol under pressure until saponification takes place. The product is then distilled off under reduced pressure. These "ester gums" are being used to advantage as substitutes for copal, damar, and kauri gums in varnish making.

Uses.—Rosin is important as an ingredient of ointments and plasters, but is rarely used internally. It has been given in *chronic enteritis*, five grains of the powder. According to Olmstead, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (*A. J. P.*, xxii, 325.)

RESINA JALAPÆ. U. S. (Br.)

RESIN OF JALAP Res. Jalap.

(rẹ-sī'nạ jạ-lā'pæ)

"Jalap Resin is a mixture of resins obtained from Jalap." *Br.*

Jalapæ Resina, *Br.*; Résine de Jalap, *Fr. Cod.*; Jalapenharz, *G.*; Resina di gialappa, *It.*; Resina de jalapa, *Sp.*

* "Jalap, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each *a sufficient quantity*. Moisten the powder with *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having

closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced in weight to *two hundred and fifty grammes* [or 8 ounces av., 358 grains], and add the latter slowly, with constant stirring, to *three thousand mils* [or 101 fluidounces, 212 minims] of water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] each of hot water. After having drained off all of the liquid, transfer the resin to a porcelain dish and heat it to dryness on a water-bath." *U. S.*

"Exhaust coarsely powdered Jalap with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash with Distilled Water, and dry at a gentle heat." *Br.*

Extract of Jalap was formerly official. It has been dropped from both the U. S. and British Pharmacopœias. Resin of Jalap has taken its place in both authorities. (See *U. S. D.*, 19th edition, page 479.)

Properties.—Resin of jalap is officially described in the U. S. Pharmacopœia as in "yellow to brown colored masses or fragments, breaking with a resinous, glassy fracture and translucent at the edges, or as a yellowish-gray to yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. It is permanent in the air. Resin of Jalap is soluble in alcohol in all proportions; insoluble in carbon disulphide, benzene, or fixed or volatile oils. Its alcoholic solution is faintly acid to litmus. Add 1 Gm. of the powdered Resin to 10 mils of chloroform in a stoppered flask and shake the mixture occasionally during one hour. Then filter, evaporate the filtrate in a tared dish and dry the residue to constant weight at 100° C. (212° F.); it weighs not more than 0.3 Gm. Add 1 Gm. of the powdered Resin to 10 mils of ether in a stoppered flask and shake the mixture occasionally during one hour. Then filter, evaporate the filtrate in a tared dish and dry the residue to constant weight at 100° C. (212° F.); it weighs not more than 0.12 Gm. (*rosin, orizaba, or other resins*). It is slowly but completely soluble in 5 times its weight of ammonia water, and the solution does not become gelatinous on standing. When this solution is acidified with hydrochloric acid, only a slight turbidity appears (*rosin, guaiac, or other resins*). When Resin of Jalap is heated at 100° C. (212° F.), no material loss in weight is observed (*water*). When Resin of Jalap is triturated with distilled water, the latter does not become colored, none of the Resin dissolves (*soluble impurities*), and the water does not have a bitter taste (*aloin*). Shake 0.02 Gm. of Resin of Jalap with 5 mils of ether, filter and evaporate the ethereal filtrate on a piece of filter paper; no greenish-blue color is produced by the application of a drop of ferric chloride T.S. to the filter paper (*guaiac*). One Gm. of Resin of Jalap when dissolved in 50 mils of alcohol, containing 1 mil of phenolphthalein T.S., requires not more than 0.5 mil of half-normal alcoholic potassium hydroxide V.S. to produce a red color (*acid resins*). Dissolve 0.02 Gm. of Resin of Jalap in 2 mils of glacial acetic acid and add a few drops of sulphuric acid; the mixture does not acquire a pink color (*rosin*)." *U. S.*

"In dark-brown opaque fragments, translucent at the edges; brittle, breaking with a resinous fracture; readily reduced to a pale-brown powder. Characteristic odor; taste acrid. Readily soluble in *alcohol* (90 per cent.). When 1 gramme of the powdered Resin is triturated with 20 millilitres of *water* and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of *solution of sodium hydroxide*, boiled for a few moments and cooled, when acidified with *hydrochloric acid* may become opalescent but not immediately turbid (absence of certain other resins). Not more than 15 per cent. of the powdered Resin is soluble in *ether* (absence of scammony resin)." *Br.*

The U. S. resin, although pure enough for practical purposes, is still colored. To obtain it colorless, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered, should be packed in the bottom of the percolator. The coloring matter is thus left behind, and the resulting tincture, treated as directed in the process, yields the resin as white as starch. Resin of jalap consists of two portions, one of which is hard and insoluble in ether, the other is soft and soluble in that menstruum, the former constituting about 90 per cent. It is insoluble in oil of turpentine. (Squire.) For its chemical properties, see *Jalapa*. It was at one time supposed that the purgative properties resided chiefly, if not exclusively, in the hard resin, but experiments by John C. Long appear to prove that the soft resin is equally energetic.

Guaiac, rosin, and other resinous substances are said to be sometimes fraudulently added to the resin of jalap. Guaiac may be detected by the green color it produces when a few drops of solution of sodium or calcium chloride are added to an alcoholic solution of the suspected resin. (*J. P. C.*, 3e sér., x, 357.) When pure jalap resin is dissolved in an alkaline solution, it is not precipitated by the addition of sulphuric or hydrochloric acid, having been converted, through the agency of the alkali, into an acid soluble in water. All the adulterating resins yield precipitates under the same circumstances. The resins of scammony and of fusiform jalap act in this respect like the true jalap resin, but are distinguishable by being

wholly soluble in ether, while jalap resin is not. (*N. R. Pharm.*, No. 1, 1854.)

Power and Rogerson (*P. J.*, 1909, lxxxiii, p. 7) find that the products heretofore obtained from jalap as the active principle possesses the attributes of a homogeneous substance. They found the resin of jalap to be a body of very complex composition, but did not determine any single principle to which its purgative action might be attributed. (See *Jalap* for the chemistry of the resins.)

It is now generally believed that the resin of jalap is the sole purgative principle of jalap, the gummy extractive being either simply diuretic or wholly inert. To obviate the occasional harshness of the resin, it has been advised to triturate it with milk sugar, potassium sulphate, almond emulsion, or other substance calculated to separate its particles. It may be conveniently made into pills with mucilage or alcohol. (Hasselby, *P. J.*, 2d ser., vii, 231.)

Dose, two to five grains (0.13–0.32 Gm.).

RESINA PODOPHYLLI. U. S. (Br.)

RESIN OF PODOPHYLLUM Res. Podoph. [Podophyllin]

(rẹ-sĭ'nạ pŏd-ọ-phĭl'lī)

Podophylli Resina, *Br.;* Podophyllum Resin; Resin of May-Apple; Résine de Podophyllum Peltatum, *Fr. Cod.;* Podophyllinum, *P. G.;* Podophyllin, Podophyllumharz, *G.;* Podofillina, *It.;* Podofilino, *Sp.*

* "Podophyllum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Hydrochloric Acid, *ten mils* [or 162 minims]; Alcohol, Water, each, *a sufficient quantity.* Moisten the powder with *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced to the consistence of a thin syrup, and pour this slowly, with constant stirring, into *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of water, mixed with the hydrochloric acid and cooled to a temperature below 10° C. (50° F.). When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of cold water. Spread it in a thin layer upon a strainer and dry the Resin by exposure to the air, in a cool place, protected from the light. Should it coalesce during the drying, or aggregate into lumps having a glossy surface, break it into pieces, and powder it in a mortar. Preserve it in well-closed containers, protected from light." *U. S.*

"Podophyllum Rhizome, in No. 40 powder, 1000 *grammes;* Alcohol (90 per cent.), Distilled Water, Hydrochloric Acid, of each a sufficient quantity. Exhaust the Podophyllum with the Alcohol by percolation; recover the greater part of the alcohol by distillation; pour the resulting liquid into eight times its volume of Distilled Water acidified with one twenty-fourth of its volume of Hydrochloric Acid, constantly stirring; after twenty-four hours collect the deposited resin, wash with Distilled Water, and dry at a temperature not exceeding 40° C. (104° F.)." *Br.*

The British Pharmacopœia (1885) abandoned the use of hydrochloric acid, as it is not necessary if the tincture is evaporated to the consistence of *thick* honey. Hydrochloric acid was directed in the 1898 revision as it seems to aid the precipitation when the tincture is not so concentrated. The color and yield of resin of podophyllum may be made to vary by adding alum, acids, or other substances to the water. It darkens if dried with the aid of heat, and its color is indeed no indication whatever of its quality. The average yield of resin is about 5 per cent.

Resin of podophyllum has usually a light-brown color, an acrid bitter taste, and a slight odor of the rhizome. It consists of two resins, one soluble both in ether and alcohol, the other in alcohol only. The resin extracted by ether constitutes, according to John W. Cadbury, 75 per cent. of the whole (*A. J. P.*, July, 1858, p. 301), according to Harvey Allen, 80 per cent. (*Ibid.*, May, 1859, p. 206.)

For further description of the composition of these resins see *Podophyllum.* Gordon and Merrell (*Proc. A. Ph. A.*, 1902, p. 343) have proposed a method of valuing resin of podophyllum, based upon the content of picro-podophyllin and submit a method of assay.

Properties.—It is officially described as "an amorphous powder varying in color from light brown to greenish-yellow, turning darker when subjected to a temperature exceeding 25° C. (77° F.), or when exposed to light. It has a slight, peculiar odor and a faintly bitter taste. *It is very irritating to the eyes, and to mucous membrane.* It is soluble in alcohol with only a slight opalescence. The alcoholic solution is faintly acid to litmus. Not less than 75 per cent. of Resin of Podophyllum is soluble in ether and not less than 65 per cent. is soluble in chloroform. A hot aqueous solution of Resin of Podophyllum deposits most of its contents on cooling, and if the cooled liquid is filtered, the filtrate has a bitter taste, and turns brown upon the addition of a few drops of ferric chloride T.S. It is soluble in potassium or sodium hydroxide T.S., forming a deep yellow liquid, which gradually becomes darker on standing, and from which the Resin is reprecipitated by acids. Add 0.4 Gm. of Resin of Podophyllum to 3 mils of 60 per cent. alcohol, introduce 0.5 mil of potassium hydroxide T.S., and gently shake the

mixture; it does not gelatinize (*difference from Resin obtained from Podophyllum Emodi*). Resin of Podophyllum yields not more than 1.5 per cent. of ash." *U. S.*

"An amorphous powder, varying in color from pale yellow to deep orange-brown. Taste bitter. Entirely or almost entirely soluble in *alcohol* (90 per cent.) and in *solution of ammonia;* precipitated from the former solution by *water,* from the latter by acids. Partly soluble in *ether.* Ash not more than 1 per cent." *Br.*

The official resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. For discussion of the solubilities of the fresh resin, see G. M. Beringer (*A. J. P.,* 1894, 11). The name *podophyllin,* given to it by the eclectic practitioners, who have long been in the habit of using this resin, is inappropriate, and should be abandoned.

Lohmann (*Proc. N. J. Pharm. Assoc.,* 1896, 51) states that the fresh drug does not yield as large a percentage of resin as the same drug would if tested after being stored for several years; his experiments led him to the conclusion that in the order of value of resin of podophyllum obtained by various methods, that made by precipitation with water alone came first, that made by the U. S. P. process second, and that made by precipitation with solution of alum last. Dohme and Kelly (*D. C.,* 1903, 251), replying to statements in a paper by Lohmann (*Proc. A. Ph. A.,* 1903, 317) regarding the yield of resin from podophyllum, state that: 1, the yield from the method of pouring an alcoholic extract into water was 5 per cent.; 2, from pouring an alcoholic extract into acidulated water 5.5 per cent., and 3, from pouring an alcoholic extract into acidulated water containing 5 per cent. of alum, 4.9 per cent. See also *Podophyllum,* page 880. The color by process 1, is grayish-white; 2, light brown; 3, greenish-yellow. The value of resin of podophyllum is accurately estimated by the percentage of podophyllotoxin that it yields. Nearly all of the resin of podohyllum in commerce is made by the alum process, has a deep yellow color and is not wholly soluble in alcohol.

There has been much difference of opinion as to the relative activity of the two resins composing it, some maintaining that both are active, others that the activity resides mainly, if not exclusively, in the resin soluble in ether. It is difficult to resist the evidence of the experiments of Cadbury, who states in the paper above referred to that, while half a grain of the ethereal resin acted energetically, and a cathartic effect was produced by even one-fourth of a grain, the portion insoluble in that menstruum was given in the dose of one grain without any effect whatever. Moreover, this evidence was subsequently confirmed by the experiments of F. B. Power. (*A. J. P.,* xlvi, 227.) It is asserted by Power, and confirmed by Maisch (*Ibid.,* 226), that the purgative principle of podophyllum is soluble in hot water. The researches of Power (*A. J. P.,* l, p. 369), Maisch (*P. J.,* 1880, p. 621), Quereschi (*Ber. d. Chem. Ges.,* xii, p. 683), and Podwyssotzki have established the fact that podophyllum does not contain berberine or any alkaloid, and that its activity is due to principles in the resins. (See *Podophyllum.*)

Uses.—Resin of podophyllum is a mixture of the active and inert principles of the rhizome. Resin of podophyllum is a powerful cathartic, occasionally producing some griping and nausea, but capable of being favorably modified by combination, and of being very usefully employed in connection with other cathartics, to give them increased energy. It was at one time supposed to be especially cholagogue, but this belief has been of late discredited. A small proportion of extract of belladonna or hyoscyamus mitigates its irritant action. Care must be taken in handling it in quantity, as it is a powerful irritant, frequently producing conjunctivitis.

Dose, one-eighth to one-fourth of a grain (0.008–0.016 Gm.).

RESINA SCAMMONIÆ. U. S. (Br.)

RESIN OF SCAMMONY Res. Scamm.

(rę-sĭ'nȧ scam-mō'nĭ-æ)

"Scammony Resin is a mixture of resins obtained from Scammony Root or from Orizaba Jalap Root." *Br.*

Scammoniæ Resina, *Br.,* Scammony Resin; Résine de Scammonée, *Fr. Cod.;* Scammoniaharz, *G.;* Resina di scammonea, *It.*

* "Scammony Root in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity.* Moisten the scammony root with sufficient alcohol, pack it in a cylindrical percolator, then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced to the consistence of thin syrup, and pour this slowly, with constant stirring, into *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of hot water. When the precipitate has subsided, decant the supernatant liquid, wash

the precipitated Resin twice by decantation with fresh portions of *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] each of hot water and dry the Resin on a water bath." *U. S.*

"Exhaust the coarsely powdered Root with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash it with Distilled Water, and dry at a gentle heat." *Br.*

The U. S. IX and Br. Pharmacopœia 1914 are in accord on the advisability of preparing *Resin of Scammony* from the dried root. This result has been brought about by the practical inability to secure pure resin of scammony from the countries in which the plant grows. Adulteration and sophistication for centuries have at last wrought havoc and the pharmacopœias have been compelled to make scammony resin from scammony root. For an account of the collection of scammony and the sophisticatons and adulterations, see *U. S. D.*, 19th edition, page 1099.

Resin prepared from the root and scammony obtained by evaporating the milky juice of the plant are practically identical. The elaborate researches of H. Spirgatis (*A. J. P.*, xlvi, 421) appear to have established the identity of the two products. A. Hess, however (*A. J. P.*, 1875, p. 210), states that the resin obtained from the root contains tannic acid. The advantage of the preparation is that the resin is obtained free from the inert matters with which it is often associated in the scammony of commerce. When pure virgin scammony can be procured, any preparation is unnecessary. Obtained according to the U. S. process, the resin is of a dirty greenish-brown color, with a feeble odor and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow color, and is without odor or taste, and retains its purgative property.

"Resin of Scammony consists of brownish, translucent masses or fragments, breaking with a glossy, resinous fracture; odor characteristic and agreeable. It is soluble in alcohol in all proportions, and not less than 95 per cent. is soluble in ether (distinction from *resin of jalap and resin of false scammony*). When triturated with water, it does not form an emulsion. Ammonia water and solutions of the alkali hydroxides dissolve it with the aid of gentle heat, and from these solutions the Resin is not reprecipitated by dilute acids. Its solution in alcohol does not give a blue color with ferric chloride T.S. or with solution of hydrogen dioxide (*guaiac*). Sulphuric acid does not turn red when stirred in a porcelain dish with an equal weight of Resin of Scammony (*rosin*). Resin of Scammony yields not more than 1 per cent. of ash." *U. S.*

"Brownish, translucent, brittle fragments, breaking with a resinous fracture; readily reduced to a pale-brown powder. Characteristic, agreeable odor; taste acrid. Readily soluble in *alcohol* (90 per cent.). When 1 gramme of the powdered Resin is triturated with 20 millilitres of *water* and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of *solution of sodium hydroxide*, boiled for a few moments and cooled, when acidified with *hydrochloric acid*, may become opalescent but not immediately turbid (absence of certain other resins). Not less than 75 per cent. soluble in *ether*." *Br.*

The resin of scammony is liable to adulteration. Jalap resin may be detected by its partial insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test for common rosin or colophony, producing instantaneously with this substance an intense red color, while with the resin of scammony it causes no immediate change. For the tests for guaiac, the reader is referred to that article on p. 536. (See also *A. J. P.*, xxiv, 158.) The presence of other resins may be known by the precipitates yielded when sulphuric acid is added to the alkaline solution, the resin of scammony agreeing with that of jalap in not affording a precipitate under such circumstances. Chas. Bullock has found the resins of scammony, of jalap, and of podophyllum to be insoluble in benzene, thus enabling any resin soluble in this liquid, which may be employed in the sophistication, to be readily detected. When rubbed with unskimmed milk, the resin of scammony forms a uniform emulsion, which is not distinguishable from rich milk itself. This is a very excellent mode of administration. The resin should always be given either rubbed up with some mild powder or in emulsion.

L. Lutz (*Pharm. Ztg.*, 1912, xxiii, p. 232) states that the behavior of the resin with iodine when examined microscopically affords a method of distinguishing resin from a number of its substitutes and adulterants.

Uses.—Scammony resin is an energetic cathartic, likely to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who used it as a purgative and externally in skin diseases. On account of its occasional violence, it is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. It should be given in emulsion with mucilage, sugar, almonds, licorice, or other demulcent, and its disposition to gripe may be counteracted by the addition of an aromatic.

Dose, from four to eight grains (0.26–0.5 Gm.).

S., Br.;* Pilula Colocynthidis Composita, *Br.;* Pilula Colocynthidis et Hyoscyami, *Br.;* Pilula Scammonii Composita, *Br.;* Pulvis Scammonii Compositus, *Br.;* Pilulæ Aloes, Hydrargyri et Scammonii Compositæ, *N. F.;* Pilulæ Colocynthidis Compositæ, *N. F.;* Pilulæ Colocynthidis et Hyoscyami, *N. F.;* Tinctura Jalapæ Composita, *N. F.*

RESINÆ

RESINS

(rę-sĭ'næ)

The official *Resins,* with a single exception, constitute a peculiar class of preparations, made by exhausting the substances from which they are obtained by alcohol, and then precipitating the resinous matter from the tincture by the addition of water, which abstracts the alcohol by its stronger affinity. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it. This set of substances has been much employed by the practitioners styling themselves "eclectics," but with great lack of discrimination. They have applied names to these resinous precipitates which, in their proper scientific use, are employed to designate neutral proximate principles of plants, generally representing more or less completely the effects of the plants respectively on the system; as we say *columbin, quassin, santonin,* etc., themselves proper proximate principles, and representing the virtues, in part at least, of calumba, quassia santonica, etc., from which they are obtained, and from which they derive their names. By applying similar names to their precipitated resins, such as podophyllin, iridin, cimicifugin, etc., *i.e.,* to the impure resins obtained by precipitating the tinctures of podophyllum, iris versicolor, cimicifuga, etc., they justify the suspicion either that they ignorantly believe them to be in fact the active principles of these medicines respectively, or that, knowing better themselves, they seek to impose such a conviction upon the ignorant. The fact is that the substances thus obtained, and thus named, are impure resins, which may possibly contain more or less of the active principles mixed with them, but are not entitled to names which imply that they are distinct proximate principles themselves.

Resins are solid, brittle, of a smooth and shining fracture, or in powder and generally of a yellowish-brown color. When perfectly pure, they are probably inodorous and often insipid; but, as usually found, they have a slight odor, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0.92 to 1.2 They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are addition of water. With pure potassium and sodium hydroxides they unite to form soaps, which are soluble in water, and the same result takes place when they are heated with solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mostly soluble in ether and the volatile oils, and in alcohol; and their alcoholic and ethereal solutions afford precipitates upon the mutual decomposition, and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.

Losch recommends the following process for rendering the resins as white as possible. Boil together 5 parts of the resin, 1 of carbonate of potassium or of sodium, and 20 of water, until a perfectly homogeneous mass is obtained; allow this to cool, and pass into it sulphurous acid, which saturates the alkali, and precipitates the resin in white flakes. Finally, wash the precipitate well with water, and dry it. (*J. P. C.,* June, 1856, p. 465.)

RESORCINOL. U. S. (Br.)

RESORCINOL Resorcin. [Resorcinum, U. S. 1890, Resorcin]

(rę-sör'cĭ-nŏl)

"Metadihydroxybenzene. It contains not less than 99.5 per cent. of $C_6H_4(OH)_2$ 1 : 3(110.05). Preserve it in well-closed containers, protected from light." *U. S.* "Resorcin, or meta-dihydroxy-benzene, $C_6H_6O_2$, may be obtained by the interaction of fused sodium hydroxide and sodium metabenzene-disulphonate." *Br.*

Resorcinum, *Br.;* Metadioxybenzene, Metadihydroxybenzene; Résorcine, *Fr. Cod.;* Resorcinum, *P. G.;* Resorcin, *G.;* Resorcina, *It., Sp.*

Resorcinol is *metadihydroxybenzene,* while pyrocatechin is the *ortho* compound and hydroquinone the *para* compound. Hlasiwetz and Barth first obtained this organic body in 1864 by fusing galbanum resin with potassium hydroxide; it was subsequently obtained from sagapenum, asafetida, ammoniac, and gum acroides. According to Kopp, it is prepared by the destructive distillation of *brazilin,* or from the wash or mother waters obtained in its manufacture from Brazil-wood. It is now generally prepared by fusing sodium benzene-disulphonate with sodium hydroxide. It is important that the benzene which is used as the starting-point in its manufacture, be free from toluene.

Properties.—*Resorcinol* is a diatomic phenol, isomeric with *pyrocatechin* and *hydroquinone.* It crystallizes in prismatic crystals of the rhombic system, distilling at 276.5° C. (529.7° F.), easily soluble in water, alcohol, and ether, insoluble in chloroform and carbon disulphide. A small quantity treated with fuming sulphuric acid is dissolved, with the production of, first, an orange-yellow, then a greenish-blue, and finally a pure blue color. Bromine water precipitates its aqueous solution, *tribromresorcin* separating in minute crystals. Several of the compounds of resorcinol with phthalic anhydride have assumed great technical importance as dye-colors under the names of *fluorescein, eosin,* and *uranine.* Its trinitro derivative is *styphnic acid,* $C_6H(OH)_2(NO_2)_3$, which is also formed from many of the gum-resins by the action of nitric acid. Resorcinol combines with various principles. In this way arise *eucalyptoresorcinol, caffeoresorcinol,* etc. (see *P. J.,* xxi, 997); also a brown powder said to be composed of resorcinol and iodoform which has been commended by Biélaïew (*S. M.,* 1892) as a stimulant application to

foul *ulcers,* in *eczema,* etc. It is very irritant, and usually requires dilution (from 6 to 25 per cent.). It is officially described as in "colorless, or nearly colorless, needle-shaped crystals, or as a powder, having a faint, peculiar odor and a sweetish, followed by a bitter taste. It acquires a pink tint on exposure to light and air. One Gm. of Resorcinol dissolves in 0.9 mil of water and in 0.9 mil of alcohol at 25° C. (77° F.); also in about 0.2 mil of water at 80° C. (176° F.); freely soluble in glycerin or ether; slightly soluble in chloroform. Its aqueous solution (1 in 20) is neutral or only faintly acid to litmus. It melts between 109° and 111° C. (228.2° and 231.8° F.). The addition of a few drops of ferric chloride T.S. to 10 mils of an aqueous solution of Resorcinol (1 in 200) produces a bluish-violet color, changing to brownish-yellow on the addition of ammonia water (distinction from *catechol and quinol*). Dissolve 0.1 Gm. of Resorcinol in 1 mil of potassium hydroxide T.S. and then add a drop of chloroform; the mixture upon being heated assumes an intense, crimson color, and if a slight excess of hydrochloric acid is then added, the color changes to a pale straw-yellow. Incinerate about 2 Gm. of Resorcinol; not more than 0.05 per cent. of ash remains. Lead acetate T.S. produces no precipitate when added to an aqueous solution of Resorcinol (1 in 20) (*catechol*). An aqueous solution of Resorcinol (1 in 20) does not emit the odor of phenol when gently warmed." *U. S.*

"Colorless, shining, acicular or prismatic crystals. Faint odor; taste pungent and sweetish, followed by bitterness. Soluble in less than 1 part of *water,* or of *alcohol* (90 per cent.); very soluble in *ether,* and in *glycerin;* soluble in *olive oil;* slightly soluble in *chloroform.* Melting point 110° to 111° C. (230°–231.8° F.); at a higher temperature sublimes without residue and without evolving an odor of phenol. Alkaline solutions darken in color and exhibit a strong greenish fluorescence. A concentrated aqueous solution is colorless (absence of empyreumatic substances), and neutral or only slightly acid to *litmus;* it is unaffected by the addition of *solution of lead acetate* (absence of catechol). A weak aqueous solution is colored bluish-violet by *T. Sol. of ferric chloride,* the color changing to brownish-yellow on the addition of *solution of ammonia* (distinction from catechol and quinol). When 0.5 gramme is mixed with 2 millilitres of *solution of formaldehyde* and 2 millilitres of *solution of sodium hydroxide,* and the mixture heated to boiling, a deep red coloration is gradually developed." *Br.*

"Assay.—Dissolve about 1.5 Gm. of Resorcinol, accurately weighed, in sufficient distilled water to make 500 mils. Transfer 25 mils of the solution to a 500 mil, glass-stoppered flask having a long and narrow neck, add 50 mils of tenth-normal bromine V.S., and dilute with 50 mils of distilled water. Then add 5 mils of hydrochloric acid and at once stopper the flask. Shake the liquid and allow it to stand for one minute, then dilute it with 20 mils of distilled water, add 5 mils of potassium iodide T.S. and allow it to stand for five minutes. The titration of the liberated iodine with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator, shows not less than 99.5 per cent. of $C_6H_4(OH)_2$.

"Each mil of tenth-normal bromine V.S. corresponds to 0.001834 Gm. of $C_6H_4(OH)_2$. Each gramme of Resorcinol corresponds to not less than 542.5 mils of tenth-normal bromine V.S." *U. S.*

Its official assay is based upon the following reaction:

$$C_6H_4(OH)_2 + 3Br_2 = C_6HBr_3(OH)_2 + 3HBr.$$

The excess of bromine is determined indirectly by titration with sodium thiosulphate V.S.

Dunlop (*P. J.,* 1909, lxxxii, p. 580) investigated the cause of coloration of resorcin. He found that moisture was the most important factor but that it apparently required light and heat to cause the change after it had once begun.

Uses.—Resorcinol appears in its physiological properties to be allied to phenol. It has marked antibacterial properties, and, according to Martin Cohn (*In. Dis.,* Berlin, 1882), a one per cent. solution of it is sufficient to arrest for a long time putrefactive changes; Cooper (*B. M. J.,* 1912, i, 1235) has shown that it is about one-third as actively germicidal as phenol. When given to the lower animals (Dujardin-Beaumetz, *B. G. T.,* ci, 113) it causes tremors, loss of consciousness, and epileptiform convulsions, which, when the dose has been sufficiently large, become more and more violent and associated with marked disturbances of respiration; this function is finally arrested and death ensues. During the spasms the temperature of the animal is distinctly elevated, but when there is quiet narcosis it may fall much below the normal. The urine becomes olive green, deepening into blackish. So far as we know, no case of fatal poisoning in man has been recorded. The largest therapeutic doses produce flushing of the face, with giddiness and buzzing in the ears and some quickening of the breathing and pulse, followed after a time by violent perspiration. Sixty grains caused in man giddiness, violent perspiration with marked anxiety, ending in collapse and unconsciousness. Andeer (*Cb. M. W.,* 1881) took about one hundred and fifty grains of resorcinol dissolved in a pint of water during fifteen minutes. After disturbance of cerebration and of the special senses, he fell into a condition of collapse, with cold extremities, epileptiform convulsions, opisthotonos, loss of consciousness, and marked irregularity of the respiration. Consciousness did not return for five hours.

Resorcinol has been used in medicine as an intestinal antiseptic in *enteritis,* but is probably of no service. In *gastritis* it may exercise some effect but is probably inferior to phenol. Because of its lower toxicity it is frequently employed in gastric lavage or as a wash in *nasal catarrh, chronic colitis, leucorrhea,* and other inflammations of the mucous membranes.

Schaffer (*B. K. W.*, 1910, p. 890) highly recommends as a surgical dressing, especially in *furuncles* and *cellulitis*, the use of 50 per cent. of alcohol with 2 or 3 per cent. of resorcinol added. He states that it has a remarkable effect in preventing suppuration. Elze (*Wochenschrift für Ther. and Hyg. des Auges*, 1909, xii, p. 202) asserts that a 1 or 2 per cent. resorcin ointment is useful in *cataract* and will often clear up opaque parts if not too far developed or too deeply located in the lens. The most important use of resorcin, however, is in the treatment of skin diseases. Many dermatologists attribute it with peculiar alterative properties towards the skin. In dilute solution, 1 or 2 per cent., it is antipruritic as well as antiseptic, and may be used in *acute eczema, urticaria*, and other inflammatory disorders of the epiderm. In stronger solution, 3 to 4 per cent., it is actively stimulating and is employed in the more sluggish conditions as *chronic eczema, seborrhea, psoriasis*, etc. Andeer has used it for its caustic effect in the treatment of *chancres, papilloma*, and *epitheliomata* in the form of a dusting powder.

Dose, three to five grains (0.2–0.32 Gm.).

RHEUM. U. S. (Br.)

RHUBARB

(rhē'ŭm)

"The rhizomes and roots of *Rheum officinale* Baillon, *Rheum palmatum* Linné, and the var. *tanguticum* Maximowicz (Fam. *Polygonaceæ*), and probably other species of *Rheum* grown in China and Thibet, deprived of most of the bark tissues and carefully dried. Preserve Rhubarb in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.* "Rhubarb is the rhizome of Rheum officinale, *Baill.*, and other species of Rheum, collected in China and Thibet, deprived of most of the cortex, and dried." *Br.*

Rhei Rhizoma, *Br.;* Rhubarb Root; Rhubarbe de Chine, *Fr. Cod.;* Rhubarbe, *Fr.;* Rhabarber, *G.;* Rabarbaro, *It.;* Ruibarbo, *Sp.;* Hainoung, *Chin.;* Schara-modo, *Thibet.*

Notwithstanding the length of time that *rhubarb* has been in use, it has not yet been determined from what precise plant the Asiatic drug is derived, the remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade is guarded, having prevented accurate information.

The terms *rha* and *rheon*, from the former of which were derived the names *rhabarbarum* and *rhubarb*, and from the latter the botanical title *Rheum*, were applied by the ancients to a root which came from beyond the Bosphorus, and which is supposed, though upon somewhat uncertain grounds, to have been the product of *Rheum rhaponticum* L., growing on the banks of the Caspian Sea and the Volga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not until the year 1732 that any probable information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species affording the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum Rhabarbarum*, a title which has since given way to *Rheum undulatum*. Subsequently, Kaau-Boerhaave obtained from a merchant, who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant producing the root sold by him. These, having been planted, yielded two species of Rheum. *R. undulatum*, and another which Linnæus named *R. palmatum*. Seeds transmitted by Mounsey from St. Petersburg to Hope, and planted in the botanic garden at Edinburgh, produced the latter species, and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described in 1767 by the younger Linnæus, two years after the appearance of Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favor of *R. palmatum* and *R. undulatum*. Colonel Przewalski concluded from personal observation that *R. palmatum* produces rhubarb; but the specimens of the root which he brought to St. Petersburg were stated by Dragendorff to be essentially different from true rhubarb. Claims have also been made from time to time for various other species of Rheum as sources of the drug. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants, was told that the leaves of the rhubarb plant were entirely different in shape, and the description he received of them corresponded more closely with those of *R. compactum* than any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg as those of the true Tartarian rhubarb. Wallich, superintendent of the botanical garden at Calcutta, received seeds that were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya Mountains and the highlands of Tartary. These produced a species not previously described, which Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Don and of Colebrooke, and has been ascertained to afford a root which, though purgative, is very unlike the official rhubarb. In 1867, French missionaries in Southeastern Thibet forwarded to Soubeiran of Paris, live specimens of a plant which they asserted to yield the true rhubarb, and Baillon subsequently described the flowering plant under the name of *R. officinale*. Its root resembles the true rhubarb, but the most careful cultivation has failed to obtain an identical product, and it cannot yet be considered as settled how far the commercial drug is obtained from it.

Senier found that, as raised in England, the root of *R. officinale* yielded less than half the percentage of extract obtained from the East Indian drug. In ten grain doses the extract was decidedly cathartic.

Tschirch in discussing the origin of Chinese Rhubarb has come to the conclusion that that obtained from Szetschwan, "southern" rhubarb, is derived from *Rheum officinale,* while that obtained from Kukunoor, "northern" rhubarb, is the product of *Rheum palmatum tanguticum* (*A. Pharm.,* 1907, p. 680; and *S. W. P.,* 1910, xlviii, 292).

Hosseus (*P. J.,* 1911, 87, p. 429) as a result of study of material furnished by Tafel, a Tibetan explorer, concludes that the best medicinal rhubarb is derived from *R. palmatum.* He believes that the belief that some of it comes from the *R. officinale* or other species is due to to the fact that Tibetans dig up the root of these other species of rhubarb for the purpose of deceiving Europeans.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles, composed of small and very numerous nowers, resembling those of the Rumex or dock. There is some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids, and it is frequently impossible to ascertain to which of the wild types the several garden varieties are to be referred. Lindley, *Flora Medica,* states that *R. rhaponticum, R. hybridum,* and *R. compactum,* and their hybrids, are the common garden rhubarbs.

R. officinale Baillon is described in the *Pharmacographia* "as a perennial, noble plant, resembling the common garden rhubarb, but of larger size. It differs from the latter in several particulars: the leaves spring from a distinct crown rising some inches above the surface of the ground; they have a subcylindrical petiole, which, as well as the veins of the under side of the lamina, is covered with a pubescence of short erect hairs. The lamina, the outline of which is orbicular, cordate at base, is shortly 5- to 7-lobed, with the lobes coarsely and irregularly dentate; it attains 4 to 4½ feet in length, and rather more in breadth. The first leaves in spring display before expanding the peculiar metallic red hue of copper."

Besides the species already mentioned, *R. leucorrhizum,* growing in the Kirgheeze desert in Tartary, *R. capsicum,* from the Altaï Mountains, *R. webbianum, R. speciforme,* and *R. moorcraftianum,* natives of the Himalaya Mountains and *R. crassinervium* and *R. hybridum,* cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives or possess properties more or less analogous to those of official rhubarb, though they have not entered into general commerce. In Java, the root of an indigenous species is used as a purgative. According to the analysis of J. H. Schmidt, it contains more chrysophan and emodin, and less chrysophanic and rheotannic acids, than does the official drug.

According to Aitchison (*Nature,* July 9, 1885), a rhubarb plant has been found in Northern Afghanistan in which there are usually only three enormous root leaves four feet long and five feet broad, lying flat upon the ground. The fruit is large and of a brilliant scarlet. The root is said to possess purgative properties, but the fruit is preferred, and is given in the form of a decoction.

Rhubarb is produced abundantly in the elevated lands of Tartary, about the lake Koko Nor, and is said to be cultivated in the neighboring Chinese province of Shen-see, and in that of Se-chuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb were exclusively derived; but the root is also collected in Bootan and Thibet, on the north of the Himalaya Mountains, and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. It is stated by Bell, who, on a journey from St. Petersburg to Pekin had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously, in tufts, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection until it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and the smaller branches, and then divided into pieces of a convenient size. In China these are bored with holes, and strung upon cords to dry—according to Bell, about the tents and on the horns of sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Bootan the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root, and Sievers states that a year sometimes elapses from the period of its collection before it is ready for exportation. A large proportion of its weight is lost in drying, according to some accounts four-fifths, according to others not less than seven-eighths. It is probably in order to favor the drying that the periderm is removed. Rhubarb which has been dried by artificial heat is known commercially as high dried and often can be recognized by its more or less blackened surface, and its heavy, scarcely fragrant odor. The trade in rhubarb is said to have formerly centred in the Chinese town of Si-nin, where a

Bucharian company or family was established which possessed a monopoly of this trade in consideration of a tribute paid to the government. At present rhubarb is chiefly purchased for the European trade at the town of Hankow, on the upper Yang-tse, the yearly export reaching over 5000 peculs (pecul = 133.33 lbs.). There were formerly two varieties of Asiatic rhubarb, the Russian and the Chinese, but at present little or no rhubarb finds it way overland to Europe. As long back as 1687, the Russian government subjected the export of rhubarb from China into Russia to official surveillance, and finally monopolized the trade entirely. At Kiakhta a very rigorous inspection of the drug was enforced, the selected pieces being finally sewed into linen sacks pitched and coated with hide. All the pieces which did not pass examination were committed to the flames, and the remainder was sent to St. Petersburg. This variety was sometimes called *Turkey rhubarb,* from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Anatolia. Inferior parcels of the root, which could not pass the inspection of the Russian authorities, were said to enter Russia by Tashkend, and to be known to the druggists of that country by the name of *Tashkend rhubarb.* Russian rhubarb no longer occurs in commerce. The description of it is given in the U. S. D., 19th edition, page 1061.

Chinese Rhubarb (*India Rhubarb, Rheum Sinense* vel *Indicum*) is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow color externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. The best pieces have a rather close and compact texture, and, when broken, present a ragged uneven surface, variegated with intermingled shades of dull red, yellowish, and white, which are sometimes diversified or interrupted by darker colors, and especially marked with dark lines so arranged as to form an internal ring of star-like spots. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process, and portions of the suspending cord are not unfrequently found remaining in the holes. According to Elborne (*P. J.,* xv, 497), Chinese rhubarb is the product of *R. palmatum* and *R. officinale,* the first variety has a red-grained fracture with white latticework veins, while the second variety has a longitudinal ramification of white veins with a black-grained fracture. Chinese rhubarb has a peculiar somewhat aromatic odor, and a bitter, astringent taste, is gritty when chewed, imparts a yellow color to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, defective from decay or improper preparation. These are usually lighter, and of a dark or russet color. Like all the other varieties of rhubarb, this is liable to be attacked by insects, and in almost every large parcel pieces may be found which have suffered from this cause. The Shensi variety is preferred, that of Sechuen and Kansuh are less valuable.

Chinese rhubarb is the only kind recognized by the U. S. P., and is officially described as "sub-cylindrical, barrel-shaped, or conical pieces known in commerce as 'rounds,' or in plano-convex pieces known in commerce as 'flats,' or in irregularly formed pieces, frequently with perforations. It is hard and moderately heavy; attaining a length of 17 cm. and a diameter of 10 cm., often cut in pieces of variable form and size; outer surfaces yellowish-brown, mottled, with alternating, longitudinal striæ of grayish-white parenchyma and reddish or brownish medullary rays; small stellate groups of fibro-vascular tissue and occasionally reddish-brown cork patches, smooth and sometimes covered with a bright, brownish-yellow powder; fracture uneven and granular, presenting a characteristic mottled appearance; odor aromatic, characteristic; taste characteristic, slightly bitter and astringent, gritty when chewed and tingeing the saliva yellow. Under the microscope, sections of Rhubarb show numerous thin-walled parenchymatous cells containing either a large number of starch grains or a single large rosette aggregate of calcium oxalate; scattered among the parenchyma are stellate groups of compound fibro-vascular bundles, the latter composed of narrow medullary rays separating the wedges, having large tracheæ in the outer part and separated by a prominent cambium from an internal phloem or sieve; among the grayish-white parenchyma of the inner bark occur narrow, yellowish-brown, irregular medullary rays. Not more than 15 per cent. of the drug should show a hollow or dark central area. The powder is bright orange-yellow to yellowish-brown; becoming red with alkalies; when examined under the microscope it exhibits calcium oxalate in rosette aggregates, mostly from 0.05 to 0.1 mm. in diameter, occasionally attaining a diameter of 0.15 mm.; starch grains numerous, somewhat spherical, single or 2- to 4-compound, each with a single cleft, from 0.002 to 0.02 mm. in diameter; tracheal fragments few, mostly reticulate, occasionally spiral. Boil 0.1 Gm. of powdered Rhubarb with 10 mils of an aqueous solution of potassium hydroxide (1 in 100); allow it to cool, filter, acidulate the filtrate with hydrochloric acid and shake it with 10 mils of ether; on standing the ethereal layer is colored yellow. Shake this ethereal solution with 5 mils of ammonia water; the latter is colored cherry-red (presence of *emodin*) and the ethereal layer remains yellow (presence of *chrysophanic acid*). Rhubarb, when exhausted with diluted alcohol, yields not less than 30 per cent. of dry extract. Rhubarb yields not more than 13 per cent. of ash." *U. S.*

"In compact, firm, cylindrical, barrel-shaped, conical or plano-convex pieces, often perforated, the perforation sometimes containing a fragment of cord. Surface rounded or slightly

angular, but not shrunken, marked with reddish-brown lines embedded in a whitish ground-substance; usually covered with a bright brownish-yellow powder. Fracture granular and uneven, the pinkish-brown fractured surface exhibiting numerous reddish-brown points and lines on a white ground-substance. For a short distance within the cambium the structure is radiate; within this there is a more or less distinct ring of closely approximated vascular bundles with central bast and radiating, reddish-brown medullary rays; in the parenchymatous cells abundant starch grains, an amorphous yellow substance and very large cluster-crystals of calcium oxalate. In powdered Rhubarb large cluster-crystals of calcium oxalate, often more than 100 microns in diameter, simple or compound starch grains, the single grains seldom exceeding 20 microns in diameter, fragments of reticulated vessels and of parenchymatous tissue, and small yellowish masses and globules which assume a reddish-pink color with *solution of ammonia;* it is free from added starch and from sclerenchymatous cells and fibres. Characteristic, somewhat aromatic odor; taste bitter, slightly astringent. Ash not more than 15 per cent." *Br.*

European Rhubarb.—In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years, and considerable quantities of the root were at one time brought into the market. At present it appears not to be imported into the United States.

English Rhubarb.—This formerly came in two forms. In one the root was cut and perforated in imitation of the Russian. The pieces were of various shapes and sizes, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. In the other, the so-called *stick rhubarb,* the pieces were somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. English rhubarb (from *Rheum rhaponticum*) is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is redder, and when broken exhibits a more compact and regular marbling, the pinkish lines being arranged like rays from the centre towards the circumference. The "star-like spots" are either wanting or very few and scattered. The powder also has a brighter yellow tint. The odor is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous, with little bitterness, and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colors the saliva. Few crystals of calcium oxalate are discoverable by means of the microscope. Much English rhubarb is obtained from *R. officinale,* and is put on the market in flat, concave, and convex pieces weighing from three to four ounces each. Externally the convex surface has deep longitudinal furrows and a longitudinal ramification of conspicuous veins, giving rise to an appearance of net-vein markings. In the centre of the concave surface is a small hole similar to that formerly seen in Russian rhubarb. On the inner surface the stellate markings resemble very closely those found in the East Indian rhubarb. The fracture of this form is not red, but shows a whitish parenchymatous tissue with blackish veins. When rapidly grown in rich soil, English rhubarb is lighter, more spongy, and less active than when slowly grown without high cultivation. It is probable that the powder is used to adulterate that of true Asiatic rhubarb, but of this we have no positive evidence.

French Rhubarb. Rhapontic Rhubarb. Crimea Rhubarb.—The rhubarb produced in France is, according to Guibourt, chiefly from *R. rhaponticum, R. undulatum,* and *R. compactum,* that of *R. palmatum,* which most closely resembles the Asiatic, having been found to degenerate so much as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighborhood of L'Orient, in the department of Morbihan, and the spot where it grows has, from this circumstance, received the name of *Rheumpole.* Two kinds were described by Guibourt, both under the name of *Rhapontic root*—one proceeding from the *R. rhaponticum,* growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned, cultivated at Rheumpole.

Rhapontic rhubarb is still found to some extent in European markets. Tschirch has proposed a ready method for detecting the admixture. It depends on the insolubility in ether of the crystalline principle rhaponticin or ponticin. (*A. Pharm.,* 1905, p. 443; and *S. W. P.,* xliii, p. 253.) Hesse has also made an elaborate study on the chemistry of rhapontic root grown in Austria. (*J. f. prakt. Chem.,* 1908, lxxvii, p. 320.)

The *rhapontic root* differs in section from true rhubarb by its distinctly radiated structure, unbroken by the peculiar arrangement (star-like spots) of the vascular tissue which occurs in true rhubarb.

Choice of Rhubarb.—In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a bright color, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odor decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb is often powdered, and colored yellow with turmeric, and the shavings left when Chinese rhubarb is trimmed for powdering, or to imitate the Russian, are applied to the same purpose. The stellate markings observed in the cut or

broken surface of the Chinese rhubarb has been believed by various pharmacologists to be of great practical value in determining the true character of the rhizome and especially in enabling a distinction between the Chinese and European rhubarb to be made. There has been a general concurrence with the statements of Tschirch that the star spots are never present in the root, occurring only in the rhizome. In an elaborate re-examination of this subject by Jakabhasy, however, the star spots were found in the root as well as in the root stock and also in the European as well as in the Asiatic rhubarb. Nevertheless, Jakabhasy states that it is possible to distinguish the two rhubarbs by the fact that in the European Rhubarb the star spots occur in greater number on the longitudinal section while in the Chinese rhubarb they are present on the transverse section, where they form a circle. He believes also that the superabundance of starch and the lack of crystals in the star spots are diagnostic of the European drug. When the rhubarb is powdered these characteristics are not available, under which circumstances the percentage of ash seems to be valuable. The Chinese rhubarb, unless of very inferior quality yields from 8 to 25 per cent.; the European 1.3 to 6 per cent. of ash. According to Jakabhasy, Shensi is the best, Shanghai the poorest, and Canton the intermediate variety of Chinese rhubarb. Of the European the English is the most, the French next, and the Austrian the least active.

Chemical Properties.—Rhubarb yields all its activity to water and alcohol. The infusion is of a dark reddish-yellow color, with the taste and odor of rhubarb, and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling the virtues of the medicine are impaired. The first examination of rhubarb yielding results of value was that of Schlosberger and Döpping. Besides extractive, tannic and gallic acids, sugar, starch, pectin, lignin, calcium oxalate and various inorganic salts, they discovered three coloring principles, holding an intermediate place between resin and extractive matter, being freely soluble in alcohol, and slightly so in water. Two of these were uncrystallizable, and denominated *brown resin* and *red resin*, or *phæoretin* and *erythroretin;* the other, crystallizable in granular crystals, and identical with *chrysophanic acid*, previously discovered by Rochleder and Heldt in the yellow lichen, or *Parmelia parietina* of Sprengel. Chrysophanic acid crystallizes in golden-yellow needles or plates melting at 102° C. (215.6° F.), and is soluble in ether, alcohol, or benzene. Alkalies also dissolve it, forming fine dark red solutions. Its formula is $C_{15}H_{10}O_4$, and it is now recognized as a derivative of anthracene, $C_{14}H_{10}$, and as closely related to alizarine, $C_{14}H_8O_4$. It bears to methyl-anthracene, $C_{14}H_9(CH_3)$, the same relation that alizarine bears to anthracene. Hence, on distilling it with zinc dust, methyl-anthracene is formed from it by reduction. (See *Chrysarobinum.*)

De La Rue and Müller (*J. Chem. S.*, x, 298) extracted from rhubarb *emodin*, which crystallizes in orange-colored prisms. Its formula is $C_{15}H_{10}O_5$, and it is a trioxy-methyl-anthraquinone. The relations of both this compound and chrysophanic acid to alizarine and anthracene will be better shown by writing their molecular formulas, as follows:

$C_{14}H_{10}$	$C_{14}H_6(OH)_2O_2$
Anthracene.	Alizarine.
$C_{14}H_5(CH_3)(OH)_2O_2$	$C_{14}H_4(CH_3)(OH)_3O_2$
Chrysophanic. Acid	Emodin.

Kubli (*Ph. Z. R.*, 6, p. 603) obtained results both confirmatory and explanatory of those already given. He found a glucoside, *chrysophan*, $C_{27}H_{30}O_{14}$, which, under the influence of dilute acids or ferments, splits up into chrysophanic acid and sugar, according to the reaction

$$C_{27}H_{30}O_{14} + 2H_2O = C_{15}H_{10}O_4 + 2C_6H_{12}O_6$$

also a characteristic tannic acid, *rheo-tannic acid*, $C_{26}H_{26}O_{14}$, which is decomposed by dilute acids into *rheumic acid*, $C_{20}H_{18}O_9$, and sugar. Chrysophan is a yellowish powder, abundantly present in rhubarb, soluble in water or alcohol, not in ether; rheo-tannic acid is a reddish brown powder, sparingly soluble in cold water. Kubli found further a colorless neutral compound, sparingly soluble in hot water, of the formula $C_{10}H_{12}O_4$, which he did not name. He stated that chrysophanic acid is not found in rhubarb, but is produced when the root is digested in water through the breaking up of the glucoside *chrysophan*, probably under the action of a ferment. This ferment he believes to be soluble in water, but insoluble in alcohol, and that on this account an alcoholic extract of the root can be evaporated without the formation of chrysophanic acid. On the other hand, it is to the presence of this ferment that he attributes the progressive deposition of chrysophanic acid from an extract of rhubarb prepared with diluted alcohol. (*Ph. Z. R.*, xxiv, 193.) O. Hesse (*Proc. A. Ph. A.*, 1896, 549) found in addition to chrysophanic acid, $C_{15}H_8O_2(OH)_2$, and emodin, $C_{15}H_7O_2(OH)_3$, a third crystalline principle, which he named *rhein*, and ascribes to it the formula $C_{15}H_8O_2(OH)_4$. Hesse calls attention to the relation these formulas bear to one another. Rhein forms microscopic yellowish-brown scales, is insoluble in water, ether, and benzene, but sparingly soluble in alcohol. It dissolves readily in aqueous solutions of the alkalies and alkaline carbonates, forming deep purple-red solutions. Hesse also finds an amorphous resinous substance, upon which, he states, the entire activity of rhubarb depends. Dragendorff states that from 11 to 17 per cent. of arabic acid and pectose are present in rhubarb. Hunkel (*Ph. Archiv.*, Nov., 1900, 201) reviewed the investigations of various chemists and isolated *tanoid* by the process of Löwe and a

phenolic body (unnamed) which had not been previously described.

The most important researches upon the constituents of rhubarb were made by Tschirch and Heuberger (*A. Pharm.*, Nov. 21, 1902, 596, 630, and *Ph. Ztg.*, Aug. 3, 1904, 651). Their conclusions are that rhubarb contains primarily two classes of substances. 1. *Tannoglucosides;* 2. *Anthraglucosides.* These two classes cannot be sharply separated from each other and are therefore associated together in all extractions. Both of these are characterized by their ready decomposition and conversion into secondary products, such conversion resulting even during the treatment of the drug with ordinary solvents. Thus, the ether extraction has been found to contain the products of the hydrolysis of the anthraglucosides, namely, chrysophanic acid, emodin and rhein. It is however not proven (indeed not even probable) that the tannoglucosides combine with the anthraglucosides to form so-called double glucosides. On the contrary, the indications are that these two classes of glucosides occur beside each other; furthermore, the relatively large quantity of tannoglucosides and their hydrolytic products is noteworthy and that, therefore, the activity of rhubarb is not attributable solely to the anthraglucosides; but the activity of the latter must be materially modified by that of the tannoglucosides. To what degree the primary tanno- and anthraglucosides have become hydrolyzed in the drug itself, it is difficult to determine; it is certain, however, that the drug contains a considerable quantity of free oxymethylanthraquinones, while it is probable that the formation of the secondary glucosides results during the extraction and manipulation of the extract.

Tschirch sums up the results of the investigation as follows: Aweng's *Double Glucoside* is in its essentials identical with tannoglucoside, but contains some anthraglucoside. Aweng's *Frangulic Acid* is a secondary product of the decomposition of tannoglucoside, containing variable quantities of anthraglucoside as impurity. Kubli's *Rheumtannic Acid* and Hunkel's *Tanoid* are identical with tannoglucoside, but less pure. Kubli's and Hunkel's *Rheum Acid* is identical with *rheum red,* and therefore a product of the hydrolysis of tannoglucoside. Schlossberger and Dopping's *Aporetin* and *Phaeoretin* are impure, difficultly soluble tannoglucoside. *Erythroretin* is a mixture of chrysophanic acid, emodin and rhein. Garot's *Erythrose* is *chrysamic acid. Rhein,* yielding only a diacetyl derivative, cannot be regarded as being tetraoxymethyl-anthraquinone. It has the composition $C_{15}H_8O_6$ (not $C_{15}H_{10}O_6$, Hesse) which formula corresponds to a methylene ether of a tetraoxyanthraquinone. Dragendorff's, Greenish's and Elborne's *Cathartic Acid* is an impure tannoglucoside, containing anthraglucosides and some albuminoid substances. Gilson's *Chrysophan* belongs to the anthraglucosides. Aweng's Secondary Glucosides are secondary, mostly difficultly soluble hydrolytic products of the primary tanno- and probably also of the anthraglucosides.

Finally, Tschirch determined that rhubarb contains no resins whatever; that the rheotannoglucosides and their products of decomposition and hydrolysis are devoid of purgative activity, and that such activity is due solely to the anthraglucosides and their derivatives. Rhubarb contains no other body besides the latter that has peristaltic effect on the intestinal tract.

As regards the rheo-tannoglucoside, its medicinal activity is confined to the tonic and mildly astringent effect produced on administering the drug. Tschirch (*Ph. Ztg.*, Aug. 3, 1904, 651) recommended a method for assaying rhubarb based on the volumetric estimation of the free oxymethylanthraquinones, dependent on the ease with which the anthraglucosides can be hydrolyzed with sulphuric acid. See also *Proc. A. Ph. A.*, 1905, 627.

There are other interesting principles in rhubarb. Some have been disposed to ascribe its odor to a volatile oil, but this has not been isolated. The calcium oxalate is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constitutes nearly one-third, and Queckett found between 35 and 40 per cent., while Brandes obtained only 11, Schrader only 4.5 parts in the hundred, and Dragendorff, in five samples analyzed, from 1.2 to 5.6 per cent. Little or no difference of composition has been found between the Russian and the Chinese rhubarb. The European contains but a small proportion of calcium oxalate, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapor of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other coloring principles. It yields precipitates with gelatin, most of the acids, ferric salts, lead acetate, mercurous nitrate, silver nitrate, stannous chloride, lime water, and solutions of quinine. Nitric acid occasions at first a turbidness, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.

For a method of detecting the presence of turmeric in powdered rhubarb by the influence of chloroform on the coloring principles of each of these substances, and of distinguishing through the same agency between the true Chinese rhubarb and that of European origin, the reader is referred to a paper, by W. L. Howie, contained in *A. J. P.* (Jan., 1874, 16), from *P. J.* (Nov. 15, 1873); see also *P. J.*, 1898, 126.

Uses.—Rhubarb contains cathartic principles of the anthraquinone series. It differs from drugs of this group—such as aloes, cascara, etc.

—in that it has a larger percentage of tannic acid. On account of the considerable quantity of tannin its purgative action is often followed by constipation. This sequence of effects has led to its use in the treatment of *diarrheas*, especially of the inflammatory type, on the theory that the catharsis it caused would evacuate the irritant *materies morbi*, and that its subsequent astringency would check the excessive secretion. The logic is plausible, but erroneous. As the action of its cathartic principles is limited to the lower bowel it has very little influence in cleaning out the smaller bowel which is the more frequently involved in acute *diarrheas*. In inflammations of the colon, such as *dysentery*, its use might appear more reasonable, but even here it is greatly inferior to less irritant laxatives because it acts chiefly by virtue of its local irritant influence. Rhubarb is also widely prescribed in atonic *dyspepsia* attended with *constipation*. It is frequently combined with an alkali, either magnesia or soda.

It sometimes occasions griping. Its coloring principle is absorbed, and may be detected in the urine. By its long-continued use the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses cathartic. It gives a yellow color to the alvine discharges.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. When so treated it is termed *torrefied rhubarb*. This mode of treatment has been sometimes resorted to in cases of *diarrhea*. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing *ulcers*. It is said to have proved purgative when sprinkled over a large ulcerated surface, and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

European rhubarb must be administered in double or treble the dose of true rhubarb to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal proportion of soap when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup, tincture, and fluidextract are also useful preparations. They are all official. The formula for *mixture of rhubarb and soda* which was largely used in New York at one time will be found in the National Formulary IV. The name was changed to *Mistura Rhei Composita*.

Dose, as a purgative, from twenty to thirty grains (1.3–2.0 Gm.); as a laxative and stomachic from five to ten grains (0.32–0.65 Gm.).

RHŒADOS PETALA. Br.

RED POPPY PETALS

(rhœ'ą-dŏs pĕt'ą-lą)

"Red-Poppy Petals are the fresh petals of Papaver Rhœas, *Linn.*" *Br.*

Corn Poppy, Corn Rose; Coquelicot, *Fr. Cod.;* Pavot rouge, *Fr.;* Wilder Mohn, Klapperrose, Llatschrosen, *G.;* Rosolaccio, *It.;* Amapola (Flor de), *Sp.*

The *red* or *corn poppy, Papaver Rhœas*, is distinguished by its hairy stem, which is branched, and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet color of its petals. It is a native of Europe, where it grown wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been naturalized in this country.

Its capsules contain the same kind of milky juice as that found in *P. somniferum*, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. Filhol has shown that the extract contains morphine, but in a proportion exceedingly minute compared with that in which it exists in opium. The petals are the official portion. They have a characteristic odor, and a mucilaginous, slightly bitter taste. By drying, they lose their odor, and assume a violet-red color. "Transversely elliptical, about five centimetres wide, bright scarlet, smooth and lustrous; margin entire. Characteristic, somewhat unpleasant odor; taste slightly bitter." *Br.*

Chevallier believed that he had detected a very minute proportion of morphine in an extract obtained from them; but Attfield seems to have determined satisfactorily the non-existence of morphine in the petals, having sought this alkaloid by three different processes, using a pound of the petals in each experiment, and failed to detect the least evidence of its presence. (*P. J.*, Oct., 1873, p. 291.) Their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet color, which they communicate to water, than for

their medicinal virtues According to Leo Meier, the coloring principles of the flowers are two acids, which he denominates *rhœadic* and *papaveric acids.* (See *A. J. P.*, xviii, 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections, but is now little esteemed except for its color.

An alkaloid was discovered in this species of poppy by O. Hesse, who proposed to name it *rhœadine.* It seems to pervade all parts of the plant, from which, as the first step in its preparation, an aqueous extract is prepared. This is treated with sodium carbonate, and repeatedly agitated with ether; the ethereal liquid is shaken with a solution of sodium bitartrate, and the mixture is precipitated by ammonia. The precipitate is washed with cold water, dried, and boiled with alcohol, by which coloring matter and another alkaloid in small quantity, probably thebaine, are removed. The residue, consisting mainly of rhœadine, is purified by combining it with acetic acid, treating with animal charcoal, and precipitating with ammonia. The alkaloid is in small white prismatic crystals, tasteless, fusible at 232.2° C. (450° F.), becoming brown at the same temperature and partially subliming. It is almost insoluble in water, alcohol, ether, chloroform, benzene, ammonia, solution of sodium carbonate, and lime water, but is dissolved by dilute acids, which produce colorless solutions. Its composition is represented by the formula $C_{21}H_{21}O_6N$. It does not appear to be poisonous. Hydrochloric and sulphuric acids, moderately concentrated, decompose and dissolve it, with the production of a purple color, which disappears under the action of the alkalies, but is restored by acids. One part of the alkaloid so treated produces a purple color with 10,000 parts of water, rose color with 20,000 parts, and a perceptible redness with 800,000 parts. This change is dependent upon the liberation from the rhœadine of a red coloring matter, while the isomeric *rhœagenine* remains. This forms small white tasteless prisms, which fuse at 223° C. (433.4° F.) and do not sublime, but are decomposed at higher temperatures. This is a very delicate test, by means of which the alkaloid may be detected in all parts of *Papaver Rhœas,* in the ripe capsules of the opium poppy, and in opium itself. It is said also to exist in Merck's prophyroxine. (*A. J. P.*, 1867, p. 122.) According to Hesse, the milky juice also contains *meconic acid.*

ROSA GALLICA. U. S. (Br.)

RED ROSE Rosa Gall.

(rō'ṣą găl'lĭ-cą)

"The dried petals of *Rosa gallica* Linné (Fam. *Rosaceæ*), collected just before the expansion of the flower. Preserve Red Rose in tightly-closed containers, protected from the light." *U. S.* "Red-Rose Petals are the fresh or dried unexpanded petals of Rosa gallica, *Linn.;* obtained from cultivated plants." *Br.*

Rosæ Gallicæ Petala, *Br.*, Red-rose Petals; Flores Rosarum Rubrarum; Rose rouge ou Rose de Provins, *Fr. Cod.;* Roses rouges, *Fr.;* Sammtrose, Zuckerrose, Französische Rose, Essigrosenblätter, *G.;* Rosa rossa, *It.;* Rosa roja (Flore de), Rosa rubra, *Sp.*

At one time pale rose or *Rosa centifolia* was official in addition to red rose or *Rosa gallica.* There is no uniformity on the subject in the several Pharmacopœias. The Pharmacopœia of the Netherlands and the French Codex still include both species. The German Pharmacopœia, on the other hand, specifies only the petals of *Rosa centifolia.* The British and Austrian Pharmacopœias are in unison with the U. S. Pharmacopœia in restricting the drug to *R. gallica.*

Rosa gallica is smaller than *R. centifolia* L., but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson color, and less numerous than in the *R. centifolia.* The stamens on thread-like filaments, and the villose styles bearing papillary stigmas, are numerous. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the south of Europe, and is cultivated in gardens throughout the United States.

The drug is officially described as "petals either separate or imbricated in small cones, broadly ovate, summit rounded and deeply notched, margin entire and somewhat recurved, base obtuse; externally of a purplish-red color except the light-brown claw; texture velvety; when dry, brittle; odor agreeable; taste astringent and slightly bitter. Under the microscope, transverse sections of the petals of Red Rose show the upper epidermal cells modified to conical papillæ and containing a purplish-red cell sap; a loose mesophyll composed of from 2 to 10 rows of cells among which are the fibro-vascular bundles with spiral tracheæ, and a lower epidermis of rectangular cells filled with a purple cell sap. Red Rose yields not more than 3.5 per cent. of ash." *U. S.*

"Usually in little cone-like masses, or sometimes separate and more or less crumpled. Petals velvety, deep purplish-red passing into brownish-yellow towards the base. Fragrant odor; taste slightly astringent." *Br.*

The petals should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odor, which is less fragrant than that of *R. centifolia,* is improved by drying. They have a velvety appearance, a purplish-red color, and a pleasantly astringent and bitterish taste.

An illustrated article on the structural characteristics of rose petals, whole and powdered, has been published by Hans Kramer in *B. P. G.*, 1907, xvii, p. 354.

Their constituents, according to Cartier, are tannin, gallic acid, coloring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassium, insoluble salts of lime, silica, and ferric oxide.

(*J. P. C.*, vii, 531.) According to Filhol, the astringency of red roses is ascribable less to tannic acid, of which they contain but a trace, than to *quercitrin*, which he obtained in notable proportion, and with which their color is probably connected. Rochleder found that in red roses the gallic acid is accompanied by quercitannic acid. They also contain much uncrystallizable sugar. (*Répert. de Pharm.*, Mai, 1863.) The sensible properties and medicinal virtues of the flowers are extracted by boiling water. Their coloring matter, according to Senier (*Y. B. P.*, 1877, p. 63), is an acid, which appears to form crystallizable salts with potassium and sodium, and amorphous ones with the heavy metals. Senier gives as the formula of the insoluble lead compound $Pb_2C_{21}H_{29}O_{30}$. Their infusion is of a pale reddish color, becoming bright red on the addition of sulphuric acid. As their color is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Uses.—Red rose is slightly astringent and tonic, and it was formerly thought to possess peculiar virtues. It it at present chiefly employed as affording an elegant vehicle for tonic and astringent medicines.
